    FROM example_topic TO example_table USING $transformation_lambda
WITH (
    BATCH_SIZE_BYTES = 1048576,
    FLUSH_INTERVAL = Interval('PT60S')
);
```

Lambda function

A message transformation lambda function takes a single structured parameter containing the message from the topic and returns a list of structures corresponding to the table rows for insertion.

Example:

```
$lambda = ($msg) -> {
  return [
    <|
      column_1: $msg._create_timestamp,
      column_2: $msg._data
    |>
  ];
};
```

In this example:

- `$msg` — the message received from the topic.
- `column_1` and `column_2` — the names of the table columns.
- `$msg._create_timestamp` and `$msg._data` — the values that will be written to the table. The value types must match the table column types. For example, if the `column_2` table column has the `String` type, the type of `$msg._data` must also be `String`.

The following fields are available in a topic message:

Attribute	Value type	Description
`_create_timestamp`	`Timestamp`	Message creation time
`_data`	`String`	Message body
`_offset`	`Uint64`	Message offset
`_partition`	`Uint32`	Message's partition number
`_producer_id`	`String`	Producer ID
`_seq_no`	`Uint64`	Message sequence number
`_write_timestamp`	`Timestamp`	Message write time

Testing lambda functions

To test a lambda function during development, you can simulate a topic message by passing a structure with the same fields that the transfer will provide. Example:

```
$lambda = ($msg) -> {
  return [
    <|
      offset: $msg._offset,
      data: $msg._data
    |>
  ];
};

$msg = <|
  _data: "value",
  _offset: CAST(1 AS Uint64),
  _partition: CAST(2 AS Uint32),
  _producer_id: "producer",
  _seq_no: CAST(3 AS Uint64)
|>;

SELECT $lambda($msg);
```

If a lambda function contains complex transformation logic, you can extract it into a separate lambda function to simplify testing.

```
$extract_value = ($data) -> {
  -- complex transformations
  return $data;
};

$lambda = ($msg) -> {
  return [
    <|
      column: $extract_value($msg._data)
    |>
  ];
};

-- You can test the extract_value lambda function like this

SELECT $extract_value('converted value');
```

- Data transfer

CREATE VIEW

`CREATE VIEW` defines a view with a given query.

A view logically represents a table formed by a given query. The view does not physically store the table but executes the query to produce the data whenever the view is accessed.

Syntax

```
CREATE VIEW [IF NOT EXISTS] <name>
[ WITH ( <view_option_name> [= <view_option_value>] [, ... ] ) ]
AS <query>
```

Parameters

- `IF NOT EXISTS` - when specified, the statement does not return an error if a view with the given name already exists.
- `name` - the name of the view to be created. The name must be distinct from the names of all other schema objects.
- `query` - the `SELECT` query, which will be used to produce the logical table the view represents.
- `WITH ( <view_option_name> [= <view_option_value>] [, ... ] )` specifies optional parameters for a view. The following parameters are supported:
  - `security_invoker` (Bool) causes the underlying base relations to be checked against the privileges of the user of the view rather than the view owner.

> **Note**
>
> When choosing a name for the view, consider the common schema object naming rules.

Notes

The `security_invoker` option must always be set to true because the default behavior for views is to execute the query on behalf of the view's creator, which is not supported yet.

The execution context of the view's query differs from the context of the enclosing `SELECT`. It does not see previously defined `PRAGMA`s, named expressions, etc. Most importantly, users must specify the tables (or views) they select from in the view's query by their schema-qualified names. You can see in the examples that the absolute path like `/domain/database/path/to/underlying_table` is used to specify the table from which a view reads data. The particular context of the view's query compilation might change in the upcoming releases.

If you wish to specify column names that you would like to see in the output of the view, you might do so by modifying the view's query:

```
CREATE VIEW view_with_a_renamed_column WITH (security_invoker = TRUE) AS
SELECT
    original_column_name AS custom_column_name
FROM `/domain/database/path/to/underlying_table`;
```

Asterisk (`*`) expansion in the view's query happens each time you read from the view. The list of columns returned by the following statement:

```
/*
CREATE VIEW view_with_an_asterisk WITH (security_invoker = TRUE) AS
SELECT
    *
FROM `/domain/database/path/to/underlying_table`;
*/

SELECT * FROM view_with_an_asterisk;
```

will change if the list of columns of the `underlying_table` is altered.

Examples

Create a view that will list only recent series from the `series` table:

```
CREATE VIEW recent_series WITH (security_invoker = TRUE) AS
SELECT
    *
FROM `/domain/database/path/to/series`
WHERE
    release_date > Date("2020-01-01");
```

Create a view that will list the titles of the first episodes of the recent series:

```
CREATE VIEW recent_series_first_episodes_titles WITH (security_invoker = TRUE) AS
SELECT
    episodes.title AS first_episode
FROM `/domain/database/path/to/recent_series`
    AS recent_series
JOIN `/domain/database/path/to/episodes`
    AS episodes
USING(series_id)
WHERE episodes.season_id = 1 AND episodes.episode_id = 1;
```

See also

- ALTER VIEW
- DROP VIEW

CREATE RESOURCE POOL

`CREATE RESOURCE POOL` creates a resource pool.

Syntax

```
CREATE RESOURCE POOL <name>
WITH ( <parameter_name> [= <parameter_value>] [, ... ] )
```

- `name` is the name of the resource pool being created. It must be unique. Path notation is not allowed (i.e., it must not contain `/`).
- `WITH ( <parameter_name> [= <parameter_value>] [, ... ] )` allows setting parameter values that define the behavior of the resource pool.

Parameters

- `CONCURRENT_QUERY_LIMIT` (Int32) — an optional field that sets the number of concurrently executing queries in the resource pool. If the value is `-1`, there is no limit. Default value: `-1`. Valid values: .
- `QUEUE_SIZE` (Int32) — an optional field that defines the size of the waiting queue. The system can hold no more than queries at a time. If the value is `-1`, there is no limit. Default value: `-1`. Valid values: .
- `DATABASE_LOAD_CPU_THRESHOLD` (Int32) — an optional field that sets the CPU load threshold for the entire database, after which queries are not sent for execution and remain in the queue. If the value is `-1`, there is no limit. Default value: `-1`. Valid values: .
- `TOTAL_MEMORY_LIMIT_PERCENT_PER_NODE` (Double) is an optional field that defines the percentage of available memory on the node that all queries in this resource pool can use. If the value is `-1`, there are no limits. Default value: `-1`. Valid values: .

  If a limit is set and the total memory consumption by queries in the pool reaches this limit:

  - New queries that require memory will fail with error `OVERLOADED`.
  - Already running queries that need additional memory will also fail with error `OVERLOADED`.
- `TOTAL_CPU_LIMIT_PERCENT_PER_NODE` (Double) — an optional field that sets the percentage of available CPU that all queries on the node in this resource pool can use. If the value is `-1`, there is no limit. Default value: `-1`. Valid values: .
- `QUERY_CPU_LIMIT_PERCENT_PER_NODE` (Double) — an optional field that defines the percentage of available CPU on the node for a single query in the resource pool. If the value is `-1`, there is no limit. Default value: `-1`. Valid values: .
- `RESOURCE_WEIGHT` (Int32) — an optional field that sets weights for distributing resources among pools. If the value is `-1`, weights are not used. Default value: `-1`. Valid values: .

> **Warning**
>
> The `QUERY_MEMORY_LIMIT_PERCENT_PER_NODE` parameter is currently not supported. To limit the amount of memory allocated to a resource pool, use the `TOTAL_MEMORY_LIMIT_PERCENT_PER_NODE` parameter.

Notes

Queries are always executed in some resource pool. By default, all queries are sent to the resource pool `default`, which is created automatically and cannot be deleted — it is always present in the system.

If the value of parameter `CONCURRENT_QUERY_LIMIT` is set to 0, then all queries sent to this pool will be immediately terminated with status `PRECONDITION_FAILED`.

Permissions

Requires permission `CREATE TABLE` on the directory `.metadata/workload_manager/pools`, an example of granting such permission:

```
GRANT 'CREATE TABLE' ON `.metadata/workload_manager/pools` TO `user1@domain`;
```

```
CREATE RESOURCE POOL olap WITH (
    CONCURRENT_QUERY_LIMIT=20,
    QUEUE_SIZE=1000,
    DATABASE_LOAD_CPU_THRESHOLD=80,
    RESOURCE_WEIGHT=100,
    TOTAL_MEMORY_LIMIT_PERCENT_PER_NODE=80,
    TOTAL_CPU_LIMIT_PERCENT_PER_NODE=70
)
```

In the example above, a resource pool is created with the following limits:

- Maximum number of concurrent queries — 20.
- Maximum queue size — 1000.
- When the database load reaches 80%, queries stop running concurrently.
- All queries in the pool can consume no more than 80% of the available memory on the node.
- The total limit on available CPU for all queries in the pool on the node is 70%.
- The resource pool has a weight of 100, which only takes effect in case of oversubscription.

- ALTER RESOURCE POOL
- DROP RESOURCE POOL

CREATE RESOURCE POOL CLASSIFIER

`CREATE RESOURCE POOL CLASSIFIER` creates a resource pool classifier.

Syntax

```
CREATE RESOURCE POOL CLASSIFIER <name>
WITH ( <parameter_name> [= <parameter_value>] [, ... ] )
```

- `name` ТАФ the name of the resource pool classifier being created. It must be unique. The name must not contain characters prohibited for schema objects.
- `WITH ( <parameter_name> [= <parameter_value>] [, ... ] )` ТАФ allows you to set parameter values that define the behavior of the resource pool classifier.

Common parameters

- `RANK` (Int64) ТАФ an optional field that specifies the selection order of the resource pool classifier. If the value is not specified, the maximum existing `RANK` is taken and 1000 is added to it. Valid values: a unique number in the range .
- `RESOURCE_POOL` (String) ТАФ the name of the resource pool to which requests matching the classifier's predicates are directed.
- `ACTION` (Enum) ТАФ the action applied to a request when the classifier matches. Allowed value ТАФ `reject`: the request is rejected, and the user receives an error of the form `Request is rejected by classifier '<name>' (rank=<rank>)`.

> **Note**
>
> The `RESOURCE_POOL` and `ACTION` parameters are mutually exclusive: exactly one of them must be specified in a classifier.

Predicate parameters

A predicate is a condition checked for an incoming request. A classifier matches if **all** of its predicates are satisfied (logical **AND**). To express **OR** logic, create multiple classifiers with different `RANK` values. Classifiers are processed in ascending order of `RANK`; processing stops at the first match ТАФ the request has that classifier's `ACTION` applied or is directed to its `RESOURCE_POOL`.

Predicate parameters are optional. A classifier without any predicates matches any request ТАФ this is useful for a "catch-all" classifier with the maximum `RANK`, for example, to direct all unclassified traffic to a specific pool (`RESOURCE_POOL`) or to reject it (`ACTION='reject'`).

> **Warning**
>
> Be careful when creating a "catch-all" classifier: all classifiers following it by `RANK` will never fire ТАФ processing stops at the first match, and the "catch-all" always matches.

List of predicates:

- `MEMBER_NAME` (String) ТАФ the SID of the user or group on whose behalf the request was made. See below for details.
- `HAS_PATH` (String) ТАФ path to a YDB object accessed by the request; supports wildcards `*` and `?`. See below for details.
- `HAS_APP_NAME` (String) ТАФ client application identifier. See below for details.
- `HAS_FULL_SCAN` (String) ТАФ path to an object for which a full scan is expected; supports wildcards `*` and `?`. See below for details.
- `HAS_STREAM` (Bool) ТАФ indicates whether the request is streaming. See below for details.

MEMBER_NAME

`MEMBER_NAME` is compared character by character with the user's SID or any group SID from their authentication token. The SID format depends on how the user logged into the system.

- **Built-in YDB users (login/password)** ТАФ the SID matches the username, without a suffix. For example, `user1`. For more information, see Authenticating by username and password.
- **Cloud users (Access Service)** ТАФ the SID has the form `<subject_id>@as`, where `<subject_id>` is the user ID in IAM. The suffix is set by the `access_service_domain` parameter (default `as`). For example, `ajeb89hv69nujke769fa@as`. For more information, see Authentication through a third-party IAM provider.
- **LDAP** ТАФ the SID has the form `<login>@<domain>`, where the domain is set by the `ldap_authentication_domain` parameter (default `ldap`). For example, `user1@ldap`. For more information, see LDAP directory integration.
- **External identity providers (OIDC)** ТАФ the SID has the form `<login>@<domain>`, where the domain is set by the `external_idp_authentication_domain` parameter in the authentication configuration (default `sso`). For example, `user1@sso`.

You can specify either the SID of a specific user or the SID of a group. The `all-users@well-known` group is automatically added to all authenticated users ТАФ it is convenient when you need to direct queries from all authenticated clients to a pool.

Example. Direct requests from user `user1@ldap` to the `olap` pool:

```
CREATE RESOURCE POOL CLASSIFIER cl_user WITH (
    RANK=100,
    RESOURCE_POOL='olap',
    MEMBER_NAME='user1@ldap'
);
```

HAS_PATH

`HAS_PATH` compares the paths of YDB objects accessed by the request against the specified mask. The mask supports wildcards: `*` ТАФ any sequence of characters, `?` ТАФ any single character. The predicate matches if at least one object in the request plan matches the mask.

Example. Direct requests to archive tables to the `pool_archive` pool:

```
CREATE RESOURCE POOL CLASSIFIER cl_archive WITH (
    RANK=700,
    RESOURCE_POOL='pool_archive',
    HAS_PATH='/Root/db/archive/*'
);
```

HAS_APP_NAME

`HAS_APP_NAME` compares the value against the client application identifier. The value is passed by the client in gRPC request metadata via the `x-ydb-application-name` header; YDB SDKs provide a way to set it on the client side. Comparison is exact match (no wildcards).

> **Warning**
>
> The `HAS_APP_NAME` value is set by the client and is not authenticated by the server тАФ do not use it as an access control mechanism. For effective isolation, combine it with `MEMBER_NAME` or direct unrecognized requests to a sandbox pool with strict limits.

Setting the application identifier on the client:

- **YDB UI** — fixed value `ydb-ui`, set by the viewer and not user-configurable.
- **YDB CLI** — not supported: the client application identifier is not sent in requests.
- **YDB C++ SDK** — per request via the `Header` parameter of `TRequestSettings`: `settings.Header({{ NYdb::YDB_APPLICATION_NAME, "my-app" }})`, where the `YDB_APPLICATION_NAME` constant equals `x-ydb-application-name`.
- **YDB Go SDK** — at the driver level via the `WithApplicationName` option in the `ydb.Open` call.
- **YDB Java SDK** — at the transport level via the `GrpcTransportBuilder.withApplicationName` method.
- **YDB Python SDK** — no dedicated parameter; the value is set per request via a generic header: `settings.with_header("x-ydb-application-name", "my-app")` (the `BaseRequestSettings.with_header` method).

Example. Direct requests from YDB UI to the `pool_adhoc` pool:

```
CREATE RESOURCE POOL CLASSIFIER cl_adhoc_ui WITH (
    RANK=200,
    RESOURCE_POOL='pool_adhoc',
    HAS_APP_NAME='ydb-ui'
);
```

HAS_FULL_SCAN

`HAS_FULL_SCAN` identifies requests that contain a full scan of the specified objects. A full scan is a table read without a key or key-range constraint. The argument is a path mask supporting wildcards `*` and `?`; the predicate matches if there is at least one such object in the request plan. Both row-oriented and column-oriented tables are supported. Objects to which the full-scan concept does not apply (for example, topics) are not considered.

Details of full-scan detection:

- **`LIMIT` does not cancel a full scan.** Without a key condition, the physical plan processes the entire table; `LIMIT` only limits the size of the result.
- **Secondary indexes.** A full scan of a secondary index's implementation table is counted against its own path. For example, for the table

  ```
  CREATE TABLE orders (
      Id Uint64 NOT NULL,
      Status Utf8,
      PRIMARY KEY (Id),
      INDEX by_status GLOBAL ON (Status)
  );
  ```

  the index table has path `/Root/orders/by_status/indexImplTable`. The query `SELECT * FROM orders VIEW by_status` performs a full scan of the index table тАФ the main `/Root/orders` is not scanned. Therefore:

  - `HAS_FULL_SCAN='/Root/orders'` тАФ **will not match**;
  - `HAS_FULL_SCAN='/Root/orders/by_status/indexImplTable'` or `HAS_FULL_SCAN='/Root/orders/*'` тАФ **will match**.

Example. Reject requests that cause a full scan of the orders archive:

```
CREATE RESOURCE POOL CLASSIFIER cl_fullscan_reject WITH (
    RANK=100,
    ACTION='reject',
    HAS_FULL_SCAN='/Root/db/orders_archive/*'
);
```

HAS_STREAM

`HAS_STREAM` determines whether a request is streaming тАФ that is, performs a long-running continuous read and/or write over data streams. Allowed values:

- `true` тАФ the classifier matches streaming requests;
- `false` тАФ the classifier matches non-streaming requests.

Example. Direct streaming requests to the `pool_stream` pool:

```
CREATE RESOURCE POOL CLASSIFIER cl_stream WITH (
    RANK=500,
    RESOURCE_POOL='pool_stream',
    HAS_STREAM=true
);
```

Notes

If `RANK` is not specified in the DDL for creating a resource pool classifier, it will be assigned the default value . All `RANK` values must be unique to ensure a strictly deterministic order of resource pool selection in case of conflicting conditions. This behavior is chosen to allow adding new resource pool classifiers between existing ones.

It is also possible to have a classifier that references a non-existent resource pool or one to which the user does not have access. In that case, it is skipped.

For limitations on the number of classifiers, see the limitations page.

Permissions

The permission `USE` on the database is required.

Example of granting such a permission:

```
GRANT 'USE' ON `/my_db` TO `user1@domain`;
```

Examples

Below is a combined example that composes several classifiers and predicates: rejecting full scans of archive tables, isolating streaming requests, and dedicating a pool for interactive admin queries from YDB UI.

Creating resource pools:

```
CREATE RESOURCE POOL pool_stream WITH (
    TOTAL_CPU_LIMIT_PERCENT_PER_NODE=20
);

CREATE RESOURCE POOL pool_adhoc_admin WITH (
    TOTAL_CPU_LIMIT_PERCENT_PER_NODE=10
);
```

Creating classifiers:

```
-- Reject full scans of archive tables.
CREATE RESOURCE POOL CLASSIFIER cl_fullscan_reject WITH (
    RANK=100,
    ACTION='reject',
    HAS_FULL_SCAN='/Root/db/orders_archive/*'
);

-- Direct streaming requests to a dedicated pool.
CREATE RESOURCE POOL CLASSIFIER cl_stream WITH (
    RANK=200,
    RESOURCE_POOL='pool_stream',
    HAS_STREAM=true
);

-- Admin requests from YDB UI — into the interactive-queries pool.
-- AND condition: both MEMBER_NAME and HAS_APP_NAME must match.
CREATE RESOURCE POOL CLASSIFIER cl_adhoc_admin WITH (
    RANK=300,
    RESOURCE_POOL='pool_adhoc_admin',
    MEMBER_NAME='admin',
    HAS_APP_NAME='ydb-ui'
);
```

Classifiers are processed in ascending order of `RANK`; the first matching classifier is applied to the request. A request that does not match any classifier is directed to the `default` pool.

See also

- Workload Manager — resource consumption management
- ALTER RESOURCE POOL CLASSIFIER
- DROP RESOURCE POOL CLASSIFIER

CREATE TOPIC

The `CREATE TOPIC` call creates a topic.

When creating a topic, you can add topic consumers to it and topic settings.

```
CREATE TOPIC topic_path (
    CONSUMER consumer1,
    CONSUMER consumer2 WITH (setting1 = value1)
) WITH (
    topic_setting2 = value2
);
```

All the parameters except the topic name are optional. By default, a topic is created without consumers. All the omitted settings are also set by default (both for the topic and its consumers).

> **Note**
>
> When choosing a name for the topic, please consider the common schema objects naming rules

Examples

Creating a topic without consumers with default settings:

```
CREATE TOPIC `my_topic`;
```

Creating a topic with a single consumer and the important option enabled:

```
CREATE TOPIC `my_topic` (
    CONSUMER my_consumer WITH (important = true)
);
```

Full list of available topic consumer settings

- `important`: Defines an important consumer. No data will be deleted from the topic until all the important consumers read them. Value type: `boolean`, default value: `false`.
- `read_from`: Sets up the message write time starting from which the consumer will receive data. Data written before this time will not be read. Value type: `Datetime` OR `Timestamp` OR `integer` (unix-timestamp in the numeric format). Default value: `0` (read from the earliest available message).
- `supported_codecs`: List of codecs supported by the consumer.

Creating a topic with the retention period of one day:

```
CREATE TOPIC `my_topic` WITH(
    retention_period = Interval('P1D')
);
```

Full list of available topic settings

- `min_active_partitions`: Minimum number of topic partitions. During automatic load balancing, the number of active partitions will not decrease below this value. Value type: `integer`, default value: `1`.
- `partition_count_limit`: Maximum number of active partitions in the topic. `0` is interpreted as unlimited. Value type: `integer`, default value: `0`.
- `retention_period`: Data retention period in the topic. Value type: `Interval`, default value: `24h`.
- `retention_storage_mb`: Limit on the maximum disk space occupied by the topic data. When this value is exceeded, the older data is cleared, like under a retention policy. The consumed space may exceed the set value when autopartitioning is enabled. Value type: `integer`, default value: `0` (no limit).
- `partition_write_speed_bytes_per_second`: Maximum allowed write speed per partition. If a write speed for a given partition exceeds this value, the write speed will be capped. Value type: `integer`, default value: `2097152` (2MB).
- `partition_write_burst_bytes`: Write quota allocated for write bursts. When set to zero, the actual write_burst value is equalled to the quota value (this allows write bursts of up to one second). Value type: `integer`, default value: `0`.
- `metering_mode`: Resource metering mode (`RESERVED_CAPACITY` - based on the allocated resources or `REQUEST_UNITS` - based on actual usage). This option applies to topics in serverless databases. Value type: `String`.
- `supported_codecs`: List of codecs supported by the topic. Value type: `String`.

CREATE USER

Creates a user with the specified name and password.

Syntax:

```
CREATE USER user_name [option]
```

- `user_name`: The name of the user. It may contain lowercase Latin letters and digits.
- `option` — command option:
  - `PASSWORD 'password'` — creates a user with the password `password`.
  - `PASSWORD NULL` — creates a user with an empty password (default).
  - `NOLOGIN` - disallows user login (user lockout).
  - `LOGIN` - allows user login (default).

> **Note**
>
> The scope of the commands `CREATE USER`, `ALTER USER`, and `DROP USER` does not extend to external user directories. Keep this in mind if users with third-party authentication (e.g., LDAP) are connecting to YDB. For example, the `CREATE USER` command does not create a user in the LDAP directory. Learn more about YDB's interaction with the LDAP directory.

COMMIT

By default, the entire YQL query is executed within a single transaction, and independent parts inside it are executed in parallel, if possible.
Using the `COMMIT;` keyword you can add a barrier to the execution process to delay execution of expressions that follow until all the preceding expressions have completed.

To commit in the same way automatically after each expression in the query, you can use `PRAGMA autocommit;`.

Examples

```
INSERT INTO result1 SELECT * FROM my_table;
INSERT INTO result2 SELECT * FROM my_table;
COMMIT;
-- result2 will already include the SELECT contents from the second line:
INSERT INTO result3 SELECT * FROM result2;
```

DECLARE

Declares a typed named expression whose value will be passed separately from the query text. With parameterization, you can separately develop an analytical solution and then launch it sequentially with different input values.

In the case of transactional load, parameters let you avoid recompilation of queries when repeating calls of the same type. This way you can reduce server utilization and exclude compilation time from the total time of query execution.

Passing of parameters is supported in the SDK, CLI, and graphical interfaces.

Syntax

```
DECLARE $named-node AS data_type;
```

1. `DECLARE` keyword.
2. `$named-node`: The name by which you can access the passed value. It must start with `$`.
3. `AS` keyword.
4. `data_type` is the data type represented as a string in the accepted format.

Only serializable data types are allowed:

- Primitive types.
- Optional types.
- Containers, except `Stream<Type>`.
- `Void` and `Null` are the supported special types.

Example

```
DECLARE $x AS String;
DECLARE $y AS String?;
DECLARE $z AS List<String>;

SELECT $x, $y, $z;
```

DELETE FROM

> **Warning**
>
> Currently, mixing column-oriented tables and row-oriented tables in a single transaction is supported only if the transaction performs read operations; no writes are allowed. Support for read-write transactions involving both table types is under development.
>
> If a write transaction includes both types of tables, it fails with the following error: `Write transactions that use both row-oriented and column-oriented tables are disabled at current time`.

Deletes rows that match the `WHERE` clause, from the table.

Example

```
DELETE FROM my_table
WHERE Key1 == 1 AND Key2 >= "One";
```

DELETE FROM ... ON

Deletes rows based on the results of a subquery. The set of columns returned by the subquery must be a subset of the table's columns being updated, and all columns of the table's primary key must be present in the returned columns. The data types of the columns returned by the subquery must match the data types of the corresponding columns in the table.

The primary key value is used to search for rows to be deleted from the table. The presence of other (non-key) columns of the table in the output of the subquery does not affect the results of the deletion operation.

Example

```
$to_delete = (
    SELECT Key, SubKey FROM my_table WHERE Value = "ToDelete" LIMIT 100
);

DELETE FROM my_table ON
SELECT * FROM $to_delete;
```

DELETE FROM ... RETURNING

Deletes rows and returns their values in a single operation. It allows to retrieve data from the rows being deleted without needing to perform a separate SELECT query beforehand.

Examples

- Return all values of modified rows

```
DELETE FROM orders
WHERE status = 'cancelled'
RETURNING *;
```

- Return specific columns

```
DELETE FROM orders
WHERE status = 'cancelled'
RETURNING order_id, order_date;
```

See also

- BATCH DELETE

DISCARD

Calculates `SELECT` without returning the result neither to the client or table.

It's good to combine it with `Ensure` to check the final calculation result against the user's criteria.

A query with `DISCARD` is executed in full — with all its filters, aggregations, and `Ensure` checks — but the result set is not returned to the client. The data is not sent over the network either: the client receives only the query execution status. For large outputs, this saves a noticeable amount of traffic and memory.

In a query consisting of multiple statements, `DISCARD` applies to an individual statement:

```
SELECT 1;          -- returned
DISCARD SELECT 2;  -- executed, but not included in the response
SELECT 3;          -- returned
```

The client will receive two result sets — from the first and third statements.

`DISCARD` applies only to a statement as a whole and cannot be used inside expressions. In particular, it is not allowed:

- in subqueries — `SELECT * FROM (DISCARD SELECT 1)`;
- in `WHERE ... IN (...)` — `SELECT * FROM my_table WHERE Key IN (DISCARD SELECT 1)`;
- in `UNION ALL` operands — `SELECT 1 UNION ALL DISCARD SELECT 2`.

Note

`DISCARD` is supported for queries executed via the Query Service starting from YDB version 26.2. When a query is executed via the legacy interfaces (Table Service, scan queries), `DISCARD` is ignored and the result is returned to the client — this behavior is preserved for backward compatibility.

Examples

```
DISCARD SELECT 1;
```

```
DISCARD SELECT Ensure(
    Data,
    Data < 1000000,
    "Value too big"
) FROM `result_table`;
```

If the `Ensure` condition is violated, the query fails with an error. Otherwise, the query completes successfully, and the client does not receive the result set that would otherwise have to be downloaded in full.

DROP ASYNC REPLICATION

The `DROP ASYNC REPLICATION` statement deletes an asynchronous replication instance. When an asynchronous replication instance is deleted, the following objects are also deleted:

- automatically created streams of changes
- replicas (optionally)

Syntax

```
DROP ASYNC REPLICATION <name> [CASCADE]
```

Parameters

- `name` — the name of the asynchronous replication instance.
- `CASCADE` — cascaded deletion of the replicas that were created for a given asynchronous replication instance.

Examples

This section contains examples of YQL statements that drop the asynchronous replication instance created with the following expression:

```
CREATE ASYNC REPLICATION my_replication
FOR original_table AS replica_table
WITH (
    CONNECTION_STRING = 'grpcs://example.com:2135/?database=/Root/another_database',
    TOKEN_SECRET_PATH = 'my_secret'
);
```

The following statement drops an asynchronous replication instance and the automatically created stream of changes for the `original_table` table, but the `replica_table` table is not deleted:

```
DROP ASYNC REPLICATION my_replication;
```

The following statement drops an asynchronous replication instance, the automatically created stream of changes for the `original_table` table, and the `replica_table` table:

```
DROP ASYNC REPLICATION my_replication CASCADE;
```

See also

- CREATE ASYNC REPLICATION
- ALTER ASYNC REPLICATION

DROP BACKUP COLLECTION

The `DROP BACKUP COLLECTION` statement deletes a backup collection and all its backups.

```
DROP BACKUP COLLECTION collection_name;
```

Parameters

- `collection_name` — name of the backup collection to drop.

> **Warning**
>
> This operation permanently deletes the backup collection and all backups it contains from the cluster. This action cannot be undone.

> **Note**
>
> Dropping a backup collection only affects cluster-stored data. Any backups previously exported to external storage (S3 or filesystem) are not affected and remain available for import.

Examples

Dropping a backup collection:

```
DROP BACKUP COLLECTION old_backups;
```

See also

- Backup collections.
- CREATE BACKUP COLLECTION.
- BACKUP.
- RESTORE.

DROP GROUP

Deletes the specified group. You can list multiple groups under one operator.

Syntax:

```
DROP GROUP [ IF EXISTS ] group_name [, ...]
```

- `IF EXISTS`: Suppress an error if the group doesn't exist.
- `group_name`: The name of the group to be deleted.

DROP EXTERNAL DATA SOURCE

Deletes the specified external data source.

If no external data source with that name exists, an error is returned.

Example

```
DROP EXTERNAL DATA SOURCE my_external_data_source;
```

DROP EXTERNAL TABLE

Deletes the specified external table.

If no external table with that name exists, an error is returned.

Example

```
DROP EXTERNAL TABLE my_table;
```

DROP STREAMING QUERY

`DROP STREAMING QUERY` deletes a streaming query.

Syntax

```
DROP STREAMING QUERY [IF EXISTS] <query_name>
```

Parameters

- `IF EXISTS` — do not fail if the streaming query does not exist.
- `query_name` — name of the streaming query to delete.

Permissions

Requires permission `REMOVE SCHEMA` on the streaming query. Example grant for `my_streaming_query`:

```
GRANT REMOVE SCHEMA ON my_streaming_query TO `user@domain`
```

Examples

Delete `my_streaming_query`:

```
DROP STREAMING QUERY my_streaming_query
```

See also

- Streaming queries
- CREATE STREAMING QUERY
- ALTER STREAMING QUERY

DROP OBJECT (TYPE SECRET)

> **Alert**
>
> **This command is deprecated** and will be removed in future versions of YDB. The recommended syntax for working with secrets is described in the Secrets section.

Deletes the specified secret.

If no secret with that name exists, an error is returned.

Example

```
DROP OBJECT my_secret (TYPE SECRET);
```

DROP OBJECT (TYPE SECRET_ACCESS)

> **Alert**
>
> **This command is deprecated** and will be removed in future versions of YDB. The recommended syntax for working with secrets is described in the Secrets section.

Deletes the specified access rule for a secret.

If no rule with that name exists, an error is returned.

Example

```
DROP OBJECT (TYPE SECRET_ACCESS) `MySecretName:another_user`;
```

DROP TABLE

Deletes the specified table.

If there is no such table, an error is returned.

Examples

```
DROP TABLE my_table;
```

DROP SECRET

The `DROP SECRET` statement deletes an existing secret.

Syntax

```
DROP SECRET secret_name
```

- `secret_name` — the name of the secret to delete.

Permissions

Deleting a secret requires the rights `REMOVE SCHEMA` and `ALTER SCHEMA`.

Examples

Delete the secret named `secret_name`:

```
DROP SECRET secret_name;
```

See also

- CREATE SECRET
- ALTER SECRET

DROP TRANSFER

The `DROP TRANSFER` statement deletes a transfer instance. If a consumer was created automatically when the transfer was created, it is also deleted. The system will keep trying to delete the consumer until the operation is successful.

The `DROP TRANSFER` statement does not delete the destination table or the source topic.

Syntax

```
DROP TRANSFER <name>
```

where:

- `name` — the name of the transfer instance.

Permissions

The following permissions are required to delete a transfer:

- `REMOVE SCHEMA` — to delete the transfer instance;
- `ALTER SCHEMA` — to delete the automatically created topic consumer (if applicable).

Examples

The following query deletes the transfer named `my_transfer`:

```
DROP TRANSFER my_transfer;
```

See Also

- CREATE TRANSFER
- ALTER TRANSFER
- Data transfer

DROP TOPIC

`DROP TOPIC` deletes the specified topic.

Syntax

```
DROP TOPIC <topic_path>;
```

Examples

The following command will delete the topic named `my_topic`:

```
DROP TOPIC my_topic;
```

See also

- CREATE TOPIC
- ALTER TOPIC

DROP VIEW

`DROP VIEW` deletes an existing view.

Syntax

```
DROP VIEW [IF EXISTS] <name>
```

Parameters

- `IF EXISTS` - when specified, the statement does not return an error if a view with the given name does not exist.
- `name` - the name of the view to be deleted.

Examples

The following command will drop the view named `recent_series`:

```
DROP VIEW recent_series;
```

See also

- CREATE VIEW
- ALTER VIEW

DROP RESOURCE POOL

`DROP RESOURCE POOL` removes a resource pool.

Syntax

```
DROP RESOURCE POOL <name>
```

Parameters

- `name` — name of the resource pool to drop.

Permissions

The `REMOVE SCHEMA` permission on the pool under `.metadata/workload_manager/pools` is required. Example:

```
GRANT 'REMOVE SCHEMA' ON `.metadata/workload_manager/pools` TO `user1@domain`;
```

Examples

The following removes the resource pool named `olap`:

```
DROP RESOURCE POOL olap;
```

See also

- Workload Manager — resource consumption management
- CREATE RESOURCE POOL
- ALTER RESOURCE POOL

DROP RESOURCE POOL CLASSIFIER

`DROP RESOURCE POOL CLASSIFIER` removes a resource pool classifier.

Syntax

```
DROP RESOURCE POOL CLASSIFIER <name>
```

Parameters

- `name` — name of the resource pool classifier to drop.

Permissions

The `ALL` permission on the database is required. Example:

```
GRANT 'ALL' ON `/my_db` TO `user1@domain`;
```

Examples

The following removes the classifier named `olap_classifier`:

```
DROP RESOURCE POOL CLASSIFIER olap_classifier;
```

See also

- Workload Manager — resource consumption management
- CREATE RESOURCE POOL CLASSIFIER
- ALTER RESOURCE POOL CLASSIFIER

DROP USER

Deletes the specified user. You can list multiple users under one operator.

Syntax:

```
DROP USER [ IF EXISTS ] user_name [, ...]
```

- `IF EXISTS` : Suppress an error if the user doesn't exist.
- `user_name` : The name of the user to be deleted. It also supports the ability to set a comma-separated list of users, for example: `DROP USER user1, user2, user3;`

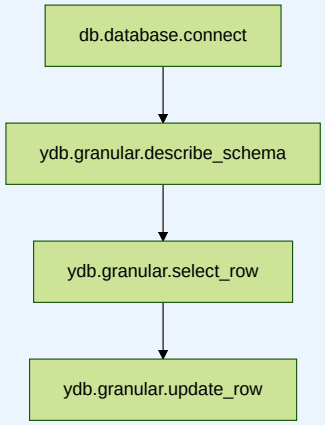
GRANT

The `GRANT` command allows setting access rights to schema objects for a user or group of users.

Syntax:

```
GRANT {{permission_name} [, ...] | ALL [PRIVILEGES]} ON {path_to_scheme_object [, ...]} TO {role_name [,
...]} [WITH GRANT OPTION]
```

- `permission_name` - the name of the access right to schema objects that needs to be assigned.
- `path_to_scheme_object` - the path to the schema object to which rights are granted.
- `role_name` - the name of the user or group for which rights to the schema object are granted.



`WITH GRANT OPTION` - using this clause gives the user or group the right to manage access rights - to grant or revoke specific rights. The clause functions similarly to granting the `"ydb.access.grant"` right or `GRANT`.
A subject with the `ydb.access.grant` right cannot grant rights broader than they themselves have on the access object `path_to_scheme_object`.

Access rights

As names of access rights, you can use either the names of YDB rights or the corresponding YQL keywords.
The possible names of rights are listed in the table below.

YDB right	YQL keyword	Description
Database-level rights		
`ydb.database.connect`	`CONNECT`	The right to connect to a database
`ydb.database.create`	`CREATE`	The right to create new databases in the cluster
`ydb.database.drop`	`DROP`	The right to delete databases in the cluster
Elementary rights for database objects		
`ydb.granular.select_row`	`SELECT ROW`	The right to read rows from a table (select), read messages from topics, use secret values
`ydb.granular.update_row`	`UPDATE ROW`	The right to update rows in a table (insert, update, upsert, replace), write messages to topics
`ydb.granular.erase_row`	`ERASE ROW`	The right to delete rows from a table (delete)
`ydb.granular.create_directory`	`CREATE DIRECTORY`	The right to create and delete directories, including existing and nested ones
`ydb.granular.create_table`	`CREATE TABLE`	The right to create tables (including index, external, columnar), views, sequences
`ydb.granular.create_queue`	`CREATE QUEUE`	The right to create topics
`ydb.granular.remove_schema`	`REMOVE SCHEMA`	The right to delete objects (directories, tables, topics) that were created using rights
`ydb.granular.describe_schema`	`DESCRIBE SCHEMA`	The right to view existing access rights (ACL) on an access object, view descriptions of access objects (directories, tables, topics)
`ydb.granular.alter_schema`	`ALTER SCHEMA`	The right to modify access objects (directories, tables, topics), including users' rights to access objects
Additional flags		
`ydb.access.grant`	`GRANT`	The right to grant or revoke rights from other users to the extent not exceeding the current scope of the user's rights on the access object
`ydb.tables.modify`	`MODIFY TABLES`	`ydb.granular.update_row` + `ydb.granular.erase_row`
`ydb.tables.read`	`SELECT TABLES`	Alias for `ydb.granular.select_row`
`ydb.generic.list`	`LIST`	Alias for `ydb.granular.describe_schema`
`ydb.generic.read`	`SELECT`	`ydb.granular.select_row` + `ydb.generic.list`
`ydb.generic.write`	`INSERT`	`ydb.granular.update_row` + `ydb.granular.erase_row` + `ydb.granular.create_directory` + `ydb.granular.create_table` + `ydb.granular.create_queue` + `ydb.granular.remove_schema` + `ydb.granular.alter_schema`
`ydb.generic.use_legacy`	`USE LEGACY`	`ydb.generic.read` + `ydb.generic.write` + `ydb.access.grant`
`ydb.generic.use`	`USE`	`ydb.generic.use_legacy` + `ydb.database.connect`
`ydb.generic.manage`	`MANAGE`	`ydb.database.create` + `ydb.database.drop`
`ydb.generic.full_legacy`	`FULL LEGACY`	`ydb.generic.use_legacy` + `ydb.generic.manage`
`ydb.generic.full`	`FULL`	`ydb.generic.use` + `ydb.generic.manage`

- `ALL [PRIVILEGES]` is used to specify all possible rights on schema objects for users or groups. `PRIVILEGES` is an optional keyword needed for compatibility with the SQL standard.

> **Note**
>
> Rights `ydb.database.connect`, `ydb.granular.describe_schema`, `ydb.granular.select_row`, and `ydb.granular.update_row` should be considered as layers of rights.
>
> 
>
>
> For example, to update rows, you need not only the right `ydb.granular.update_row`, but also all the overlying rights.

Examples

- Assign the `ydb.generic.read` right to the table `/shop_db/orders` for the user `user1`:

```
GRANT 'ydb.generic.read' ON `/shop_db/orders` TO user1;
```

  The same command, using the keyword:

```
GRANT SELECT ON `/shop_db/orders` TO user1;
```

- Assign the rights `ydb.database.connect` and `ydb.generic.list` to the root of the database `/shop_db` for user `user2` and group `group1`:

```
GRANT LIST, CONNECT ON `/shop_db` TO user2, group1;
```

- Assign the `ydb.generic.use` right to the tables `/shop_db/orders` and `/shop_db/sellers` for users `user1@domain` and `user2@domain`:

```
GRANT 'ydb.generic.use' ON `/shop_db/orders`, `/shop_db/sellers` TO `user1@domain`, `user2@domain`;
```

- Grant all rights to the table `/shop_db/sellers` for the user `admin_user`:

```
GRANT ALL ON `/shop_db/sellers` TO admin_user;
```

INSERT INTO

> **Warning**
>
> Currently, mixing column-oriented tables and row-oriented tables in a single transaction is supported only if the transaction performs read operations; no writes are allowed. Support for read-write transactions involving both table types is under development.
>
> If a write transaction includes both types of tables, it fails with the following error: `Write transactions that use both row-oriented and column-oriented tables are disabled at current time`.

Adds rows to the table. If you try to insert a row into a table with an existing primary key value, the operation fails with the `PRECONDITION_FAILED` error code and the `Operation aborted due to constraint violation: insert_pk` message returned.

`INSERT INTO` lets you perform the following operations:

- Adding constant values using `VALUES`.

```
INSERT INTO my_table (Key1, Key2, Value1, Value2)
VALUES (345987,'ydb', 'Pied piper', 1414);
COMMIT;
```

```
INSERT INTO my_table (key, value)
VALUES ("foo", 1), ("bar", 2);
```

- Saving the `SELECT` result.

```
INSERT INTO my_table
SELECT Key AS Key1, "Empty" AS Key2, Value AS Value1
FROM my_table1;
```

When working with external file data sources, you can specify additional parameters:

- `FORMAT` — stored data format in file storage for federated queries. Allowed values: `csv_with_names`, `tsv_with_names`, `json_list`, `json_each_row`, `json_as_string`, `parquet`, `raw`.
- `COMPRESSION` — file compression in file storage for federated queries. Allowed values: gzip, zstd, lz4, brotli, bzip2, xz.
- `PARTITIONED_BY` — list of partition columns for data in file storage in federated queries. Lists columns in the order they appear in the file layout.
- `projection.enabled` — flag to enable extended data partitioning. Allowed values: `true`, `false`.
- `projection.<field_name>.type` — field type for extended data partitioning. Allowed values: `integer`, `enum`, `date`.
- `projection.<field_name>.<options>` — extended properties of a field for extended data partitioning.

Example

```
INSERT INTO `connection`.`test/`
WITH
(
  FORMAT = "csv_with_names"
)
SELECT
    "value" AS value, "name" AS name
```

Where:

- `connection` — name of the connection to S3 (Yandex Object Storage).
- `test/` — path inside the bucket where data is written. Files are created with random names.

INSERT INTO ... RETURNING

Inserts rows and returns their values in a single operation. It allows to retrieve data from the rows being inserted without needing to perform a separate SELECT query afterwards.

Examples

- Return all values of modified rows

```
INSERT INTO some_table (id, year, color, price)
VALUES (1103, 2023, 'blue', 400)
RETURNING *;
```

- Return specific columns

```
INSERT INTO some_table (id, color, price)
VALUES
    (1101, 'red', 200),
    (1102, 'green', 300)
RETURNING id, price;
```

INTO RESULT

Lets you set a custom label for SELECT.

Examples

```
SELECT 1 INTO RESULT foo;
```

```
SELECT * FROM
my_table
WHERE value % 2 == 0
INTO RESULT `Result name`;
```

PRAGMA

Definition

Redefinition of settings.

Syntax

`PRAGMA x.y = "z";` or `PRAGMA x.y("z", "z2", "z3");`:

- `x`: (optional) The category of the setting.
- `y`: The name of the setting.
- `z`: (optional for flags) The value of the setting. The following suffixes are acceptable:
  - `Kb`, `Mb`, `Gb`: For the data amounts.
  - `sec`, `min`, `h`, `d`: For the time values.

Examples

```
PRAGMA AutoCommit;
```

```
PRAGMA TablePathPrefix = "home/yql";
```

```
PRAGMA Warning("disable", "1101");
```

With some exceptions, you can return the settings values to their default states using `PRAGMA my_pragma = default;`.

For the full list of available settings, see the table below.

Scope

Unless otherwise specified, a pragma affects all the subsequent expressions up to the end of the module where it's used. If necessary and logically possible, you can change the value of this setting several times within a given query to make it different at different execution steps.

There are also special scoped pragmas with the scope defined by the same rules as the scope of named expressions. Unlike scoped pragmas, regular pragmas can only be used in the global scope (not inside lambda functions, `ACTION`, etc.).

Global

AutoCommit

Value type	Default
Flag	false

Automatically run COMMIT after every statement.

TablePathPrefix

Value type	Default
String	—

Add the specified prefix to the cluster table paths. It uses standard file system path concatenation, supporting parent folder `..` referencing and requiring no trailing slash. For example,

`PRAGMA TablePathPrefix = "home/yql"; SELECT * FROM test;`

The prefix is not added if the table name is an absolute path (starts with /).

UseTablePrefixForEach

Value type	Default
Flag	false

EACH uses TablePathPrefix for each list item.

Warning

Value type	Default
1. Action 2. Warning code or "*"	—

Action:

- `disable`: Disable.
- `error`: Treat as an error.
- `default`: Revert to the default behavior.

The warning code is returned with the text itself (it's displayed on the right side of the web interface).

Example

```
PRAGMA Warning("error", "*");
PRAGMA Warning("disable", "1101");
PRAGMA Warning("default", "4503");
```

In this case, all the warnings are treated as errors, except for the warning `1101` (that will be disabled) and `4503` (that will be processed by default, that is, remain a warning). Since warnings may be added in new YQL releases, use `PRAGMA Warning("error", "*");` with caution (at least cover such queries with autotests).

SimpleColumns

`SimpleColumns` / `DisableSimpleColumns`

Value type	Default
Flag	true

When you use `SELECT foo.* FROM ... AS foo`, remove the `foo.` prefix from the names of the result columns.

It can be also used with a JOIN, but in this case it may fail in the case of a name conflict (that can be resolved by using WITHOUT and renaming columns). For JOIN in SimpleColumns mode, an implicit Coalesce is applied to the key columns.

CoalesceJoinKeysOnQualifiedAll

`CoalesceJoinKeysOnQualifiedAll` / `DisableCoalesceJoinKeysOnQualifiedAll`

Value type	Default
Flag	true

Controls implicit Coalesce for the key `JOIN` columns in the SimpleColumns mode. If the flag is set, the Coalesce is made for key columns if there is at least one expression in the format `foo.*` or `*` in SELECT: for example, `SELECT a.* FROM T1 AS a JOIN T2 AS b USING(key)`. If the flag is not set, then Coalesce for JOIN keys is made only if there is an asterisk '*' after `SELECT`

StrictJoinKeyTypes

`StrictJoinKeyTypes` / `DisableStrictJoinKeyTypes`

Value type	Default
Flag	false

If the flag is set, then JOIN will require strict matching of key types.
By default, JOIN preconverts keys to a shared type, which might result in performance degradation.
StrictJoinKeyTypes is a scoped setting.

AnsiInForEmptyOrNullableItemsCollections

Value type	Default
Flag	false

This pragma brings the behavior of the `IN` operator in accordance with the standard when there's `NULL` in the left or right side of `IN`. The behavior of `IN` when on the right side there is a Tuple with elements of different types also changed. Examples:

```
1 IN (2, 3, NULL) = NULL (was Just(False))
NULL IN () = Just(False) (was NULL)
(1, null) IN ((2, 2), (3, 3)) = Just(False) (was NULL)
```

For more information about the `IN` behavior when operands include `NULL`s, see here. You can explicitly select the old behavior by specifying the pragma `DisableAnsiInForEmptyOrNullableItemsCollections`. If no pragma is set, then a warning is issued and the old version works.

AnsiRankForNullableKeys

Value type	Default
Flag	false

Aligns the RANK/DENSE_RANK behavior with the standard if there are optional types in the window sort keys or in the argument of such window functions. It means that:

- The result type is always Uint64 rather than Uint64?.
- NULLs in keys are treated as equal to each other (the current implementation returns NULL).

You can explicitly select the old behavior by using the `DisableAnsiRankForNullableKeys` pragma. If no pragma is set, then a warning is issued and the old version works.

AnsiCurrentRow

Value type	Default
Flag	false

Aligns the implicit setting of a window frame with the standard if there is ORDER BY.
If AnsiCurrentRow is not set, then the `(ORDER BY key)` window is equivalent to `(ORDER BY key ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)`.
The standard also requires that this window behave as `(ORDER BY key RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)`.

The difference is in how `CURRENT ROW` is interpreted. In `ROWS` mode `CURRENT ROW` is interpreted literally: the current row in a partition.
In `RANGE` mode, the end of the `CURRENT ROW` frame means "the last row in a partition with a sort key equal to the current row".

AnsiOrderByLimitInUnionAll

Value type	Default
Flag	false

Aligns the UNION ALL behavior with the standard if there is `ORDER BY/LIMIT/DISCARD/INSERT INTO` in the combined subqueries. It means that:

- `ORDER BY/LIMIT/INSERT INTO` are allowed only after the last subquery.
- `DISCARD` is allowed only before the first subquery.
- The specified operators apply to the `UNION ALL` result (unlike the current behavior when they apply only to the subquery).
- To apply an operator to a subquery, enclose the subquery in parentheses.

You can explicitly select the old behavior by using the `DisableAnsiOrderByLimitInUnionAll` pragma. If no pragma is set, then a warning is issued and the old version works.

OrderedColumns

`OrderedColumns` / `DisableOrderedColumns`

Output the column order in SELECT/JOIN/UNION ALL and preserve it when writing the results. The order of columns is undefined by default.

PositionalUnionAll

Enable the standard column-by-column execution for UNION ALL. This automatically enables ordered columns.

RegexUseRe2

Value type	Default
Flag	false

Use Re2 UDF instead of Pcre to execute SQL the `REGEX`, `MATCH`, `RLIKE` statements. Re2 UDF can properly handle Unicode characters, unlike the default Pcre UDF.

ClassicDivision

Value type	Default
Flag	true

In the classical version, the result of integer division remains integer (by default).
If disabled, the result is always Double.
ClassicDivision is a scoped setting.

UnicodeLiterals

`UnicodeLiterals` / `DisableUnicodeLiterals`

Value type	Default
Flag	false

When this mode is enabled, string literals without suffixes like "foo"/'bar'/@@multiline@@ will be of type `Utf8`, when disabled - `String`.
UnicodeLiterals is a scoped setting.

WarnUntypedStringLiterals

`WarnUntypedStringLiterals` / `DisableWarnUntypedStringLiterals`

Value type	Default
Flag	false

When this mode is enabled, a warning will be generated for string literals without suffixes like "foo"/'bar'/@@multiline@@. It can be suppressed by explicitly choosing the suffix `s` for the `String` type, or `u` for the `Utf8` type.
WarnUntypedStringLiterals is a scoped setting.

AllowDotInAlias

Value type	Default
Flag	false

Enable dot in names of result columns. This behavior is disabled by default, since the further use of such columns in JOIN is not fully implemented.

WarnUnnamedColumns

Value type	Default

Flag	false

Generate a warning if a column name was automatically generated for an unnamed expression in `SELECT` (in the format `column[0-9]+`).

GroupByLimit

Value type	Default
Positive number	32

Increasing the limit on the number of dimensions in GROUP BY.

GroupByCubeLimit

Value type	Default
Positive number	5

Increasing the limit on the number of dimensions in GROUP BY.

Use this option with care, because the computational complexity of the query grows exponentially with the number of dimensions.

Yson

Managing the default behavior of Yson UDF, for more information, see the documentation and, in particular, Yson::Options.

`yson.AutoConvert`

Value type	Default
Flag	false

Automatic conversion of values to the required data type in all Yson UDF calls, including implicit calls.

`yson.Strict`

Value type	Default
Flag	true

Strict mode control in all Yson UDF calls, including implicit calls. If the value is omitted or is `"true"`, it enables the strict mode. If the value is `"false"`, it disables the strict mode.

`yson.DisableStrict`

Value type	Default
Flag	false

An inverted version of `yson.Strict`. If the value is omitted or is `"true"`, it disables the strict mode. If the value is `"false"`, it enables the strict mode.

YDB

`ydb.CostBasedOptimization`

Value	Optimizer behavior
on	Cost-based optimizer is disabled for the current query
off	Cost-based optimizer is disabled for the current query
auto	Cost-based optimizer works in accordance with the current CostBasedOptimizationLevel level

`ydb.CostBasedOptimizationLevel`

Level	Description
0	Cost-based optimizer is disabled.
1	Cost-based optimizer is disabled, but estimates are computed and available.
2	Cost-based optimizer is enabled only for queries that include column-oriented tables.
3	Cost-based optimizer is enabled for all queries, but `LookupJoin` is preferred for row-oriented tables.
4	Cost-based optimizer is enabled for all queries.

Note

The default level is 2

`ydb.OptimizerHints`

The pragma for query hints is desicribed in a separate section.

REPLACE INTO

> **Warning**
>
> Currently, mixing column-oriented tables and row-oriented tables in a single transaction is supported only if the transaction performs read operations; no writes are allowed. Support for read-write transactions involving both table types is under development.
>
> If a write transaction includes both types of tables, it fails with the following error: `Write transactions that use both row-oriented and column-oriented tables are disabled at current time`.

Saves data to a table, overwriting the rows based on the primary key. If the given primary key is missing, a new row is added to the table. If the given `PRIMARY_KEY` exists, the row is overwritten. The values of columns not involved in the operation are replaced by their default values.

> **Note**
>
> Unlike `INSERT INTO` and `UPDATE`, the queries `UPSERT INTO` and `REPLACE INTO` don't need to pre-fetch the data, hence they run faster.

Examples

- Setting values for `REPLACE INTO` using `VALUES`.

```
REPLACE INTO my_table (Key1, Key2, Value2) VALUES
    (1u, "One", 101),
    (2u, "Two", 102);
COMMIT;
```

- Fetching values for `REPLACE INTO` using a `SELECT`.

```
REPLACE INTO my_table
SELECT Key AS Key1, "Empty" AS Key2, Value AS Value1
FROM my_table1;
COMMIT;
```

REVOKE

The `REVOKE` command allows revoking access rights to schema objects for users or groups of users.

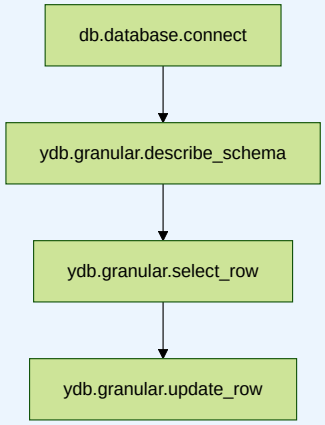
Syntax:

```
REVOKE [GRANT OPTION FOR] {{permission_name} [, ...] | ALL [PRIVILEGES]} ON {path_to_scheme_object [, ...]} F
ROM {role_name [, ...]}
```

- `permission_name` - the name of the access right to schema objects that needs to be revoked.
- `path_to_scheme_object` - the path to the schema object from which rights are revoked.
- `role_name` - the name of the user or group from which rights to the schema object are revoked.

`GRANT OPTION FOR` - using this clause revokes the right to manage access rights from the user or group. All rights previously granted by this user remain in effect. The clause functions similarly to revoking the `"ydb.access.grant"` right or `GRANT`.

Access rights



As names of access rights, you can use either the names of YDB rights or the corresponding YQL keywords.
The possible names of rights are listed in the table below.

YDB right	YQL keyword	Description
Database-level rights		
`ydb.database.connect`	`CONNECT`	The right to connect to a database
`ydb.database.create`	`CREATE`	The right to create new databases in the cluster
`ydb.database.drop`	`DROP`	The right to delete databases in the cluster
Elementary rights for database objects		
`ydb.granular.select_row`	`SELECT ROW`	The right to read rows from a table (select), read messages from topics, use secret values
`ydb.granular.update_row`	`UPDATE ROW`	The right to update rows in a table (insert, update, upsert, replace), write messages to topics
`ydb.granular.erase_row`	`ERASE ROW`	The right to delete rows from a table (delete)
`ydb.granular.create_directory`	`CREATE DIRECTORY`	The right to create and delete directories, including existing and nested ones
`ydb.granular.create_table`	`CREATE TABLE`	The right to create tables (including index, external, columnar), views, sequences
`ydb.granular.create_queue`	`CREATE QUEUE`	The right to create topics
`ydb.granular.remove_schema`	`REMOVE SCHEMA`	The right to delete objects (directories, tables, topics) that were created using rights
`ydb.granular.describe_schema`	`DESCRIBE SCHEMA`	The right to view existing access rights (ACL) on an access object, view descriptions of access objects (directories, tables, topics)
`ydb.granular.alter_schema`	`ALTER SCHEMA`	The right to modify access objects (directories, tables, topics), including users' rights to access objects
Additional flags		
`ydb.access.grant`	`GRANT`	The right to grant or revoke rights from other users to the extent not exceeding the current scope of the user's rights on the access object
`ydb.tables.modify`	`MODIFY TABLES`	`ydb.granular.update_row` + `ydb.granular.erase_row`
`ydb.tables.read`	`SELECT TABLES`	Alias for `ydb.granular.select_row`
`ydb.generic.list`	`LIST`	Alias for `ydb.granular.describe_schema`
`ydb.generic.read`	`SELECT`	`ydb.granular.select_row` + `ydb.generic.list`
`ydb.generic.write`	`INSERT`	`ydb.granular.update_row` + `ydb.granular.erase_row` + `ydb.granular.create_directory` + `ydb.granular.create_table` + `ydb.granular.create_queue` + `ydb.granular.remove_schema` + `ydb.granular.alter_schema`
`ydb.generic.use_legacy`	`USE LEGACY`	`ydb.generic.read` + `ydb.generic.write` + `ydb.access.grant`
`ydb.generic.use`	`USE`	`ydb.generic.use_legacy` + `ydb.database.connect`
`ydb.generic.manage`	`MANAGE`	`ydb.database.create` + `ydb.database.drop`
`ydb.generic.full_legacy`	`FULL LEGACY`	`ydb.generic.use_legacy` + `ydb.generic.manage`
`ydb.generic.full`	`FULL`	`ydb.generic.use` + `ydb.generic.manage`

- `ALL [PRIVILEGES]` is used to specify all possible rights on schema objects for users or groups. `PRIVILEGES` is an optional keyword needed for compatibility with the SQL standard.

Note

Rights `ydb.database.connect`, `ydb.granular.describe_schema`, `ydb.granular.select_row`, and `ydb.granular.update_row` should be considered as layers of rights.

For example, to update rows, you need not only the right `ydb.granular.update_row`, but also all the overlying rights.

Examples

- Revoke the `ydb.generic.read` right on the table `/shop_db/orders` from user `user1`:

  ```
  REVOKE 'ydb.generic.read' ON `/shop_db/orders` FROM user1;
  ```

  The same command, using the keyword:

  ```
  REVOKE SELECT ON `/shop_db/orders` FROM user1;
  ```

- Revoke the rights `ydb.database.connect`, `ydb.generic.list` on the root of the database `/shop_db` from user `user2` and group `group1`:

  ```
  REVOKE LIST, CONNECT ON `/shop_db` FROM user2, group1;
  ```

- Revoke the `ydb.generic.use` right on the tables `/shop_db/orders` and `/shop_db/sellers` from users `user1@domain` and `user2@domain`:

  ```
  REVOKE 'ydb.generic.use' ON `/shop_db/orders`, `/shop_db/sellers` FROM `user1@domain`, `user2@domain`;
  ```

- Revoke all rights on the table `/shop_db/sellers` from user `user`:

  ```
  REVOKE ALL ON `/shop_db/sellers` FROM user;
  ```

RESTORE

The `RESTORE` statement restores tables from a backup collection.

```
RESTORE collection_name;
```

Parameters

- `collection_name` — name of the backup collection to restore from.

Restore behavior

The restore operation:

- Finds the **current chain** of backups in the collection (the latest full backup followed by its incremental backups).
- Restores tables to the state of the **most recent** backup in that chain: applies the full backup and all subsequent incrementals in sequence.
- Fails if any of the tables being restored already exists at the same path.

Restoring to an arbitrary point "between" two saved backups is not supported: the result is always the state captured by one of the backups in the chain.

> **Warning**
>
> The restore operation fails if any of the tables being restored already exists at the same path. Rename or drop the conflicting tables before restoring.

Examples

Restoring from a backup collection:

```
-- Restore all tables from the collection
RESTORE production_backups;
```

Monitoring restore operations

Restore operations run asynchronously in the background. You can monitor their progress using YDB CLI:

```
# List backup and restore operations
ydb operation list incbackup

# Get operation details
ydb operation get <operation-id>
```

- Backup collections
- CREATE BACKUP COLLECTION
- BACKUP
- DROP BACKUP COLLECTION
- Backup and recovery guide

SELECT

Returns the result of evaluating the expressions specified after `SELECT`.

Can be used in combination with other operations to achieve a different effect.

Examples

```
SELECT "Hello, world!";
```

```
SELECT 2 + 2;
```

Procedure for executing SELECT

The result of the `SELECT` query is computed as follows:

- the set of input tables is determined: expressions after FROM are evaluated
- is computed SAMPLE / TABLESAMPLE
- FLATTEN COLUMNS or FLATTEN BY is performed; aliases specified in `FLATTEN BY` become visible after this point.
- All JOIN are executed.
- columns specified in GROUP BY ... AS ... are added (or replaced) to the resulting data
- the WHERE clause is executed: all data that does not satisfy the predicate is filtered out.
- GROUP BY is performed, aggregate function values are computed.
- Filtering is performed using HAVING
- Values of window functions are computed
- Expressions in `SELECT` are evaluated.
- expressions in `SELECT` are assigned names defined by aliases.
- a top-level DISTINCT is applied to the columns obtained in this way
- All subqueries in UNION ALL are computed in the same way and combined (see PRAGMA AnsiOrderByLimitInUnionAll).
- Sorting is performed according to ORDER BY
- OFFSET and LIMIT are applied to the result.

Column order in YQL

In standard SQL, the order of columns specified in the projection (in `SELECT`) matters. Besides the fact that the column order must be preserved when displaying query results or when writing to a new table, some SQL constructs use this order. This applies in particular to UNION ALL and positional ORDER BY (ORDER BY ordinal).

By default, the order of columns is ignored in YQL:

- the order of columns in output tables and in query results is undefined
- The data schema of the `UNION ALL` result is output by column names, not by positions.

When `PRAGMA OrderedColumns;` is enabled, the order of columns is preserved in the query results and is derived from the order of columns in the input tables according to the following rules:

- `SELECT` with explicit column enumeration sets the corresponding order.
- `SELECT` with an asterisk (`SELECT * FROM ...`) inherits the order from its input.
- the order of columns after JOIN: first the columns from the left side, then from the right. If the order of either side present in the output `JOIN` is not defined, the order of the result columns is also not defined;
- the order of depends on the execution mode of `UNION ALL`.
- Column order for AS_TABLE is not defined.

Combination of queries

Results of multiple SELECT (or subqueries) can be combined using the keywords `UNION` and `UNION ALL`.

```
query1 UNION [ALL] query2 (UNION [ALL] query3 ...)
```

Union of more than two queries is interpreted as a left-associative operation, i.e.

```
query1 UNION query2 UNION ALL query3
```

is interpreted as

```
(query1 UNION query2) UNION ALL query3
```

If `ORDER BY/LIMIT/DISCARD/INTO RESULT` is present in the combined subqueries, the following rules apply:

- `ORDER BY/LIMIT/INTO RESULT` is allowed only after the last subquery
- `DISCARD` is allowed only before the first subquery.
- the specified operators act on the result `UNION [ALL]`, not on the subquery
- to apply an operator to a subquery, the subquery must be enclosed in parentheses.

Accessing multiple tables in a single query

In standard SQL, UNION ALL is used to query multiple tables, which combines the results of two or more `SELECT`. This is not very convenient for a use case where you need to run the same query across multiple tables (for example, containing data for different dates). In YQL, for convenience, in `SELECT` after `FROM` you can specify not only a single table or subquery, but also call built-in functions that allow combining data from multiple tables.

The following functions are defined for these purposes:

`CONCAT(`table1`, `table2`, `table3` VIEW view_name, ...)` — combines all tables listed in the arguments.

`EACH($list_of_strings)` or `EACH($list_of_strings VIEW view_name)` — combines all tables whose names are listed in the string list. Optionally, you can pass multiple lists in separate arguments, similar to `CONCAT`.

`RANGE(`prefix`, `min`, `max`, `suffix`, `view`)`: combines a range of tables. Arguments:

- prefix — directory for searching tables, specified without a trailing slash. The only required argument; if only it is specified, all tables in this directory are used.
- min, max — the next two arguments specify a range of names for including tables. The range is inclusive on both ends. If the range is not specified, all tables in the prefix directory are used. Names of tables or directories located in the directory specified in prefix are compared with the range `[min, max]` lexicographically, not concatenated, so it is important to specify the range without leading slashes.
- suffix — table name. Expected without a leading slash. If suffix is not specified, the arguments `[min, max]` specify a range of table names. If suffix is specified, the arguments `[min, max]` specify a range of folders in which a table with the name specified in the suffix argument exists.

`LIKE(`prefix`, `pattern`, `suffix`, `view`)` и `REGEXP(`prefix`, `pattern`, `suffix`, `view`)` — the pattern argument is specified in a format similar to the binary operators of the same name: LIKE and REGEXP.

`FILTER(`prefix`, `callable`, `suffix`, `view`)` — the callable argument must be a callable expression with signature `(String)->Bool`, which will be called for each table/subdirectory in the prefix directory. Only those tables for which the callable value returned `true` will participate in the query. As a callable value, it is most convenient to use lambda functions.

> **Warning**
>
> The order in which tables are merged by all the above functions is not guaranteed.
>
> The list of tables is computed **before** the query itself is executed. Therefore, tables created during the query will not be included in the function results.

By default, schemas of all participating tables are merged according to the rules of UNION ALL. If schema merging is not desired, you can use functions with the suffix `_STRICT`, for example `CONCAT_STRICT` or `RANGE_STRICT`, which work exactly like the original ones but treat any discrepancy in table schemas as an error.

To specify the cluster of the merged tables, you need to specify it before the function name.

All arguments of the functions described above can be declared separately using named expressions. In this case, simple expressions are also allowed in them by implicitly calling EvaluateExpr.

The name of the source table from which each row was originally obtained can be obtained using the TablePath() function.

Examples

```
SELECT * FROM CONCAT(
  `table1`,
  `table2`,
  `table3`);
```

```
$indices = ListFromRange(1, 4);
$tables = ListMap($indices, ($index) -> {
    RETURN "table" || CAST($index AS String);
});
SELECT * FROM EACH($tables); -- identical to the previous example
```

```
SELECT * FROM RANGE(`my_folder`);
```

```
SELECT * FROM some_cluster.RANGE( -- The cluster can be specified before the function name
  `my_folder`,
  `from_table`,
  `to_table`);
```

```
SELECT * FROM RANGE(
  `my_folder`,
  `from_folder`,
  `to_folder`,
  `my_table`);
```

```
SELECT * FROM RANGE(
  `my_folder`,
  `from_table`,
  `to_table`,
  ``,
  `my_view`);
```

```
SELECT * FROM LIKE(
  `my_folder`,
  "2017-03-%"
);
```

```
SELECT * FROM REGEXP(
  `my_folder`,
  "2017-03-1[2-4]?"
);
```

```
$callable = ($table_name) -> {
    return $table_name > "2017-03-13";
};

SELECT * FROM FILTER(
  `my_folder`,
  $callable
);
```

Supported constructs in SELECT

- FROM
- FROM AS_TABLE
- FROM SELECT
- DISTINCT
- UNIQUE DISTINCT
- UNION
- WITH
- WITHOUT
- WHERE
- ORDER BY
- ASSUME ORDER BY
- LIMIT OFFSET
- SAMPLE
- TABLESAMPLE
- JOIN
- GROUP BY
- FLATTEN
- WINDOW
- VIEW secondary_index
- VIEW vector_index
- VIEW fulltext_index
- VIEW json_index

FROM

Data source for `SELECT`. The argument can accept the table name, the result of another `SELECT`, or a named expression. Between `SELECT` and `FROM`, list the comma-separated column names from the source (or `*` to select all columns).

Examples

```
SELECT key FROM my_table;
```

```
SELECT * FROM
  (SELECT value FROM my_table);
```

```
$table_name = "my_table";
SELECT * FROM $table_name;
```

FROM AS_TABLE

Accessing named expressions as tables using the `AS_TABLE` function.

`AS_TABLE($variable)` lets you use the value of `$variable` as the data source for the query. In this case, the variable `$variable` must have the type `List<Struct<...>>`.

Example

```
$data = AsList(
    AsStruct(1u AS Key, "v1" AS Value),
    AsStruct(2u AS Key, "v2" AS Value),
    AsStruct(3u AS Key, "v3" AS Value));

SELECT Key, Value FROM AS_TABLE($data);
```

You should either explicitly specify the modifiable columns in both the source and the target when using expressions with modifying queries such as UPSERT INTO or INSERT INTO:

```
$data = AsList(
    AsStruct(1u AS Key, "v1" AS Value),
    AsStruct(2u AS Key, "v2" AS Value),
    AsStruct(3u AS Key, "v3" AS Value));

INSERT INTO `my_table` (Key, Value) SELECT Key, Value FROM AS_TABLE($data);
```

Or you should omit them completely:

```
$data = AsList(
    AsStruct(1u AS Key, "v1" AS Value),
    AsStruct(2u AS Key, "v2" AS Value),
    AsStruct(3u AS Key, "v3" AS Value));

INSERT INTO `my_table` SELECT * FROM AS_TABLE($data);
```

FROM ... SELECT ...

An inverted format, first specifying the data source and then the operation.

Examples

```
FROM my_table SELECT key, value;
```

```
FROM a_table AS a
JOIN b_table AS b
USING (key)
SELECT *;
```

FLATTEN

FLATTEN BY

Converts rows in the source table using vertical unpacking of containers of variable length (lists or dictionaries).

For example:

- Source table:

[a, b, c]	1
[d]	2
[]	3

- The table resulting from `FLATTEN BY` on the left column:

a	1
b	1
c	1
d	2

YDB tables don't support container types, so the FLATTEN BY function can only be applied to table-type variables created within a YQL query.

Example

```
$sample = AsList(
    AsStruct(AsList('a','b','c') AS value, CAST(1 AS Uint32) AS id),
    AsStruct(AsList('d') AS value, CAST(2 AS Uint32) AS id),
    AsStruct(AsList() AS value, CAST(3 AS Uint32) AS id)
);

SELECT value, id FROM as_table($sample) FLATTEN BY (value);
```

This conversion can be convenient in the following cases:

- When it is necessary to output statistics by cells from a container column (for example, via `GROUP BY`).
- When the cells in a container column store IDs from another table that you want to join with `JOIN`.

Syntax

- `FLATTEN BY` is specified after `FROM`, but before `GROUP BY`, if `GROUP BY` is present in the query.
- The type of the result column depends on the type of the source column:

Container type	Result type	Comments
`List<X>`	`X`	List cell type
`Dict<X,Y>`	`Tuple<X,Y>`	Tuple of two elements containing key-value pairs
`Optional<X>`	`X`	The result is almost equivalent to the clause `WHERE foo IS NOT NULL`, but the `foo` column type is changed to `X`

- By default, the result column replaces the source column. Use `FLATTEN BY foo AS bar` to keep the source container. As a result, the source container is still available as `foo` and the output container is available as `bar`.
- To build a Cartesian product of multiple container columns, use the clause `FLATTEN BY (a, b, c)`. Parentheses are mandatory to avoid grammar conflicts.
- Inside `FLATTEN BY`, you can only use column names from the input table. To apply `FLATTEN BY` to the calculation result, use a subquery.
- In `FLATTEN BY` you can use both columns and arbitrary named expressions (unlike columns, `AS` is required in this case). To avoid grammatical ambiguities of the expression after `FLATTEN BY`, make sure to use parentheses with the following: `... FLATTEN BY (ListSkip(col, 1) AS col) ...`
- If the source column had nested containers, for example, `List<DictX,Y>`, `FLATTEN BY` unpacks only the outer level. To completely unpack the nested containers, use a subquery.

> **Note**
>
> `FLATTEN BY` interprets optional data types as lists of length 0 or 1. The table rows with `NULL` are skipped, and the column type changes to a similar non-optional type.
>
> `FLATTEN BY` makes only one conversion at a time, so use `FLATTEN LIST BY` or `FLATTEN OPTIONAL BY` on optional containers, for example, `Optional<List<String>>`.

Specifying the container type

To specify the type of container to convert to, you can use:

- `FLATTEN LIST BY`

  For `Optional<List<T>>`, `FLATTEN LIST BY` will unpack the list, treating `NULL` as an empty list.
- `FLATTEN DICT BY`

For `Optional<Dict<T>>`, `FLATTEN DICT BY` will unpack the dictionary, interpreting `NULL` as an empty dictionary.

- `FLATTEN OPTIONAL BY`

  To filter the `NULL` values without serialization, specify the operation by using `FLATTEN OPTIONAL BY`.

Examples

```
SELECT
  t.item.0 AS key,
  t.item.1 AS value,
  t.dict_column AS original_dict,
  t.other_column AS other
FROM my_table AS t
FLATTEN DICT BY dict_column AS item;
```

```
SELECT * FROM (
    SELECT
        AsList(1, 2, 3) AS a,
        AsList("x", "y", "z") AS b
) FLATTEN LIST BY (a, b);
```

```
SELECT * FROM (
    SELECT
        "1;2;3" AS a,
        AsList("x", "y", "z") AS b
) FLATTEN LIST BY (String::SplitToList(a, ";") as a, b);
```

Analogues of FLATTEN BY in other DBMS

- PostgreSQL: `unnest`
- Hive: `LATERAL VIEW`
- MongoDB: `unwind`
- Google BigQuery: `FLATTEN`
- ClickHouse: `ARRAY JOIN / arrayJoin`

FLATTEN COLUMNS

Converts a table where all columns must be structures to a table with columns corresponding to each element of each structure from the source columns.

The names of the source column structures are not used and not returned in the result. Be sure that the structure element names aren't repeated in the source columns.

Example

```
SELECT x, y, z
FROM (
  SELECT
    AsStruct(
        1 AS x,
        "foo" AS y),
    AsStruct(
        false AS z)
) FLATTEN COLUMNS;
```

GROUP BY

Groups the results of `SELECT` by the values of specified columns or expressions. Together with `GROUP BY`, aggregate functions (`COUNT`, `MAX`, `MIN`, `SUM`, `AVG`) are often used to perform calculations in each group.

If `GROUP BY` is present in the query, then when selecting columns (between `SELECT ... FROM`), the following constructs are allowed:

1. Columns by which grouping is performed (present in the `GROUP BY` argument).
2. Aggregate functions (see the next section). Columns that are **not** grouped by can only be included as arguments of an aggregate function.
3. Functions that return the start and end time of the current window (`HOP_START` and `HOP_END`) (for `GROUP BY HOP`).
4. Arbitrary computations combining items 1-3.

It is possible to group by the result of evaluating an arbitrary expression on the source columns. In this case, to access the result of this expression, it is recommended to assign it a name using `AS`, see the second example.

Syntax

```
SELECT                            -- In SELECT you can use:
    column1,                      -- key columns specified in GROUP BY
    key_n,                        -- named expressions specified in GROUP BY
    column1 + key_n,              -- arbitrary non-aggregate functions on them
    Aggr_Func1( column2 ),        -- aggregate functions containing any columns in their arguments,
    Aggr_Func2( key_n + column2 ), --   including named expressions specified in GROUP BY
    ...
FROM table
GROUP BY
    column1, column2, ...,
    <expr> AS key_n           -- When grouping by an expression, it can be given a name via AS,
                              -- which can be used in SELECT
```

A query of the form `SELECT * FROM table GROUP BY k1, k2, ...` returns all columns listed in GROUP BY, that is, it is equivalent to the query `SELECT DISTINCT k1, k2, ... FROM table`.

The asterisk can also be used as an argument of the aggregate function `COUNT`. `COUNT(*)` means "number of rows in the group".

Note

Aggregate functions do not consider `NULL` in their arguments, except for the function `COUNT`.

Also in YQL, there is a mechanism of aggregate function factories, implemented using the functions `AGGREGATION_FACTORY` and `AGGREGATE_BY`.

Examples

```
SELECT key, COUNT(*) FROM my_table
GROUP BY key;
```

```
SELECT double_key, COUNT(*) FROM my_table
GROUP BY key + key AS double_key;
```

```
SELECT
   double_key,                          -- OK: key column
   COUNT(*) AS group_size,              -- OK: COUNT(*)
   SUM(key + subkey) AS sum1,           -- OK: aggregate function
   CAST(SUM(1 + 2) AS String) AS sum2,  -- OK: aggregate function with constant argument
   SUM(SUM(1) + key) AS sum3,           -- ERROR: nested aggregations are not allowed
   key AS k1,                           -- ERROR: using non-key column key without aggregation
   key * 2 AS dk1,                      -- ERROR in YQL: using non-key column key without aggregation
FROM my_table
GROUP BY
  key * 2 AS double_key,
  subkey as sk,
```

Warning

The ability to specify a name for a column or expression in `GROUP BY .. AS foo` is a YQL extension. Such a name becomes visible in `WHERE` despite the fact that filtering by `WHERE` is performed earlier than grouping. In particular, if the `T` table has two columns `foo` and `bar`, then in the `SELECT foo FROM T WHERE foo > 0 GROUP BY bar AS foo` query filtering will actually occur on the `bar` column from the original table.

GROUP BY ... SessionWindow()

YQL supports grouping by sessions. You can add a special function `SessionWindow` to the regular expressions in `GROUP BY`:

```
SELECT
  user,
  session_start,
  SessionStart() AS same_session_start, -- same as session_start
  COUNT(*) AS session_size,
  SUM(value) AS sum_over_session,
FROM my_table
GROUP BY user, SessionWindow(<time_expr>, <timeout_expr>) AS session_start
```

The following happens:

1. The input table is partitioned by the grouping keys specified in `GROUP BY`, ignoring SessionWindow (in this case, by `user`). If there is nothing else in `GROUP BY` besides SessionWindow, the input table falls into a single partition
2. Each partition is divided into non-overlapping subsets of rows (sessions). To do this, the partition is sorted in ascending order of the value of expression `time_expr`. Session boundaries are drawn between adjacent elements of the partition whose difference in `time_expr` values exceeds `timeout_expr`
3. The sessions obtained in this way are the final partitions on which aggregate functions are computed.

The key column of SessionWindow() (in the example, `session_start`) has the value "minimum `time_expr` in the session". Additionally, when SessionWindow() is present in `GROUP BY`, the special aggregate function SessionStart can be used.

An extended version of SessionWindow with four arguments is also supported:

`SessionWindow(<order_expr>, <init_lambda>, <update_lambda>, <calculate_lambda>)`

Here:

- `<order_expr>` – expression by which the original partition is sorted
- `<init_lambda>` – lambda function for initializing the session calculation state. It has the signature `(TableRow())->State`. It is called once on the first element (in sort order) of the original partition
- `<update_lambda>` – lambda function for updating the session calculation state and determining session boundaries. It has the signature `(TableRow(), State)->Tuple<Bool, State>`. It is called on each element of the original partition except the first. The new state value is computed based on the current table row and the previous state. If the first element of the returned tuple has the value `True`, then a new session starts from the *current* row. The key of the new session is obtained by applying `<calculate_lambda>` to the second element of the tuple.
- `<calculate_lambda>` – a lambda function for computing the session key (the "value" of SessionWindow(), which is also available via SessionStart()). The function has the signature `(TableRow(), State)->SessionKey`. It is called on the first element of a partition (after `<init_lambda>`) and on those elements for which `<update_lambda>` returned `True` as the first element of the tuple. It is worth noting that to start a new session, `<calculate_lambda>` must return a value that differs from the previous session key. At the same time, sessions with the same keys are not merged. For example, if `<calculate_lambda>` sequentially returns `0, 1, 0, 1`, then these will be four different sessions.

Using the extended version of SessionWindow, you can solve, for example, the following problem: split a partition into sessions as in the two-argument version of SessionWindow, but with a limit on the maximum session length set to some constant:

Example

```
$max_len = 1000; -- maximum session length
$timeout = 100; -- timeout (timeout_expr in the simplified version of SessionWindow)

$init = ($row) -> (AsTuple($row.ts, $row.ts)); -- session state - a tuple of 1) the value of the time column
ts on the first row of the session and 2) on the current row
$update = ($row, $state) -> {
  $is_end_session = $row.ts - $state.0 > $max_len OR $row.ts - $state.1 > $timeout;
  $new_state = AsTuple(IF($is_end_session, $row.ts, $state.0), $row.ts);
  return AsTuple($is_end_session, $new_state);
};
$calculate = ($row, $state) -> ($row.ts);
SELECT
  user,
  session_start,
  SessionStart() AS same_session_start, -- same as session_start
  COUNT(*) AS session_size,
  SUM(value) AS sum_over_session,
FROM my_table
GROUP BY user, SessionWindow(ts, $init, $update, $calculate) AS session_start
```

`SessionWindow` can be used in `GROUP BY` only once.

ROLLUP, CUBE, and GROUPING SETS

Results of aggregate function computation as subtotals for groups and grand totals for individual columns or the entire table.

Syntax

```
SELECT
    c1, c2,                          -- columns by which grouping is performed

AGGREGATE_FUNCTION(c3) AS outcome_c  -- aggregate function (SUM, AVG, MIN, MAX, COUNT)

FROM table_name

GROUP BY
    GROUP_BY_EXTENSION(c1, c2)       -- GROUP BY extension: ROLLUP, CUBE, or GROUPING SETS
```

- `ROLLUP`: groups column values in the order they are listed in the arguments (strictly from left to right), forming subtotals for each group and a grand total.

- `CUBE` — groups values for all possible combinations of columns, forming subtotals for each group and a grand total.
- `GROUPING SETS` — specifies groups for subtotals.

`ROLLUP`, `CUBE`, and `GROUPING SETS` can be combined with a comma.

GROUPING

In the subtotal, the values of columns not involved in calculations are replaced with `NULL`. In the grand total, the values of all columns are replaced with `NULL`. `GROUPING` is a function that allows you to distinguish the original `NULL` values from the `NULL` values that were added when generating the grand and intermediate totals.

`GROUPING` returns a bitmask:

- `0` — `NULL` for the original empty value.
- `1` — `NULL`, added for intermediate or grand total.

Example

```
SELECT
    column1,
    column2,
    column3,

    CASE GROUPING(
        column1,
        column2,
        column3,
    )
        WHEN 1  THEN "Subtotal: column1 and column2"
        WHEN 3  THEN "Subtotal: column1"
        WHEN 4  THEN "Subtotal: column2 and column3"
        WHEN 6  THEN "Subtotal: column3"
        WHEN 7  THEN "Grand total"
        ELSE         "Individual group"
    END AS subtotal,

    COUNT(*) AS rows_count

FROM my_table

GROUP BY
    ROLLUP(
        column1,
        column2,
        column3
    ),
    GROUPING SETS(
        (column2, column3),
        (column3)
        -- if you add (column2) here as well, then in total
        -- these ROLLUP and GROUPING SETS would give a result,
        -- similar to CUBE
    )
;
```

DISTINCT

Applying aggregate functions only to unique column values.

> **Note**
>
> Applying `DISTINCT` to computed values is not currently implemented. For this purpose, you can use a subquery or the `GROUP BY ... AS ...` expression.

Example

```
SELECT
  key,
  COUNT(DISTINCT value) AS count -- top 3 keys by number of unique values
FROM my_table
GROUP BY key
ORDER BY count DESC
LIMIT 3;
```

Also, the `DISTINCT` keyword can be used to select unique rows through `SELECT DISTINCT`.

COMPACT

Having the SQL hint `COMPACT` immediately after the keyword `GROUP` allows more efficient aggregation in cases where the query author knows in advance that none of the aggregation keys will have a large amount of data (on the order of a gigabyte or a million rows). If this assumption is not met, the operation may fail with an Out of Memory error or start working significantly slower compared to a regular GROUP BY.

Unlike a regular GROUP BY, the Map-side combiner stage and additional Reduce for each field with DISTINCT aggregation are disabled.

Example

```
SELECT
  key,
  COUNT(DISTINCT value) AS count -- top 3 keys by number of unique values
FROM my_table
GROUP /*+ COMPACT() */ BY key
ORDER BY count DESC
LIMIT 3;
```

GROUP BY ... HOP

`HOP` groups data by overlapping time windows (hopping windows). It is supported both in analytical queries to tables and in streaming queries to topics.

```
HOP(time_extractor, hop, interval, delay)
```

Where:

- `time_extractor` — SQL expression of type `Timestamp` that defines the event time. A timestamp is calculated from each input row, which determines the window assignment.
- `hop` : step between the starts of adjacent windows in ISO 8601 format, for example `"PT10S"` (10 seconds).
- `interval` — the size (duration) of each window in ISO 8601 format, for example `"PT30S"` (30 seconds).
- — `delay` for closing a window after its completion in ISO 8601 format. Used only in streaming queries (ignored when working with tables). For streaming queries, it is recommended to use HoppingWindow with watermarks instead of `delay`.

Also available are aggregate functions `HOP_START()` and `HOP_END()` , which return the start and end timestamps of the current window of type `Timestamp` respectively.

Description

Let's break down the algorithm using an example.

```
GROUP BY HOP(CAST(ts AS Timestamp), "PT10S", "PT30S", "PT20S")
```

In this example, `CAST(ts AS Timestamp)` extracts the event time from the `ts` column. The `hop` parameter is 10 seconds, `interval` is 30 seconds, `delay` is 20 seconds.

Windows are constructed according to the following rule:

- Window starts are aligned to moments that are multiples of `hop` (10 seconds), starting from 0: 0, 10, 20, and so on.
- The duration of each window is `interval` (30 seconds). The resulting windows are: `[0; 30)` , `[10; 40)` , `[20; 50)` , and so on.
- An event falls into all windows whose time range includes its time. For example, an event with a time of 25 seconds falls into windows `[0; 30)` , `[10; 40)` , and `[20; 50)` .
- A window is considered completed when an event with a timestamp not less than the end of this window + `delay` (20 seconds) is received. For example, window `[10; 40)` closes when an event with a timestamp of 60 or more is received.

Analytical `HOP` over a table

When working with tables, data is grouped by `GROUP BY` keys (ignoring `HOP`), forming groups of rows (hereinafter groups). Inside each group:

1. Rows are sorted in ascending order of `time_extractor` .
2. Each row is assigned to one or more overlapping windows.
3. On each window, the specified aggregate functions are computed.

The `delay` parameter is **not used** in analytical table processing: the data is already fully available, the traversal order is set by sorting by `time_extractor` , and the window completion is determined by the full group scan algorithm (see the closing rule in the description above).

Streaming `HOP` over a topic

When working with topics, data is grouped by `GROUP BY` keys (ignoring `HOP`), forming groups. Inside each group:

1. Events are processed in an order close to ascending `time_extractor` . Small deviations from strict order are allowed.
2. Each event is assigned to one or more overlapping windows.
3. On each window, the specified aggregate functions are computed.

In streaming queries, events may arrive not in strict chronological order. The `delay` parameter sets the waiting time after the formal window completion: the window does not close immediately, but after `delay` seconds, to give delayed events time to arrive. Events that arrive after the window is closed are ignored.

Limitations

`time_extractor` is an SQL expression that depends only on the input column values and must have type `Timestamp` .

To specify `hop` , `interval` , and `delay` , a string expression conforming to the ISO 8601 standard is used, for example, `PT10S` — 10 seconds, `PT1M` — 1 minute. This is the format used to construct the built-in type `Interval` from a string.

The values of parameters `interval` and `delay` must be divisible by the value of parameter `hop` . This requirement ensures alignment of window boundaries: each window starts at a time that is a multiple of `hop` and ends exactly after `interval` , which guarantees uniform coverage of the time axis without gaps. Parameters `hop` and `interval` must be positive.

Examples

```
SELECT
    sensor_id,
    HOP_END() AS window_end,
    AVG(temperature) AS avg_temp,
    COUNT(*) AS event_count
FROM sensor_data
GROUP BY
    sensor_id,
    HOP(CAST(event_time AS Timestamp), "PT10S", "PT1M", "PT30S");
```

GROUP BY ... HoppingWindow

groups events by overlapping time windows (hopping windows), similar to GROUP BY `HoppingWindow`. It is supported both in analytical queries to tables and in stream queries to topics. The main difference from `HOP` is that in stream queries, `HoppingWindow` uses the watermarks mechanism to determine when to close a window instead of a fixed parameter `delay`.

```
HoppingWindow(time_extractor, hop, interval)
```

Where:

- `time_extractor` : an SQL expression of type `Timestamp` that defines the event time. It must depend only on input columns.
- `hop` : the step (shift period) between the starts of adjacent windows in ISO 8601 format, for example `"PT10S"` (10 seconds).
- `interval` : the size (duration) of each window in ISO 8601 format, for example `"PT1M"` (1 minute). The value `interval` must be divisible by `hop`, because windows are aligned to multiples of the step interval.

The functions `HOP_START()` and `HOP_END()` are also available, returning timestamps of the start and end of the current window.

The window construction algorithm is the same as GROUP BY HOP: windows start at moments that are multiples of `hop` and have a duration of `interval`. An event falls into all windows whose time range includes its time.

Analytical `HoppingWindow` over a table

When working with tables, `HoppingWindow` performs grouping by time windows similarly to HOP, but without the `delay` parameter, which was always ignored in analytical use (the data in the table is already sorted).

1. The input table is partitioned by the grouping keys specified in `GROUP BY`, ignoring `HoppingWindow`.
2. Each partition is sorted by ascending `time_extractor`.
3. Each partition is divided into overlapping subsets of events (windows).
4. The specified aggregate functions are computed on each subset.

Streaming `HoppingWindow` over a topic

When working with topics, `HoppingWindow` uses watermarks to determine when to close a window. A window is closed when the watermark value is not less than the end of the window. This provides more accurate aggregation results compared to `HOP`, where the window is closed at a fixed `delay`.

1. The input topic is partitioned by the grouping keys specified in `GROUP BY`, ignoring `HoppingWindow`.
2. In each partition, the window advances independently of others.
3. Events are processed in an order close to ascending `time_extractor`. Minor reorderings of the input stream order are allowed.
4. Each partition is divided into overlapping subsets of events (windows).
5. A window is closed when a watermark is received whose value is not less than the end of the window. After closing, the aggregation result is output.
6. Events that arrive after the window is closed are not included in the results.

For `HoppingWindow` to work correctly in streaming mode, you need to configure the watermark in the WITH section of the source. For more information: Configuration.

Example

Below is streaming reading from a topic: in `SELECT` it is convenient to output the end of the window via `HOP_END()`. For **tables** in an analytical query, `HOP_START()` or `HOP_END()` are more often used, depending on which window boundary needs to be shown in the result; the meaning of the windows is the same, only the selected label differs.

```
SELECT
    key,
    HOP_END() AS window_end,
    COUNT(*) AS event_count
FROM
    my_topic
WITH (
    FORMAT = json_each_row,
    SCHEMA = (
        key String,
        event_time String
    ),
    WATERMARK = __ydb_write_time - Interval("PT5S")
)
GROUP BY
    key,
    HoppingWindow(__ydb_write_time, "PT10S", "PT1M");
```

HAVING

Filtering the `SELECT` result set based on the results of computing aggregate functions. The syntax is similar to the `WHERE` construct.

Example

```
SELECT
    key
FROM my_table
GROUP BY key
HAVING COUNT(value) > 100;
```

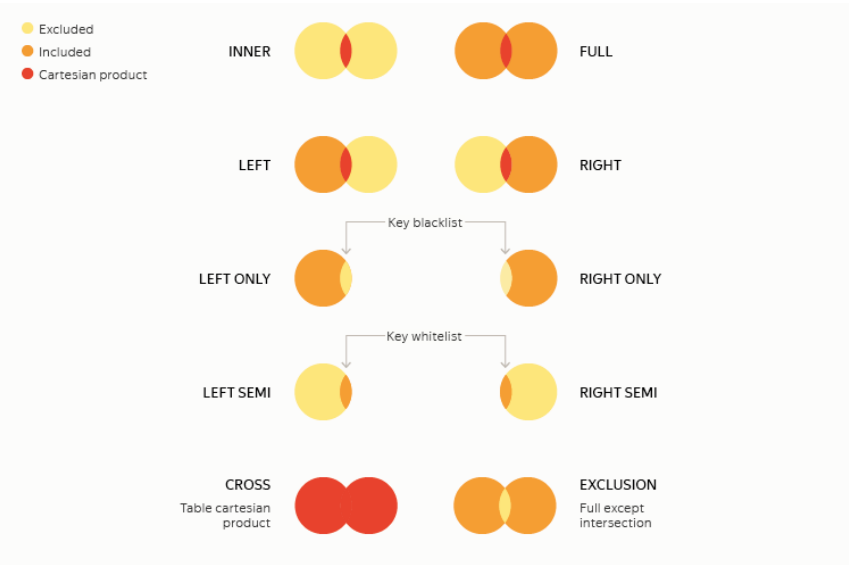
JOIN

It lets you combine multiple data sources (subqueries or tables) by equality of values in the specified columns or expressions (the `JOIN` keys).

Syntax

```
SELECT ...    FROM table_1
-- first JOIN step:
  <Join_Type> JOIN table_2 <Join_Condition>
  -- left subquery -- entries in table_1
  -- right subquery -- entries in table_2
-- next JOIN step:
  <Join_Type> JOIN table_n <Join_Condition>
  -- left subquery -- JOIN result in the previous step
  -- right subquery -- entries in table_n
-- JOIN can include the following steps
...
WHERE  ...
```

At each JOIN step, rules are used to establish correspondences between rows in the left and right data subqueries, creating a new subquery that includes every combination of rows that meet the JOIN conditions.



Attention!

Since columns in YQL are identified by their names, and you can't have two columns with the same name in the subquery, `SELECT * FROM ... JOIN ...` can't be executed if there are columns with identical names in the joined tables.

Types of join

- `INNER` (default): Rows from joined subqueries that don't match any rows on the other side won't be included in the result.
- `LEFT`: If there's no value in the right subquery, it adds a row to the result with column values from the left subquery, using `NULL` in columns from the right subquery
- `RIGHT`: If there's no value in the left subquery, it adds the row to the result, including column values from the right subquery, but using `NULL` in columns from the left subquery
- `FULL` = `LEFT` + `RIGHT`
- `LEFT/RIGHT SEMI`: One side of the subquery is a whitelist of keys, its values are not available. The result includes columns from one table only, no Cartesian product is created.
- `LEFT/RIGHT ONLY`: Subtracting the sets by keys (blacklist). It's almost the same as adding `IS NULL` to the key on the opposite side in the regular `LEFT/RIGHT` JOIN, but with no access to values: the same as `SEMI` JOIN.
- `CROSS`: A full Cartesian product of two tables without specifying key columns and no explicit `ON/USING`.
- `EXCLUSION`: Both sides minus the intersection.

Use `LEFT SEMI JOIN` instead of a correlated `EXISTS` subquery and `LEFT ONLY JOIN` instead of a correlated `NOT EXISTS` subquery. See Correlated subqueries, EXISTS, and NOT EXISTS.

Note

`NULL` is a special value to denote nothing. Hence, `NULL` values on both sides are not treated as equal to each other. This eliminates ambiguity in some types of `JOIN` and avoids a giant Cartesian product otherwise created.

Conditions for joining

For `CROSS JOIN`, no join condition is specified. The result includes the Cartesian product of the left and right subquery, meaning it combines everything with everything. The number of rows in the resulting subquery is the product of the number of rows in the left and right subqueries.

For any other JOIN types, specify the condition using one of the two methods:

1. `USING (column_name)`. Used if both the left and right subqueries share a column whose equality of values is a join condition.
2. `ON (equality_conditions)`. Lets you set a condition of equality for column values or expressions over columns in the left and right subqueries or use several such conditions combined by `and`.

Examples

```
SELECT    a.value as a_value, b.value as b_value
FROM      a_table AS a
FULL JOIN b_table AS b USING (key);
```

```
SELECT    a.value as a_value, b.value as b_value
FROM      a_table AS a
FULL JOIN b_table AS b ON a.key = b.key;
```

```
SELECT     a.value as a_value, b.value as b_value, c.column2
FROM       a_table AS a
CROSS JOIN b_table AS b
LEFT  JOIN c_table AS c ON c.ref = a.key and c.column1 = b.value;
```

To make sure no full scan of the right joined table is required, a secondary index can be applied to the columns included in the Join condition. Accessing a secondary index should be specified explicitly in `JOIN table_name VIEW index_name AS table_alias` format.

For example, creating an index to use in the Join condition:

```
ALTER TABLE b_table ADD INDEX b_index_ref GLOBAL ON(ref);
```

Using the created index:

```
SELECT    a.value as a_value, b.value as b_value
FROM      a_table AS a
INNER JOIN b_table VIEW b_index_ref AS b ON a.ref = b.ref;
```

OVER, PARTITION BY, and WINDOW

Window functions were introduced in the SQL:2003 standard and expanded in the SQL:2011 standard. They let you run calculations on a set of table rows that are related to the current row in some way.

Unlike aggregate functions, window functions don't group rows into one output row: the number of rows in the resulting table is always the same as in the source table.

If a query contains both aggregate and window functions, grouping is performed and aggregate function values are calculated first. The calculated values of aggregate functions can be used as window function arguments (but not the other way around).

Syntax

General syntax for calling a window function is as follows

```
function_name([expression [, expression ...]]) OVER (window_definition)
```

or

```
function_name([expression [, expression ...]]) OVER window_name
```

Here, window name (`window_name`) is an arbitrary ID that is unique within the query and `expression` is an arbitrary expression that contains no window function calls.

In the query, each window name must be mapped to the window definition (`window_definition`):

```
SELECT
    F0(...) OVER (window_definition_0),
    F1(...) OVER w1,
    F2(...) OVER w2,
    ...
FROM my_table
WINDOW
    w1 AS (window_definition_1),
    ...
    w2 AS (window_definition_2)
;
```

Here, the `window_definition` is written as

```
[ PARTITION BY (expression AS column_identifier | column_identifier) [, ...] ]
[ ORDER BY expression [ASC | DESC] ]
[ frame_definition ]
```

You can set an optional *frame definition* (`frame_definition`) one of two ways:

- `ROWS frame_begin`
- `ROWS BETWEEN frame_begin AND frame_end`

The frame start (`frame_begin`) and *frame end* (`frame_end`) are set one of the following ways:

- `UNBOUNDED PRECEDING`
- `offset PRECEDING`
- `CURRENT ROW`
- `offset FOLLOWING`
- `UNBOUNDED FOLLOWING`

Here, the *frame* `offset` is a non-negative numeric literal. If the frame end isn't set, the `CURRENT ROW` is assumed.

There should be no window function calls in any of the expressions inside the window definition.

Calculation algorithm

Partitioning

If `PARTITION BY` is set, the source table rows are grouped into *partitions*, which are then handled independently of each other.
If `PARTITION BY` isn't set, all rows in the source table are put in the same partition. If `ORDER BY` is set, it determines the order of rows in a partition.
Both in `PARTITION BY` and GROUP BY you can use aliases and SessionWindow.

If `ORDER BY` is omitted, the order of rows in the partition is undefined.

Frame

The `frame_definition` specifies a set of partition rows that fall into the *window frame* associated with the current row.

In `ROWS` mode (the only one that YQL currently supports), the window frame contains rows with the specified offsets relative to the current row in the partition. For example, if `ROWS BETWEEN 3 PRECEDING AND 5 FOLLOWING` is used, the window frame contains 3 rows preceding the current one, the current row, and 5 rows following it.

The set of rows in the window frame may change depending on which row is the current one. For example, for the first row in the partition, the `ROWS BETWEEN 3 PRECEDING AND 1 PRECEDING` window frame will have no rows.

Setting `UNBOUNDED PRECEDING` as the frame start means "from the first partition row" and `UNBOUNDED FOLLOWING` as the frame end — "up to the last partition row". Setting `CURRENT ROW` means "from/to the current row".

If no `frame_definition` is specified, a set of rows to be included in the window frame depends on whether there is `ORDER BY` in the `window_definition`.
Namely, if there is `ORDER BY`, then `ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW` is implicitly assumed. If none, then `ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING`.

Further, depending on the specific window function, it's calculated either based on the set of rows in the partition or the set of rows in the window frame.

List of available window functions

Examples

```
SELECT
    COUNT(*) OVER w AS rows_count_in_window,
    some_other_value -- access the current row
FROM `my_table`
WINDOW w AS (
    PARTITION BY partition_key_column
    ORDER BY int_column
);
```

```
SELECT
    LAG(my_column, 2) OVER w AS row_before_previous_one
FROM `my_table`
WINDOW w AS (
    PARTITION BY partition_key_column
);
```

```
SELECT
    -- AVG (like all aggregate functions used as window functions)
    -- is calculated on the window frame
    AVG(some_value) OVER w AS avg_of_prev_current_next,
    some_other_value -- access the current row
FROM my_table
WINDOW w AS (
    PARTITION BY partition_key_column
    ORDER BY int_column
    ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING
);
```

```
SELECT
    -- LAG doesn't depend on the window frame position
    LAG(my_column, 2) OVER w AS row_before_previous_one
FROM my_table
WINDOW w AS (
    PARTITION BY partition_key_column
    ORDER BY my_column
);
```

Implementation specifics

- Functions calculated on the `ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING` or `ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW` window frame are implemented efficiently (do not require additional memory and their computation runs on a partition in O(partition size) time).
- For the `ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING` window frame, you can choose the execution strategy in RAM by specifying the `COMPACT` hint after the `PARTITION` keyword.

  For example, `PARTITION COMPACT BY key` or `PARTITION COMPACT BY ()` (if `PARTITION BY` was missing initially).

  If the `COMPACT` hint is specified, this requires additional memory equal to O(partition size), but then no extra `JOIN` operation is made.
- If the window frame doesn't start with `UNBOUNDED PRECEDING`, calculating window functions on this window requires additional memory equal to O(the maximum number of rows from the window boundaries to the current row), while the computation time is equal to O(number_of_partition_rows * window_size).
- For the window frame starting with `UNBOUNDED PRECEDING` and ending with `N`, where `N` is neither `CURRENT ROW` nor `UNBOUNDED FOLLOWING`, additional memory equal to O(N) is required and the computation time is equal to O(N * number_of_partition_rows).
- The `LEAD(expr, N)` and `LAG(expr, N)` functions always require O(N) of RAM.

Given the above, a query with `ROWS BETWEEN CURRENT ROW AND UNBOUNDED FOLLOWING` should, if possible, be changed to `ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW` by reversing the `ORDER BY` sorting order.

DISTINCT

Selecting unique rows.

> **Note**
>
> Applying `DISTINCT` to calculated values is not currently implemented. For this purpose, use a subquery or the clause `GROUP BY ... AS ...`.

Example

```
SELECT DISTINCT value -- only unique values from the table
FROM my_table;
```

The `DISTINCT` keyword can also be used to apply aggregate functions only to distinct values. For more information, see the documentation for GROUP BY.

Removes duplicate rows from the result. Applies after the clause `GROUP BY ... AS ...`.

UNIQUE DISTINCT hints

Directly after `SELECT`, it is possible to add SQL hints `unique` or `distinct`, which declare that this projection generates data containing unique values in the specified set of columns of a row-based or columnar table. This can be used to optimize subsequent subqueries executed on this projection, or for writing to table meta-attributes during `INSERT` (currently not supported for columnar tables).

- Columns are specified in the hint values, separated by spaces.
- If the set of columns is not specified, uniqueness applies to the entire set of columns in this projection.
- `unique` - indicates unique or `null` values. According to the SQL standard, each null is unique: `NULL = NULL` -> `NULL`.
- `distinct` - indicates completely unique values including null: `NULL IS DISTINCT FROM NULL` -> `FALSE`.
- Multiple sets of columns can be specified in several hints for a single projection.
- If the hint contains a column that is not in the projection, it will be ignored.

Combining subquery results (UNION)

UNION

Union of the results of the underlying queries, with duplicates removed.
Behavior is identical to using `UNION ALL` followed by `SELECT DISTINCT *`.
Refer to UNION ALL for more details.

Examples

```
SELECT key FROM T1
UNION
SELECT key FROM T2 -- returns the set of distinct keys in the tables
```

UNION ALL

Concatenating results of multiple `SELECT` statements (or subqueries).

Two `UNION ALL` modes are supported: by column names (the default mode) and by column positions (corresponds to the ANSI SQL standard and is enabled by the PRAGMA).

In the "by name" mode, the output of the resulting data schema uses the following rules:

- The resulting table includes all columns that were found in at least one of the input tables.
- If a column wasn't present in all the input tables, then it's automatically assigned the optional data type (that can accept `NULL`).
- If a column in different input tables had different types, then the shared type (the broadest one) is output.
- If a column in different input tables had a heterogeneous type, for example, string and numeric, an error is raised.

The order of output columns in this mode is equal to the largest common prefix of the order of inputs, followed by all other columns in the alphabetic order.
If the largest common prefix is empty (for example, if the order isn't specified for one of the inputs), then the output order is undefined.

In the "by position" mode, the output of the resulting data schema uses the following rules:

- All inputs must have equal number of columns
- The order of columns must be defined for all inputs
- The names of the resulting columns must match the names of columns in the first table
- The type of the resulting columns is output as a common (widest) type of input column types having the same positions

The order of the output columns in this mode is the same as the order of columns in the first input.

Examples

```
SELECT 1 AS x
UNION ALL
SELECT 2 AS y
UNION ALL
SELECT 3 AS z;
```

In the default mode, this query returns a selection with three columns x, y, and z. When `PRAGMA PositionalUnionAll;` is enabled, the selection only includes the x column.

```
PRAGMA PositionalUnionAll;

SELECT 1 AS x, 2 as y
UNION ALL
SELECT * FROM AS_TABLE([<|x:3, y:4|>]); -- error: the order of columns in AS_TABLE is undefined
```

VIEW (INDEX)

To make a `SELECT` by secondary index of row-oriented table statement, use the following:

```
SELECT *
    FROM TableName VIEW IndexName
    WHERE …
```

> **Warning**
>
> Supported only for row-oriented tables. Support for column-oriented tables is currently under development.

Examples

- Select all the fields from the `series` row-oriented table using the `views_index` index with the `views >=someValue` criteria:

  ```
  SELECT series_id, title, info, release_date, views, uploaded_user_id
      FROM series VIEW views_index
      WHERE views >= someValue
  ```

- `JOIN` the `series` and `users` row-oriented tables on the `userName` field using the `users_index` and `name_index` indexes, respectively:

  ```
  SELECT t1.series_id, t1.title
      FROM series VIEW users_index AS t1
      INNER JOIN users VIEW name_index AS t2
      ON t1.uploaded_user_id == t2.user_id
      WHERE t2.name == userName;
  ```

VIEW (Vector index)

To select data from a row-oriented table using a vector index, use the following statements:

```
PRAGMA ydb.KMeansTreeSearchTopSize = "10";

SELECT ...
    FROM TableName VIEW IndexName
    WHERE ...
    ORDER BY Knn::SomeDistance(...)
    LIMIT ...
```

```
PRAGMA ydb.KMeansTreeSearchTopSize = "10";

SELECT ...
    FROM TableName VIEW IndexName
    WHERE ...
    ORDER BY Knn::SomeSimilarity(...) DESC
    LIMIT ...
```

Principles of operation and settings of the vector index are described in detail in Vector Indexes.

Note

A vector index supports a distance or similarity function from the Knn extension specified during its construction.

A vector index isn't automatically selected by the optimizer and must be specified explicitly using the `VIEW IndexName` expression.

If the `VIEW` expression is not used, the query will perform a full table scan with pairwise comparison of vectors. It is recommended to check the optimality of the written query using query plan analysis. In particular, ensure there is no full scan of the main table.

Warning

Indexed vector search completeness or performance may decrease after updating a large amount of data in a table with a vector index. For more details, see Updating Vector Indexes.

KMeansTreeSearchTopSize

Indexed vector search is based on an approximate algorithm (ANN, Approximate Nearest Neighbors). That means that indexed search may produce a result that differs from a similar full-scan nearest neighbor search.

Completeness of the indexed vector search is controlled by the following parameter: `PRAGMA ydb.KMeansTreeSearchTopSize`.

This parameter controls the maximum number of scanned clusters nearest to the requested search vector at every level of the search tree.
The parameter should be set explicitly for every search query.

The default value is 1. This means that only one nearest cluster is scanned at every level of the search tree by default. This parameter value maximizes search performance but results in minimum possible recall. To increase search recall (at the expense of slightly reduced search performance), you should increase the PRAGMA value, for example:

```
PRAGMA ydb.KMeansTreeSearchTopSize="10";

SELECT *
    FROM TableName VIEW IndexName
    ORDER BY Knn::CosineDistance(embedding, $target)
    LIMIT 10
```

Examples

- Select all the fields from the `series` row-oriented table using the `views_index` vector index created for `embedding` and cosine similarity:

  ```
  PRAGMA ydb.KMeansTreeSearchTopSize="10";
  SELECT series_id, title, info, release_date, views, uploaded_user_id, Knn::CosineSimilarity(embedding,
  $target) as similarity
      FROM series VIEW views_index
      ORDER BY similarity DESC
      LIMIT 10
  ```

- Select all the fields from the `series` row-oriented table using the `views_filtered_index` filtered vector index created for `embedding` and optimized for efficient filtering by `release_date`:

  ```
  PRAGMA ydb.KMeansTreeSearchTopSize="10";
  SELECT series_id, title, info, release_date, views, uploaded_user_id, Knn::CosineSimilarity(embedding,
  $target) as similarity
      FROM series VIEW views_filtered_index
      WHERE release_date = "2025-03-31"
      ORDER BY similarity DESC
      LIMIT 10
  ```

VIEW (Fulltext index)

To select data from a row-oriented table using a fulltext index, use the `VIEW` expression:

```
SELECT ...
FROM TableName VIEW IndexName
WHERE FulltextMatch(TextColumn, "query")
ORDER BY ...
```

Note

A fulltext index isn't automatically selected by the optimizer and must be specified explicitly using `VIEW IndexName`.

Fulltext search functions (`FulltextMatch`, `FulltextScore`) require `VIEW`. If `VIEW` isn't used, the query fails.

Only one fulltext predicate is supported per read through `VIEW`. `FulltextMatch` / `FulltextScore` can't be used under `OR` or `NOT`.
For relevance access, you must include `FulltextScore(...) > 0` in `WHERE`.

For function details, see Fulltext search, including
FulltextMatch and
FulltextScore.

FulltextMatch

FulltextMatch(text, query) filters rows by whether the text matches the fulltext query:

```
SELECT id, title
FROM articles VIEW ft_idx
WHERE FulltextMatch(body, "machine learning")
LIMIT 20;
```

Only the first two arguments can be positional. Additional parameters must be passed as **named arguments**:

- `Mode` (String): query mode:
  - `Keywords` (default) — the query is split into individual terms; how they are combined is determined by `DefaultOperator`
  - `Query` — extended syntax with logical operators: required terms via `+`, excluded terms via `-`, exact phrases in double quotes
  - `Wildcard` — wildcard search: `%` matches any substring, `_` matches a single character (similar to `LIKE`); requires an n-gram index
- `DefaultOperator` (String): term combination operator in `Keywords` mode:
  - `And` (default) — all query terms must be present in the text
  - `Or` — terms split into **required** (prefixed with `+`, must appear in every result) and **optional** (no prefix, count toward `MinimumShouldMatch`). Without any `+` prefix, all terms are optional and at least one must match (see example)
- `MinimumShouldMatch` (String): minimum number of **optional** terms that must match when `DefaultOperator = "Or"` — specified as an absolute number (for example, `"3"`) or a percentage of the optional terms (for example, `"50%"`). Required (`+`) terms are not counted

`Wildcard` mode and `%` / `_` patterns (requires n-grams)

If the index is created with n-gram filtering, you can use `%` and `_` patterns similar to `LIKE`.
To explicitly enable this behavior, pass `"Wildcard" AS Mode` as a named argument:

```
SELECT id, title
FROM articles VIEW ft_idx
WHERE FulltextMatch(body, "mach% learn%", "Wildcard" AS Mode)
LIMIT 20;
```

LIKE / ILIKE (use the fulltext index)

For fulltext indexes with n-grams, `LIKE` / `ILIKE` predicates over the indexed text column use the same logic as `FulltextMatch(..., "Wildcard" AS Mode)`:

```
SELECT id, title
FROM articles VIEW ft_idx
WHERE body ILIKE "%learn%ing%"
LIMIT 20;
```

FulltextScore (BM25 relevance)

FulltextScore(text, query) returns a relevance score and can be used for ranking.
Relevance scoring requires the fulltext_relevance index type.

```
SELECT id, title, FulltextScore(body, "machine learning") AS relevance
FROM articles VIEW ft_idx
WHERE FulltextScore(body, "machine learning") > 0
ORDER BY relevance DESC
LIMIT 10;
```

Optional parameters

Additional parameters must be passed as **named arguments**:

- `DefaultOperator` (String): term combination operator — `And` (default, all terms must be present) or `Or` (terms split into **required** with `+` prefix and **optional** without; at least `MinimumShouldMatch` optional terms must match, and every required term must be present)
- `MinimumShouldMatch` (String): when `DefaultOperator = "Or"`, minimum number of **optional** terms that must match — specified as an absolute number (for example, `"2"`) or a percentage of the optional terms (for example, `"50%"`). Required (`+`) terms are not counted
- `K1` (Double): term frequency saturation parameter in BM25 — controls how strongly repeated occurrences of a term affect the score; typical range: 1.2–2.0
- `B` (Double): document length normalization parameter in BM25 — `0.0` disables normalization, `1.0` fully normalizes by document length; typical value: 0.75

Example:

```
SELECT id, FulltextScore(body, "machine learning", "Or" AS DefaultOperator, "50%" AS MinimumShouldMatch) AS r
elevance
FROM articles VIEW ft_idx
WHERE FulltextScore(body, "machine learning", "Or" AS DefaultOperator, "50%" AS MinimumShouldMatch) > 0
ORDER BY relevance DESC;
```

Note

Only the first two arguments of `FulltextMatch` / `FulltextScore` can be positional. Use named arguments for all additional parameters.

The `FulltextScore(...)` expression is repeated in full in both `SELECT` and `WHERE` — YQL, like standard SQL, evaluates `WHERE` before `SELECT`, so aliases defined in `SELECT` are not available in `WHERE`. Both occurrences must be identical.

VIEW (JSON index)

To execute a `SELECT` query on a row table with explicit use of a JSON index, use the `VIEW` expression:

```
SELECT ...
FROM documents VIEW json_idx
WHERE <предикат на основе JSON_EXISTS / JSON_VALUE>
ORDER BY ...
```

In the query example above, `documents` is the name of the table containing a column of type `Json` or `JsonDocument`, and `json_idx` is the name of the JSON index created on that column.

If the predicate is not supported for execution via a JSON index, a query with an explicit `VIEW` expression fails with a compile-time error. Without the `VIEW` expression, the optimizer cannot select this index for such a predicate, and the query will be executed by another method (for example, selecting a different index or performing a full scan of the base table).

Note

A JSON index can be selected automatically by the optimizer if the predicate meets the requirements for index usage. For debugging and guaranteed index usage, specify it explicitly using `VIEW IndexName`.

For a description of supported predicates, see the Supported predicates section.

Automatic index selection

If the `WHERE` predicate contains `JSON_EXISTS` / `JSON_VALUE` calls on an indexed JSON column, the optimizer may use the JSON index without an explicit `VIEW`. Automatic selection follows these rules:

- The JSON index is considered by the optimizer with the lowest priority — it is a fallback option that is selected only after other access methods have been ruled out.
- The JSON index is not selected if the query can already be served by a primary key or another, more specific secondary index.
- Explicit specification of `VIEW` overrides the optimizer's decision and forces index usage.
- All indexed subexpressions in a single query must refer to the same indexed JSON column. If predicates on different indexed columns are combined via `AND` / `OR`, automatic selection is not applied.

Note

Automatic JSON index selection is rule-based: it uses the query structure and schema metadata, without data statistics. The selection logic may change in future versions of YDB, so for guaranteed index usage, specify it explicitly via `VIEW`.

JSON_EXISTS

JSON_EXISTS(doc, jsonpath) checks for the existence of a path or value inside a JSON document:

```
SELECT id, payload
FROM documents VIEW json_idx
WHERE JSON_EXISTS(payload, '$.user.id');
```

The JSON index supports almost all JsonPath syntax, except for nested predicates and boolean expressions at the context object level (`$`) in `JSON_EXISTS`. A more complex example of a supported expression:

```
SELECT id, payload
FROM documents VIEW json_idx
WHERE JSON_EXISTS(payload, '$.user ? (@.id > 100)');
```

JSON_VALUE

JSON_VALUE(doc, jsonpath RETURNING) extracts a scalar value by a JsonPath and returns it in the specified type. To use the JSON index, the `RETURNING <type>` clause is required:

```
SELECT id, payload
FROM documents VIEW json_idx
WHERE JSON_VALUE(payload, '$.user.name' RETURNING Utf8) = "Charlie"u;
```

When checking equality conditions or whether a value is in a given list (`IN`), the index search is performed by the 'path + value' token, which provides the highest selectivity. For other comparisons (`!=` , `<` , `>=` , `BETWEEN` , etc.), only the path token is used, and the final comparison accuracy is ensured by a post-filter.

Parameters

Three ways to pass query parameters are supported:

1. Direct comparison of the `JSON_VALUE` result with a parameter:

   ```
   DECLARE $id AS Int64;
   SELECT * FROM documents VIEW json_idx
   WHERE JSON_VALUE(payload, '$.owner_id' RETURNING Int64) = $id;
   ```

2. Checking whether the result is in a list of values:

```
DECLARE $tags AS List<Utf8>;
SELECT * FROM documents VIEW json_idx
WHERE JSON_VALUE(payload, '$.tag' RETURNING Utf8) IN $tags;
```

3. Passing a parameter to JsonPath via the `PASSING` clause:

```
DECLARE $v AS Int64;
SELECT * FROM documents VIEW json_idx
WHERE JSON_EXISTS(payload, '$.k ? (@ == $v)' PASSING $v AS v);
```

AND and OR combinations

`JSON_EXISTS` and `JSON_VALUE` on the same JSON column can be combined in a single `WHERE` using the `AND` and `OR` operators:

```
SELECT id, payload
FROM documents VIEW json_idx
WHERE JSON_VALUE(payload, '$.user.name' RETURNING Utf8) = "Charlie"u
  AND JSON_VALUE(payload, '$.user.id' RETURNING Int64) BETWEEN 100 AND 200;
```

Note

Query execution via a JSON index can only use a subset of expressions based on `JSON_EXISTS` and `JSON_VALUE` (see Supported predicates). Conditions that do not fall under these rules (for example, negations, comparisons with another column, comparison of two `JSON_VALUE` from different columns) are not indexed; in `AND` they go into a post-filter, in `OR` they lead to rejection of index usage for the entire group of conditions combined via `OR`.

Hybrid search (HybridRank)

Hybrid search fuses fulltext and vector ranking into a single result. A hybrid query is a `SELECT` over the base table whose `ORDER BY` key is a single `HybridRank` call:

```
PRAGMA ydb.KMeansTreeSearchTopSize = "10";

$queryText = "machine learning";
$queryVector = Knn::ToBinaryStringFloat([0.1, 0.2, 0.3, 0.4]);

SELECT id, title
FROM documents
ORDER BY HybridRank(
    FullTextScore(text, $queryText),
    Knn::CosineDistance(embedding, $queryVector))
LIMIT 10;
```

> **Note**
>
> A hybrid query reads through the base table and does **not** use `VIEW IndexName`: each branch's index is resolved from the corresponding `HybridRank` argument.
>
> The query requires both a fulltext_relevance index over the column passed to `FullTextScore` and a (non-prefixed) vector_kmeans_tree index over the column passed to `Knn`. The recall of the vector branch is controlled by KMeansTreeSearchTopSize.

HybridRank

The general form of the function:

```
HybridRank(
    score1, score2 [, ... scoreN]        -- 2+ scoring expressions: FullTextScore(...) or Knn::<Distance|Simi
larity>(...)
    [, "rrf" | "linear"  AS Mode]        -- fusion method (default "rrf")
    [, (w1, w2, ...)     AS Weights]     -- per-branch weights (default 1.0 each)
    [, k                 AS K]           -- RRF constant (default 60.0)
    [, true | false      AS Normalize]   -- "linear" mode only: min-max normalize (default true)
    [, (idx1, idx2, ...) AS Indexes]     -- per-branch index names (default: auto-detect)
    [, (lim1, lim2, ...) AS Limits]      -- per-branch candidate-pool sizes (default: LIMIT * 10)
    [, ($x) -> {...}     AS RankLambda]  -- custom fusion over per-branch ranks (replaces built-in Mode)
    [, ($x) -> {...}     AS ScoreLambda] -- custom fusion over per-branch raw scores (replaces built-in Mode)
)
```

`HybridRank` may only appear as the entire sort key of an `ORDER BY` clause. It takes **two or more scoring expressions** (positional), followed by optional **named arguments**.

Each scoring expression is one *branch* of the fusion, classified by its form:

- a FullTextScore(text, query) expression — a **fulltext** branch, resolved against a `fulltext_relevance` index over the `text` column;
- a Knn distance or similarity over a column (for example `Knn::CosineDistance(embedding, $queryVector)` or `Knn::CosineSimilarity(embedding, $queryVector)`) — a **vector** branch, resolved against a `vector_kmeans_tree` index over that column.

The argument order is not significant, and there may be more than two branches (for example a fulltext branch plus two vector branches). Each branch retrieves its own candidate pool and contributes one term to every document's fused score.

Fusion modes

Two fusion methods are available via the `Mode` argument:

- `rrf` (default) — Reciprocal Rank Fusion. Each branch contributes `weight / (K + rank)`, where `rank` is the document's position within that branch. Because RRF uses ranks rather than raw scores, the (non-comparable) magnitudes of the branch scores do not matter.
- `linear` — a weighted sum of the per-branch scores: `weight * score` summed over branches. By default the per-branch scores are min-max normalized to `[0, 1]` before summing; set `Normalize` to `false` to fuse the raw scores.

In both modes a document that is absent from a branch's candidate pool simply does not receive that branch's contribution.

Custom fusion lambda

Instead of the built-in `Mode` (`rrf` / `linear`), you can supply a custom fusion lambda that computes the fused score from the per-branch values yourself. Two mutually exclusive lambda kinds are available:

- `RankLambda` — the lambda receives the document's per-branch ranks as a `Dict<Int64, Int64>` (branch index → 1-based rank within that branch). A branch the document is absent from has no entry, so `$ranks[i]` is `NULL`.
- `ScoreLambda` — the lambda receives the document's per-branch raw scores as a `Dict<Int64, Double>` (branch index → the branch's score value: the fulltext relevance, or the vector distance/similarity). A branch the document is absent from has no entry, so `$scores[i]` is `NULL`.

The lambda takes a single argument (the dict) and must return a numeric value (`Double` is recommended); larger values rank higher. The lambda replaces the built-in fusion, so it cannot be combined with `Mode`, `Weights`, `K`, or `Normalize` — fold any weights and constants into the lambda body.

```
SELECT id, title
FROM documents
ORDER BY HybridRank(
    FullTextScore(text, $queryText),
    Knn::CosineDistance(embedding, $queryVector),
    ($ranks) -> {
        RETURN 1.0 / (60 + COALESCE($ranks[0], 100000))
             + 1.0 / (60 + COALESCE($ranks[1], 100000));
    } AS RankLambda)
LIMIT 10;
```

Named arguments

All optional parameters are passed as named arguments. The `Weights`, `Limits`, and `Indexes` arguments are tuples positionally parallel to the scoring expressions — they must have exactly one entry per branch.

Argument	Type	Description
`Mode`	String	Fusion method: `"rrf"` (default) or `"linear"`. Case-insensitive (`"RRF"` / `"Linear"` are accepted).
`Weights`	Tuple of numbers	Per-branch weight, one per scoring argument. Default `1.0` for every branch. A weight of `0` disables a branch.
`K`	Double	The RRF constant (`rrf` mode only). Default `60.0`. Larger values flatten the influence of top ranks.
`Normalize`	Bool	`linear` mode only. When `true` (default), per-branch scores are min-max normalized before summing; when `false`, raw scores are fused.
`Indexes`	Tuple of strings	Explicit index name per branch, overriding auto-detection. Required when a branch's column is covered by more than one matching index.
`Limits`	Tuple of positive integers	Explicit candidate-pool size per branch. By default each branch retrieves `LIMIT * HybridSearchFactor` (factor default `10`) candidates.
`RankLambda`	Lambda	Custom fusion over per-branch ranks. The lambda receives a `Dict<Int64, Int64>` (branch index → 1-based rank; absent branches have no entry) and returns a numeric score. Replaces the built-in `Mode`; cannot be combined with `Mode`, `Weights`, `K`, or `Normalize`.
`ScoreLambda`	Lambda	Custom fusion over per-branch raw scores. The lambda receives a `Dict<Int64, Double>` (branch index → raw branch score; absent branches have no entry) and returns a numeric score. Replaces the built-in `Mode`; cannot be combined with `Mode`, `Weights`, `K`, or `Normalize`.

Examples

Weighted RRF — bias the ranking toward the vector branch:

```
$queryText = "machine learning";
$queryVector = Knn::ToBinaryStringFloat([0.1, 0.2, 0.3, 0.4]);

SELECT id, title
FROM documents
ORDER BY HybridRank(
    FullTextScore(text, $queryText),
    Knn::CosineDistance(embedding, $queryVector),
    (1, 2) AS Weights)
LIMIT 10;
```

Three-branch RRF — combine text relevance with two vector branches over different embedding columns:

```
$queryText = "machine learning";
$titleVector = Knn::ToBinaryStringFloat([0.1, 0.2, 0.3, 0.4]);
$bodyVector = Knn::ToBinaryStringFloat([0.7, 0.8, 0.9, 1.0]);

SELECT id, title
FROM documents
ORDER BY HybridRank(
    FullTextScore(text, $queryText),
    Knn::CosineDistance(title_embedding, $titleVector),
    Knn::CosineDistance(body_embedding, $bodyVector),
    (1, 2, 3) AS Weights)
LIMIT 10;
```

Linear fusion over normalized scores:

```
$queryText = "machine learning";
$queryVector = Knn::ToBinaryStringFloat([0.1, 0.2, 0.3, 0.4]);

SELECT id, title
FROM documents
ORDER BY HybridRank(
    FullTextScore(text, $queryText),
    Knn::CosineDistance(embedding, $queryVector),
    "linear" AS Mode)
LIMIT 10;
```

Explicit index names and candidate-pool sizes. Because the per-branch pool sizes are given by `Limits`, the query's own `LIMIT` no longer needs to be a literal and may be a parameter:

```
DECLARE $limit AS Uint64;

$queryText = "machine learning";
$queryVector = Knn::ToBinaryStringFloat([0.1, 0.2, 0.3, 0.4]);

SELECT id, title
FROM documents
ORDER BY HybridRank(
    FullTextScore(text, $queryText),
    Knn::CosineDistance(embedding, $queryVector),
    ("ft_idx", "vec_idx") AS Indexes,
    (100, 200) AS Limits)
LIMIT $limit;
```

Custom `RankLambda` — spell out RRF by hand, weighting the vector branch 100× more than the text branch:

```
$queryText = "machine learning";
$queryVector = Knn::ToBinaryStringFloat([0.1, 0.2, 0.3, 0.4]);

SELECT id, title
FROM documents
ORDER BY HybridRank(
    FullTextScore(text, $queryText),
    Knn::CosineDistance(embedding, $queryVector),
    ($ranks) -> {
        RETURN   1.0 / (60 + COALESCE($ranks[0], 100000))
             + 100.0 / (60 + COALESCE($ranks[1], 100000));
    } AS RankLambda)
LIMIT 10;
```

Custom `ScoreLambda` — combine the raw fulltext relevance and the negated vector distance (closer = larger score):

```
$queryText = "machine learning";
$queryVector = Knn::ToBinaryStringFloat([0.1, 0.2, 0.3, 0.4]);

SELECT id, title
FROM documents
ORDER BY HybridRank(
    FullTextScore(text, $queryText),
    Knn::CosineDistance(embedding, $queryVector),
    ($scores) -> {
        RETURN COALESCE($scores[0], 0.0) - COALESCE($scores[1], 1000000.0);
    } AS ScoreLambda)
LIMIT 10;
```

Limitations

- `HybridRank(...)` must be the entire `ORDER BY` key; it cannot be negated, nested in a larger expression, or combined with other sort keys.
- At least two scoring arguments are required — a single branch is not a hybrid query.
- `LIMIT` must be a literal (it sizes the per-branch candidate pools). Use an explicit `AS Limits` to allow a parameterized `LIMIT`.
- A custom fusion lambda (`RankLambda` or `ScoreLambda`) replaces the built-in fusion and cannot be combined with `Mode`, `Weights`, `K`, or `Normalize`. At most one of `RankLambda` or `ScoreLambda` may be specified.
- Prefixed vector indexes are not supported yet.

WITH

Specified after the data source in `FROM` and used to provide additional hints for table usage. Hints cannot be specified for subqueries and named expressions.

The following values are supported:

- `INFER_SCHEMA` — sets the flag for inferring the table schema. The behavior is similar to setting the yt.InferSchema pragma, but only for a specific data source. You can specify the number of rows to infer (a number from 1 to 1000).
- `FORCE_INFER_SCHEMA` — sets the flag for forcing schema inference of the table. The behavior is similar to setting the yt.ForceInferSchema pragma, but only for a specific data source. You can specify the number of rows to infer (a number from 1 to 1000).
- `DIRECT_READ` — suppresses the operation of some optimizers and forces the table contents to be used as is. The behavior is similar to setting the debug DirectRead pragma, but only for a specific data source.
- `INLINE` — indicates that the table contents are small and should be processed using an in-memory representation. The actual table size is not checked, and if it is large, the query may fail due to memory exhaustion.
- `UNORDERED` — suppresses the use of the table's original sorting.
- `XLOCK` — indicates that an exclusive lock should be taken on the table. Useful when the table is read during the query metaprogram processing stage and then its contents are updated in the main query. It helps avoid data loss if an external process modifies the table between the execution of the metaprogram phase and the main part of the query.
- `SCHEMA` type — indicates that the specified table schema should be used entirely, ignoring the schema in the metadata.
- `COLUMNS` type — indicates that the specified types should be used for columns whose names match the column names in the table metadata, as well as which additional columns are present in the table.
- `IGNORETYPEV3`, `IGNORE_TYPE_V3` — sets the flag to ignore type_v3 types in the table. The behavior is similar to setting the yt.IgnoreTypeV3 pragma, but only for a specific data source.

When working with external file data sources, you can additionally specify a number of parameters:

- `FORMAT`: data storage format in file storages in federated queries. Allowed values: `csv_with_names`, `tsv_with_names`, `json_list`, `json_each_row`, `json_as_string`, `parquet`, `raw`.
- `COMPRESSION`: file compression format in file storages in federated queries. Valid values: gzip, zstd, lz4, brotli, bzip2, xz.
- `PARTITIONED_BY` - a list of partitioning columns of data in file storages in federated queries. Contains a list of columns in the order they are placed in the file storage.
- `projection.enabled` - a flag for enabling extended data partitioning. Valid values: `true`, `false`.
- `projection.<field_name>.type` - field type of extended data partitioning. Valid values: `integer`, `enum`, `date`.
- `projection.<field_name>.<options>` - extended properties of the field of extended data partitioning.

When reading from a topic in streaming queries, you can specify watermarks parameters:

- `WATERMARK` — expression for calculating the watermark. Currently, only the write time to a topic with a constant delay is supported. Format: `__ydb_write_time - Interval("<delay>")`, where `<delay>` is specified in ISO 8601 format.
- `WATERMARK_GRANULARITY` — watermark generation frequency. The smaller it is, the higher the CPU consumption by the query and the lower the response latency. Only relevant for streaming queries. Specified in ISO 8601 format. Default value — 1 second.
- `WATERMARK_IDLE_TIMEOUT` — period after which an idle partition will be excluded from the combined watermark calculation. Only relevant for streaming queries. Specified in ISO 8601 format. Default value — 5 seconds.

When specifying hints `SCHEMA` and `COLUMNS`, the type value must be a structure type.

Examples

```
SELECT key FROM my_table WITH INFER_SCHEMA;
SELECT key FROM my_table WITH FORCE_INFER_SCHEMA="42";
```

```
$s = (SELECT COUNT(*) FROM my_table WITH XLOCK);

INSERT INTO my_table WITH TRUNCATE
SELECT EvaluateExpr($s) AS a;
```

```
SELECT key, value FROM my_table WITH SCHEMA Struct<key:String, value:Int32>;
```

```
SELECT key, value FROM my_table WITH COLUMNS Struct<value:Int32?>;
```

```
SELECT key, value FROM EACH($my_tables) WITH SCHEMA Struct<key:String, value:List<Int32>>;
```

```
SELECT
    *
FROM
    my_topic
WITH (
    FORMAT = json_each_row,
    SCHEMA = (
        ts String
    ),
    WATERMARK = __ydb_write_time - Interval("PT5S"),
    WATERMARK_GRANULARITY = "PT1S",
    WATERMARK_IDLE_TIMEOUT = "PT5S"
);
```

WITHOUT

Excluding columns from the result of `SELECT *`.

Examples

```
SELECT * WITHOUT foo, bar FROM my_table;
```

```
PRAGMA simplecolumns;
SELECT * WITHOUT t.foo FROM my_table AS t
CROSS JOIN (SELECT 1 AS foo) AS v;
```

WHERE

Filtering rows in the `SELECT` result based on a condition in row-oriented or column-oriented.

Example

```
SELECT key FROM my_table
WHERE value > 0;
```

Warning

Correlated subqueries in `WHERE` are not supported: a subquery cannot refer to columns or table aliases from an outer query. To select rows that have matching rows in another table, use `LEFT SEMI JOIN`. To select rows without matches, use `LEFT ONLY JOIN`.

ORDER BY

Sorting the `SELECT` result using a comma-separated list of sorting criteria. As a criteria, you can use a column value or an expression on columns. Ordering by column sequence number is not supported (`ORDER BY N` where `N` is a number).

Each criteria can be followed by the sorting direction:

- `ASC` : Sorting in the ascending order. Applied by default.
- `DESC` : Sorting in the descending order.

Multiple sorting criteria will be applied left-to-right.

Example

```
SELECT key, string_column
FROM my_table
ORDER BY key DESC, LENGTH(string_column) ASC;
```

You can also use `ORDER BY` for window functions.

ASSUME ORDER BY

Checking that the `SELECT` result is sorted by the value in the specified column or multiple columns. The result of such a `SELECT` statement is treated as sorted, but without actually running a sort. Sort check is performed at the query execution stage.

As in case of `ORDER BY`, it supports setting the sort order using the keywords `ASC` (ascending order) and `DESC` (descending order). Expressions are not supported in `ASSUME ORDER BY`.

Examples

```
SELECT key || "suffix" as key, -CAST(subkey as Int32) as subkey
FROM my_table
ASSUME ORDER BY key, subkey DESC;
```

LIMIT and OFFSET

`LIMIT`: limits the output to the specified number of rows. By default, the output is not restricted.

`OFFSET`: specifies the offset from the beginning (in rows). By default, it's zero.

Examples

```
SELECT key FROM my_table
LIMIT 7;
```

```
SELECT key FROM my_table
LIMIT 7 OFFSET 3;
```

```
SELECT key FROM my_table
LIMIT 3, 7; -- equivalent to the previous example
```

TABLESAMPLE and SAMPLE

> **Warning**
>
> Supported only for row-oriented tables. Support for column-oriented tables is currently under development.

Building a random sample from the data source specified in `FROM`.

`TABLESAMPLE` is part of the SQL standard and works as follows:

- The operating mode is specified:
  - `BERNOULLI` means "slowly, straightforwardly going through all the data, but in a truly random way".
  - `SYSTEM` uses knowledge about the physical data storage of data to avoid full data scans, but somewhat sacrificing randomness of the sample.

The data is split into sufficiently large blocks, and the whole data blocks are sampled. For applied calculations on sufficiently large tables, the result may well be consistent.

- The size of the random sample is indicated as a percentage after the operating mode, in parentheses.
- To manage the block size in the `SYSTEM` mode, use the `yt.SamplingIoBlockSize` pragma.
- Optionally, it can be followed by the `REPEATABLE` keyword and an integer in parentheses to be used as a seed for a pseudorandom number generator.

`SAMPLE` is a shorter alias without sophisticated settings and sample size specified as a fraction. It currently corresponds to the `BERNOULLI` mode.

> **Note**
>
> In the `BERNOULLI` mode, if the `REPEATABLE` keyword is added, the seed is mixed with the chunk ID for each chunk in the table. That's why sampling from different tables with the same content might produce different results.

Examples

```
SELECT *
FROM my_table
TABLESAMPLE BERNOULLI(1.0) REPEATABLE(123); -- one percent of the table
```

```
SELECT *
FROM my_table
TABLESAMPLE SYSTEM(1.0); -- about one percent of the table
```

```
SELECT *
FROM my_table
SAMPLE 1.0 / 3; -- one-third of the table
```

MATCH_RECOGNIZE

The `MATCH_RECOGNIZE` expression performs pattern recognition in a sequence of rows and returns the found results. This functionality is important for various business areas, such as fraud detection, pricing analysis in finance, and sensor data processing. This area is known as Complex Event Processing (CEP), and pattern recognition is a valuable tool for this. An example of how `MATCH_RECOGNIZE` works is provided in the link.

Data processing algorithm

The `MATCH_RECOGNIZE` expression performs the following actions:

1. The input table is divided into non-overlapping groups. Each group consists of a set of rows from the input table with identical values in the columns listed after `PARTITION BY`.
2. Each group is ordered according to the `ORDER BY` clause.
3. Recognition of pattern from `PATTERN` is performed independently in each ordered group.
4. Pattern search in the sequence of rows is a step-by-step process: rows are checked one by one if they fit the pattern. Among all matches starting in the earliest row, the one consisting of the largest number of rows is selected. If no matches were found starting in the earliest row, the search continues starting from the next row.
5. After a match is found, the columns defined by expressions in the `MEASURES` block are calculated.
6. Depending on the `ROWS PER MATCH` mode, one or all rows for the found match are output.
7. The `AFTER MATCH SKIP` mode determines from which row the pattern recognition will resume.

Syntax

```
MATCH_RECOGNIZE (
    [ PARTITION BY <partition_1> [ ... , <partition_N> ] ]
    [ ORDER BY <sort_key_1> [ ... , <sort_key_N> ] ]
    [ MEASURES <expression_1> AS <column_name_1> [ ... , <expression_N> AS <column_name_N> ] ]
    [ ROWS PER MATCH ]
    [ AFTER MATCH SKIP ]
    PATTERN (<search_pattern>)
    DEFINE <variable_1> AS <predicate_1> [ ... , <variable_N> AS <predicate_N> ]
)
```

Here is a brief description of the SQL syntax elements of the `MATCH_RECOGNIZE` expression:

- `DEFINE`: Block for declaring variables that describe the search pattern and the conditions that rows must meet for each variable.
- `PATTERN`: Regular expressions describing the search pattern.
- `MEASURES`: Defines the list of columns for the returned data. Each column is specified by an SQL expression for its computation.
- `ROWS PER MATCH`: Determines the structure of the returned data and the number of rows for each match found.
- `AFTER MATCH SKIP`: Defines the method of moving to the point of the next match search.
- `ORDER BY`: Determines sorting of input data. Pattern search is performed within the data sorted according to the list of columns or expressions listed in `<sort_key_1> [ ... , <sort_key_N> ]`.
- `PARTITION BY`: Divides the input table according to the specified rules in accordance with `<partition_1> [ ... , <partition_N> ]`. Pattern search is performed independently in each part.

DEFINE

```
DEFINE <variable_1> AS <predicate_1> [ ... , <variable_N> AS <predicate_N> ]
```

`DEFINE` declares variables that are used to describe the desired pattern defined in `PATTERN`. Variables are named SQL statements evaluated over the input data. The syntax of the SQL statements in `DEFINE` is the same as the SQL statements of the `WHERE` predicate. For example, the `button = 1` expression searches for rows with the value `1` in the `button` column. Any SQL expressions that can be used to perform a search, including aggregation functions (`LAST`, `FIRST`). For example, `button > 2 AND zone_id < 12` or `LAST(button) > 10`.

In the example below, the SQL statement `A.button = 1` is declared as variable `A`.

```
DEFINE
    A AS A.button = 1
```

> **Note**
>
> `DEFINE` does not currently support aggregation functions (e.g., `AVG`, `MIN`, or `MAX`) and `PREV` and `NEXT` functions.

When processing each row of data, all SQL statements describing variables in `DEFINE` are calculated. When the SQL-expression describing the corresponding variable from `DEFINE` gets the `TRUE` value, such a row is labeled with the `DEFINE` variable name and added to the list of rows subject to pattern matching.

Example

When defining variables in SQL expressions, you can reference other variables:

```
DEFINE
    A AS A.button = 1 AND LAST(A.zone_id) = 12,
    B AS B.button = 2 AND FIRST(A.zone_id) = 12
```

An input data row will be computed as variable `A` if it contains a `button` column with value `1` and the last row of the set of previously matched `A` has a `zone_id` column with value `12`. The row will be computed as variable `B` if the data row contains a `button` column with value `2` and the first row of the set of previously matched variables `A` has a `zone_id` column with value `12`.

PATTERN

```
PATTERN (<search_pattern>)
```

The `PATTERN` keyword describes the search pattern in the format derived from variables in the `DEFINE` section. The `PATTERN` syntax is similar to the one of regular expressions.

> **Warning**
>
> If a variable used in the `PATTERN` section has not been previously described in the `DEFINE` section, it is assumed that it is always `TRUE`.

You can use quantifiers in `PATTERN`. In regular expressions, they determine the number of repetitions of an element or subsequence in the matched pattern. Here is the list of supported quantifiers:

Quantifier	Description
`A+`	One or more occurrences of `A`
`A*`	Zero or more occurrences of `A`
`A?`	Zero or one occurrence of `A`
`B{n}`	Exactly `n` occurrences of `B`
`C{n, m}`	From `n` to `m` occurrences of `C`
`D{n,}`	At least `n` occurrences of `D`
`(A|B)`	Occurrence of `A` or `B` in the data
`(A|B){,m}`	From zero to `m` occurrences of `A` or `B`

Supported pattern search sequences:

Supported sequences	Syntax	Description
Sequence	`A B+ C+ D+`	The system searches for the exact specified sequence, the occurrence of other variables within the sequence is not allowed. The pattern search is performed in the order of the pattern variables.
One of	`A | B | C`	Variables are listed in any order with a pipe | between them. The search is performed for any variable from the specified list.
Grouping	`(A | B)+ | C`	Variables inside round brackets are considered a single group. In this case, quantifiers apply to the entire group.
Exclusion from result	`{- A B+ C -}`	Rows found by the pattern in parentheses will be excluded from the result in `ALL ROWS PER MATCH` mode

Example

```
PATTERN (B1 E* B2+ B3)
DEFINE
    B1 as B1.button = 1,
    B2 as B2.button = 2,
    B3 as B3.button = 3
```

The `DEFINE` section describes the `B1`, `B2`, and `B3` variables, while it does not describe `E`. Such notation allows interpreting `E` as any event, so the following pattern will be searched: one `button 1` click, one or more `button 2` clicks, and one `button 3` click. Meanwhile, between a click of `button 1` and `button 2`, any number of any other events may occur.

MEASURES

```
MEASURES <expression_1> AS <column_name_1> [ ... , <expression_N> AS <column_name_N> ]
```

`MEASURES` describes the set of returned columns when a pattern is found. A set of returned columns should be represented by an SQL expression with the aggregate functions over the variables declared in the `DEFINE` statement.

Example

The input data for the example are:

ts	button	device_id	zone_id
100	1	3	0
200	1	3	1
300	2	2	0
400	3	1	1

```
MEASURES
    AGGREGATE_LIST(B1.zone_id * 10 + B1.device_id) AS ids,
    COUNT(DISTINCT B1.zone_id) AS count_zones,
    LAST(B3.ts) - FIRST(B1.ts) AS time_diff,
    42 AS meaning_of_life
PATTERN (B1+ B2 B3)
DEFINE
    B1 AS B1.button = 1,
    B2 AS B2.button = 2,
    B3 AS B3.button = 3
```

Result:

ids	count_zones	time_diff	meaning_of_life
[3,13]	2	300	42

The `ids` column contains the list of `zone_id * 10 + device_id` values counted among the rows matched with the `B1` variable. The `count_zones` column contains the number of unique values of the `zone_id` column among the rows matched with the `B1` variable. Column `time_diff` contains the difference between the value of column `ts` in the last row of the set of rows matched with variable `B3` and the value of column `ts` in the first row of the set of rows matched with variable `B1`. The `meaning_of_life` column contains the constant `42`. Thus, an expression in `MEASURES` may contain aggregate functions over multiple variables, but there must be only one variable within a single aggregate function.

ROWS PER MATCH

`ROWS PER MATCH` determines the number of result rows for each match found, as well as the number of columns returned. The default mode is `ONE ROW PER MATCH`.

`ONE ROW PER MATCH` sets the `ROWS PER MATCH` mode to output one row for the match found. The structure of the returned data corresponds to the columns listed in `PARTITION BY` and `MEASURES`.

`ALL ROWS PER MATCH` sets the `ROWS PER MATCH` mode to output all rows of the match found except explicitly excluded by parentheses. In addition to the columns of the source table, the structure of the returned data includes the columns listed in the `MEASURES`.

Examples

The input data for all examples are:

ts	button
100	1
200	2
300	3

Example 1

```
MEASURES
    FIRST(B1.ts) AS first_ts,
    FIRST(B2.ts) AS mid_ts,
    LAST(B3.ts) AS last_ts
ONE ROW PER MATCH
PATTERN (B1 {- B2 -} B3)
DEFINE
    B1 AS B1.button = 1,
    B2 AS B2.button = 2,
    B3 AS B3.button = 3
```

Result:

first_ts	mid_ts	last_ts
100	200	300

Example 2

```
MEASURES
    FIRST(B1.ts) AS first_ts,
    FIRST(B2.ts) AS mid_ts,
    LAST(B3.ts) AS last_ts
ALL ROWS PER MATCH
PATTERN (B1 {- B2 -} B3)
DEFINE
    B1 AS B1.button = 1,
    B2 AS B2.button = 2,
    B3 AS B3.button = 3
```

Result:

first_ts	mid_ts	last_ts	button	ts
100	200	300	1	100
100	200	300	3	300

AFTER MATCH SKIP

`AFTER MATCH SKIP` determines the method of transitioning from the found match to searching for the next one. In the `AFTER MATCH SKIP TO NEXT ROW` mode, the search for the next match starts after the first row of the previous one, while in the `AFTER MATCH SKIP PAST LAST ROW` mode it starts after the last row of the previous match. The default mode is `PAST LAST ROW`.

Examples

The input data for all examples are:

ts	button
100	1
200	1
300	2
400	3

Example 1

```
MEASURES
    FIRST(B1.ts) AS first_ts,
    LAST(B3.ts) AS last_ts
AFTER MATCH SKIP TO NEXT ROW
PATTERN (B1+ B2 B3)
DEFINE
    B1 AS B1.button = 1,
    B2 AS B2.button = 2,
    B3 AS B3.button = 3
```

Result:

first_ts	last_ts
100	400
200	400

Example 2

```
MEASURES
    FIRST(B1.ts) AS first_ts,
    LAST(B3.ts) AS last_ts
AFTER MATCH SKIP PAST LAST ROW
PATTERN (B1+ B2 B3)
DEFINE
    B1 AS B1.button = 1,
    B2 AS B2.button = 2,
    B3 AS B3.button = 3
```

Result:

first_ts	last_ts
100	400

ORDER BY

```
ORDER BY <sort_key_1> [ ... , <sort_key_N> ]

<sort_key> ::= { <column_names> | <expression> }
```

`ORDER BY` determines sorting of the input data. That is, before all pattern search operations are performed, the data will be pre-sorted according to the specified keys or expressions. The syntax is similar to the `ORDER BY` SQL expression.

Example

```
ORDER BY CAST(ts AS Timestamp)
```

PARTITION BY

```
PARTITION BY <partition_1> [ ... , <partition_N> ]

<partition> ::= { <column_names> | <expression> }
```

`PARTITION BY` partitions the source data into multiple non-overlapping groups, each used for an independent pattern search. If the expression is not specified, all data is processed as a single group. Records with the same values of the columns listed after `PARTITION BY` fall into the same group.

Example

```
PARTITION BY device_id, zone_id
```

Limitations

Our support for the `MATCH_RECOGNIZE` expression will eventually comply with SQL-2016; currently, however, the following limitations apply:

- `MEASURES`. Functions `PREV` / `NEXT` are not supported.
- `AFTER MATCH SKIP`. Only the `AFTER MATCH SKIP TO NEXT ROW` and `AFTER MATCH SKIP PAST LAST ROW` modes are supported.
- `PATTERN`. Union pattern variables are not implemented.
- `DEFINE`. Aggregation functions are not supported.

Example of usage

Here is a hands-on example of pattern recognizing in a data table produced by an IoT device, where pressing its buttons triggers certain events. Let's assume you need to find and process the following sequence of button clicks: `button 1`, `button 2`, and `button 3`.

The structure of the data to transmit is as follows:

ts	button	device_id	zone_id
600	3	17	3
500	3	4	2
400	2	17	3
300	2	4	2
200	1	17	3
100	1	4	2

The body of the SQL query looks like this:

```
PRAGMA FeatureR010="prototype"; -- pragma for enabling MATCH_RECOGNIZE

SELECT * FROM input MATCH_RECOGNIZE ( -- Performing pattern matching from input
    PARTITION BY device_id, zone_id -- Partitioning the input data into groups by columns device_id and zone_
id
    ORDER BY ts -- Viewing events based on the ts column data sorted ascending
    MEASURES
        LAST(B1.ts) AS b1, -- Going to get the latest timestamp of clicking button 1 in the query results
        LAST(B3.ts) AS b3  -- Going to get the latest timestamp of clicking button 3 in the query results
    ONE ROW PER MATCH             -- Going to get one result row per match hit
    AFTER MATCH SKIP TO NEXT ROW -- Going to move to the next row once the match is found
    PATTERN (B1 B2+ B3) -- Searching for a pattern that includes one button 1 click, one or more button 2 cli
cks, and one button 3 click
    DEFINE
        B1 AS B1.button = 1, -- Defining the B1 variable as event of clicking button 1 (the button field equa
ls 1)
        B2 AS B2.button = 2, -- Defining the B2 variable as event of clicking button 2 (the button field equa
ls 2)
        B3 AS B3.button = 3  -- Defining the B3 variable as event of clicking button 3 (the button field equa
ls 3)
);
```

Result:

b1	b3	device_id	zone_id
100	500	4	2
200	600	17	3

Streaming read from a topic

You can read data from a topic using a regular `SELECT` without creating a streaming query. To do this, specify `STREAMING = "TRUE"` in the `WITH` block and set a limit on the number of output rows via `LIMIT`; otherwise, the query will not complete.

Warning

This method is intended only for debugging and checking data in a topic. For production processes, create streaming queries using CREATE STREAMING QUERY.

Note

In the examples:

- `ext_source` is a pre-created external data source
- `input_topic` is a local or external topic.

For more information, see local and external topics.

Example

```
SELECT
    Data
FROM
    ext_source.input_topic -- or local topic input_topic
WITH (
    FORMAT = raw,
    SCHEMA = (
        Data String
    ),
    STREAMING = "TRUE"
)
LIMIT 1
```

See also

- Debug reads from a topic — recipe with additional examples
- Streaming queries
- CREATE STREAMING QUERY

SHOW CREATE

`SHOW CREATE` returns a query required to recreate the structure of the specified object: a table or view. The returned query may contain multiple DDL statements.

Syntax

```
SHOW CREATE [TABLE|VIEW] <name>;
```

Parameters

- `TABLE|VIEW` — The object type. Valid values are `TABLE` or `VIEW`.
- `<name>` — The object name. An absolute path may also be specified.

Result

The command always returns **exactly one row** with three columns:

Path	PathType	CreateQuery
Path	Table/View	DDL statements for creation

- **Path** — The path to the object (for example, `MyTable` or `MyView`).
- **PathType** — The type of object: `Table` or `View`.
- **CreateQuery** — The complete set of DDL statements needed to create the object:
  - For tables: the main CREATE TABLE statement (with the path relative to the database root), plus any additional statements describing the current configuration, such as:
    - ALTER TABLE ... ALTER INDEX — for index partitioning settings.
    - ALTER TABLE ... ADD CHANGEFEED — for adding a changefeed.
    - `ALTER SEQUENCE` — for restoring a `Sequence` state for `Serial` columns.
  - For views: the definition via CREATE VIEW, and, if necessary, the statements the view has captured from the creation context, for example, PRAGMA TablePathPrefix.

Examples

Row-oriented tables

```
SHOW CREATE TABLE my_table;
```

Path	PathType	CreateQuery
`my_table`	`Table`	`CREATE TABLE...` — see below

```
CREATE TABLE `my_table` (
    `Key1` Uint32 NOT NULL,
    `Key2` Utf8 NOT NULL,
    `Key3` Serial4 NOT NULL,
    `Value1` Utf8 FAMILY `my_family`,
    `Value2` Bool,
    `Value3` String,
    INDEX `my_index` GLOBAL SYNC ON (`Key2`, `Value1`, `Value2`),
    FAMILY `my_family` (COMPRESSION = 'lz4'),
    PRIMARY KEY (`Key1`, `Key2`, `Key3`)
)
WITH (
    AUTO_PARTITIONING_BY_SIZE = ENABLED,
    AUTO_PARTITIONING_PARTITION_SIZE_MB = 1000
);

ALTER TABLE `my_table`
    ADD CHANGEFEED `feed_3` WITH (MODE = 'KEYS_ONLY', FORMAT = 'JSON', RETENTION_PERIOD = INTERVAL('PT30M'),
TOPIC_MIN_ACTIVE_PARTITIONS = 3)
;

ALTER SEQUENCE `/Root/my_table/_serial_column_Key3` START WITH 101 INCREMENT BY 404 RESTART;

ALTER TABLE `my_table`
    ALTER INDEX `my_index` SET (AUTO_PARTITIONING_BY_LOAD = ENABLED, AUTO_PARTITIONING_MIN_PARTITIONS_COUNT =
1000, AUTO_PARTITIONING_MAX_PARTITIONS_COUNT = 5000)
;
```

Column-oriented tables

```
SHOW CREATE TABLE my_table;
```

Path	PathType	CreateQuery
`my_table`	`Table`	`CREATE TABLE...` — see below

```
CREATE TABLE `my_table` (
    `Key1` Uint64 NOT NULL,
    `Key2` Utf8 NOT NULL,
    `Key3` Int32 NOT NULL,
    `Value1` Utf8,
    `Value2` Int16,
    `Value3` String,
    PRIMARY KEY (`Key1`, `Key2`, `Key3`)
)
PARTITION BY HASH (`Key1`, `Key2`)
WITH (
    STORE = COLUMN,
    AUTO_PARTITIONING_MIN_PARTITIONS_COUNT = 100,
    TTL =
        INTERVAL('PT10S') TO EXTERNAL DATA SOURCE `/Root/tier1`,
        INTERVAL('PT1H') DELETE
    ON Key1 AS SECONDS
);
```

Views

```
SHOW CREATE VIEW my_view;
```

Path	PathType	CreateQuery
`my_view`	`View`	`PRAGMA TablePathPrefix...` — see below

```
PRAGMA TablePathPrefix = '/Root/DirA/DirB/DirC';

CREATE VIEW `my_view` WITH (security_invoker = TRUE) AS
SELECT
    *
FROM
    test_table
;
```

TRUNCATE TABLE

`TRUNCATE TABLE` removes all user data from the specified table and its indexes.

Syntax

```
TRUNCATE TABLE <table_name>;
```

Limitations

- Supported only for row-oriented tables.
- While the operation runs, the table is locked for reads and writes.
- The operation cannot be interrupted or canceled after it has started.
- The operation cannot be performed if the table has:
  - an asynchronous secondary index,
  - a changefeed,
  - asynchronous replication.

Examples

Removes all data from the table with the full path `/Root/test/my_table`.

```
TRUNCATE TABLE `/Root/test/my_table`;
```

Removes all data from table `my_table` in the current database.

```
TRUNCATE TABLE `my_table`;
```

- ALTER TABLE
- DROP TABLE

UPDATE

> **Warning**
>
> Currently, mixing column-oriented tables and row-oriented tables in a single transaction is supported only if the transaction performs read operations; no writes are allowed. Support for read-write transactions involving both table types is under development.
>
> If a write transaction includes both types of tables, it fails with the following error: `Write transactions that use both row-oriented and column-oriented tables are disabled at current time`.

Updates the data in the table. After the `SET` keyword, enter the columns where you want to update values and the new values themselves. The list of rows is defined by the `WHERE` clause. If `WHERE` is omitted, the updates are applied to all the rows of the table.

`UPDATE` can't change the value of the primary key columns.

Example

```
UPDATE my_table
SET Value1 = YQL::ToString(Value2 + 1), Value2 = Value2 - 1
WHERE Key1 > 1;
```

UPDATE ON

Updates the data in the table based on the results of a subquery. The set of columns returned by the subquery must be a subset of the table's columns being updated, and all columns of the table's primary key must be present in the returned columns. The data types of the columns returned by the subquery must match the data types of the corresponding columns in the table.

The primary key value is used to search for the rows being updated. For each row found, the values of the non-key columns is replaced with the values returned in the corresponding row of the result of the subquery. The values of the table columns that are missing in the returned columns of the subquery remain unchanged.

Example

```
$to_update = (
    SELECT Key, SubKey, "Updated" AS Value FROM my_table
    WHERE Key = 1
);

UPDATE my_table ON
SELECT * FROM $to_update;
```

UPDATE ... RETURNING

Updates rows and returns their new values in a single operation. It allows to retrieve information about the updated rows in one query, eliminating the need for an additional SELECT statement.

Examples

- Return all values of modified rows

```
UPDATE orders
SET status = 'shipped'
WHERE order_date < '2023-01-01'
RETURNING *;
```

- Return specific columns

```
UPDATE products
SET price = price * 0.9
WHERE category = 'Electronics'
RETURNING product_id, name, price AS new_price;
```

- BATCH UPDATE

UPSERT INTO

> **Warning**
>
> Currently, mixing column-oriented tables and row-oriented tables in a single transaction is supported only if the transaction performs read operations; no writes are allowed. Support for read-write transactions involving both table types is under development.
>
> If a write transaction includes both types of tables, it fails with the following error: `Write transactions that use both row-oriented and column-oriented tables are disabled at current time`.

UPSERT (which stands for UPDATE or INSERT) updates or inserts multiple rows to a table based on a comparison by the primary key. Missing rows are added. For the existing rows, the values of the specified columns are updated, but the values of the other columns are preserved.

`UPSERT` and `REPLACE` are data modification operations that don't require a prefetch and run faster and cheaper than other operations because of that.

Column mapping when using `UPSERT INTO ... SELECT` is done by names. Use `AS` to fetch a column with the desired name in `SELECT`.

Examples

```
UPSERT INTO my_table
SELECT pk_column, data_column1, col24 as data_column3 FROM other_table
```

```
UPSERT INTO my_table ( pk_column1, pk_column2, data_column2, data_column5 )
VALUES ( 1, 10, 'Some text', Date('2021-10-07')),
       ( 2, 10, 'Some text', Date('2021-10-08'))
```

UPSERT INTO ... RETURNING

Inserts or updates a row and returns their values in a single operation. It allows to retrieve information about the affected row in one query, eliminating the need for an additional SELECT statement.

Examples

- Return all values of modified row

```
UPSERT INTO orders (order_id, status, amount)
VALUES (1001, 'shipped', 500)
RETURNING *;
```

- Return specific columns

```
UPSERT INTO users (user_id, name, email)
VALUES (42, 'John Doe', 'john@example.com')
RETURNING user_id, email;
```

UPSERT OBJECT (TYPE SECRET)

> **Warning**
>
> The syntax for managing secrets will change in future YDB releases.

To change the contents of a secret, use the following statement:

```
UPSERT OBJECT `secret_name` (TYPE SECRET) WITH value = `secret_value`;
```

Where:

- `secret_name` — Name of the secret.
- `secret_value` — Secret payload.

Example

The following statement sets the secret named `MySecretName` to `MySecretData`:

```
UPSERT OBJECT `MySecretName` (TYPE SECRET) WITH value = `MySecretData`;
```

Basic VALUES syntax in YQL

VALUES as a top-level operator

It lets you create a table from specified values. For example, this statement creates a table of k columns and n rows:

```
VALUES (expr_11, expr_12, ..., expr_1k),
       (expr_21, expr_22, ..., expr_2k),
       ....
       (expr_n1, expr_n2, ..., expr_nk);
```

This statement is totally equivalent to the following one:

```
SELECT expr_11, expr_12, ..., expr_1k UNION ALL
SELECT expr_21, expr_22, ..., expr_2k UNION ALL
....
SELECT expr_n1, expr_n2, ..., expr_nk;
```

Example

```
VALUES (1,2), (3,4);
```

VALUES after FROM

VALUES can also be used in a subquery, after FROM. For example, the following two queries are equivalent:

```
VALUES (1,2), (3,4);
SELECT * FROM (VALUES (1,2), (3,4));
```

In all the examples above, column names are assigned by YQL and have the format `column0 ... columnN`. To assign arbitrary column names, you can use the following construct:

```
SELECT * FROM (VALUES (1,2), (3,4)) as t(x,y);
```

In this case, the columns will get the names `x`, `y`.

Built-in YQL functions

- Basic
- Aggregate
- Window
- For lists
- For dictionaries
- For structures
- For types
- For code generation
- For JSON
- C++ libraries

Basic built-in functions

Below are the general-purpose functions. For specialized functions, there are separate articles: aggregate functions, window functions, and functions for lists, dictionaries, structures, data types, and code generation.

COALESCE

Iterates through the arguments from left to right and returns the first non-empty argument found. To be sure that the result is non-empty (not of an optional type), the rightmost argument must be of this type (often a literal is used for this). With a single argument, returns this argument unchanged.

Lets you pass potentially empty values to functions that can't handle them by themselves.

A short format using the low-priority `??` operator is available (lower than the Boolean operations). You can use the `NVL` alias.

Examples

```
SELECT COALESCE(
  maybe_empty_column,
  "it's empty!"
) FROM my_table;
```

```
SELECT
  maybe_empty_column ?? "it's empty!"
FROM my_table;
```

```
SELECT NVL(
  maybe_empty_column,
  "it's empty!"
) FROM my_table;
```

All three examples above are equivalent.

LENGTH

Returns the length of the string in bytes. This function is also available under the `LEN` name .

Examples

```
SELECT LENGTH("foo");
```

```
SELECT LEN("bar");
```

> **Note**
>
> To calculate the length of a string in Unicode characters, you can use the function Unicode::GetLength.
>
> To get the number of elements in the list, use the function ListLength.

SUBSTRING

Returns a substring.

Required arguments:

- Source string;
- Position: The offset from the beginning of the string in bytes (integer) or `NULL` meaning "from the beginning".

Optional arguments:

- Substring length: The number of bytes starting from the specified position (an integer, or the default `NULL` meaning "up to the end of the source string").

Indexing starts from zero. If the specified position and length are beyond the string, returns an empty string.
If the input string is optional, the result is also optional.

Examples

```
SELECT SUBSTRING("abcdefg", 3, 1); -- d
```

```
SELECT SUBSTRING("abcdefg", 3); -- defg
```

```
SELECT SUBSTRING("abcdefg", NULL, 3); -- abc
```

FIND

Finding the position of a substring in a string.

Required arguments:

- Source string;
- The substring being searched for.

Optional arguments:

- A position in bytes to start the search with (an integer or `NULL` by default that means "from the beginning of the source string").

Returns the first substring position found or `NULL` (meaning that the desired substring hasn't been found starting from the specified position).

Examples

```
SELECT FIND("abcdefg_abcdefg", "abc"); -- 0
```

```
SELECT FIND("abcdefg_abcdefg", "abc", 1); -- 8
```

```
SELECT FIND("abcdefg_abcdefg", "abc", 9); -- null
```

RFIND

Reverse finding the position of a substring in a string, from the end to the beginning.

Required arguments:

- Source string;
- The substring being searched for.

Optional arguments:

- A position in bytes to start the search with (an integer or `NULL` by default, meaning "from the end of the source string").

Returns the first substring position found or `NULL` (meaning that the desired substring hasn't been found starting from the specified position).

Examples

```
SELECT RFIND("abcdefg_abcdefg", "bcd"); -- 9
```

```
SELECT RFIND("abcdefg_abcdefg", "bcd", 8); -- 1
```

```
SELECT RFIND("abcdefg_abcdefg", "bcd", 0); -- null
```

StartsWith, EndsWith

Checking for a prefix or suffix in a string.

Required arguments:

- Source string;
- The substring being searched for.

The arguments can be of the `String` or `Utf8` type and can be optional.

Examples

```
SELECT StartsWith("abc_efg", "abc") AND EndsWith("abc_efg", "efg"); -- true
```

```
SELECT StartsWith("abc_efg", "efg") OR EndsWith("abc_efg", "abc"); -- false
```

```
SELECT StartsWith("abcd", NULL); -- null
```

```
SELECT EndsWith(NULL, Utf8("")); -- null
```

IF

Checks the condition: `IF(condition_expression, then_expression, else_expression)`.

It's a simplified alternative for CASE WHEN ... THEN ... ELSE ... END.

You may omit the `else_expression` argument. In this case, if the condition is false (`condition_expression` returned `false`), an empty value is returned with the type corresponding to `then_expression` and allowing for `NULL`. Hence, the result will have an optional data type.

Examples

```
SELECT
  IF(foo > 0, bar, baz) AS bar_or_baz,
  IF(foo > 0, foo) AS only_positive_foo
FROM my_table;
```

NANVL

Replaces the values of `NaN` (not a number) in expressions like `Float`, `Double`, or Optional.

Arguments:

1. The expression where you want to make a replacement.
2. The value to replace `NaN`.

If one of the arguments is `Double`, the result is `Double`, otherwise, it's `Float`. If one of the arguments is `Optional`, then the result is `Optional`.

Examples

```
SELECT
  NANVL(double_column, 0.0)
FROM my_table;
```

Random...

Generates a pseudorandom number:

- `Random()`: A floating point number (Double) from 0 to 1.
- `RandomNumber()`: An integer from the complete Uint64 range.
- `RandomUuid()`: Uuid version 4.

Signatures

```
Random(T1[, T2, ...])->Double
RandomNumber(T1[, T2, ...])->Uint64
RandomUuid(T1[, T2, ...])->Uuid
```

No arguments are used for random number generation: they are only needed to control the time of the call. A new random number is returned at each call. Therefore:

- If Random is called again within a **same query** and with a same set of arguments does not guarantee getting the same sets of random numbers. The values will be equal if the Random calls fall into the same execution phase.
- Calling of Random with the same set of arguments in **different queries** returns different sets of random numbers.

> **Warning**
>
> If Random is used in named expressions, its one-time calculation is not guaranteed. Depending on the optimizers and runtime environment, it can be counted both once and multiple times. To make sure it's only counted once, materialize a named expression into a table.

Use cases:

- `SELECT RANDOM(1);`: Get one random value for the entire query and use it multiple times (to get multiple random values, you can pass various constants of any type).
- `SELECT RANDOM(1) FROM table;`: The same random number for each row in the table.
- `SELECT RANDOM(1), RANDOM(2) FROM table;`: Two random numbers for each row of the table, all the numbers in each of the columns are the same.
- `SELECT RANDOM(some_column) FROM table;`: Different random numbers for each row in the table.
- `SELECT RANDOM(some_column), RANDOM(some_column) FROM table;`: Different random numbers for each row of the table, but two identical numbers within the same row.
- `SELECT RANDOM(some_column), RANDOM(some_column + 1) FROM table;` or `SELECT RANDOM(some_column), RANDOM(other_column) FROM table;`: Two columns, with different numbers in both.

Examples

```
SELECT
    Random(key) -- [0, 1)
FROM my_table;
```

```
SELECT
    RandomNumber(key) -- [0, Max<Uint64>)
FROM my_table;
```

```
SELECT
    RandomUuid(key) -- Uuid version 4
FROM my_table;
```

```
SELECT
    RANDOM(column) AS rand1,
    RANDOM(column) AS rand2, -- same as rand1
    RANDOM(column, 1) AS randAnd1, -- different from rand1/2
    RANDOM(column, 2) AS randAnd2 -- different from randAnd1
FROM my_table;
```

CurrentUtc...

`CurrentUtcDate()`, `CurrentUtcDatetime()` and `CurrentUtcTimestamp()`: Getting the current date and/or time in UTC. The result data type is specified at the end of the function name.

The arguments are optional and work same as RANDOM.

Examples

```
SELECT CurrentUtcDate();
```

```
SELECT CurrentUtcTimestamp(TableRow()) FROM my_table;
```

CurrentTz...

`CurrentTzDate()`, `CurrentTzDatetime()`, and `CurrentTzTimestamp()`: Get the current date and/or time in the IANA time zone specified in the first argument. The result data type is specified at the end of the function name.

The arguments that follow are optional and work same as RANDOM.

Examples

```
SELECT CurrentTzDate("Europe/Moscow");
```

```
SELECT CurrentTzTimestamp("Europe/Moscow", TableRow()) FROM my_table;
```

AddTimezone

Adding the time zone information to the date/time in UTC. In the result of `SELECT` or after `CAST`, a `String` will be subject to the time zone rules used to calculate the time offset.

Arguments:

1. Date: the type is `Date` / `Datetime` / `Timestamp`.
2. The IANA name of the time zone.

Result type: `TzDate` / `TzDatetime` / `TzTimestamp`, depending on the input data type.

Examples

```
SELECT AddTimezone(Datetime("2018-02-01T12:00:00Z"), "Europe/Moscow");
```

RemoveTimezone

Removing the time zone data and converting the value to date/time in UTC.

Arguments:

1. Date: the type is `TzDate` / `TzDatetime` / `TzTimestamp`.

Result type: `Date` / `Datetime` / `Timestamp`, depending on the input data type.

Examples

```
SELECT RemoveTimezone(TzDatetime("2018-02-01T12:00:00,Europe/Moscow"));
```

Version

`Version()` returns a string describing the current version of the node processing the request. In some cases, such as during rolling upgrades, it might return different strings depending on which node processes the request. It does not accept any arguments.

Examples

```
SELECT Version();
```

MAX_OF, MIN_OF, GREATEST, and LEAST

Returns the minimum or maximum among N arguments. Those functions let you replace the SQL standard statement `CASE WHEN a < b THEN a ELSE b END` that would be too sophisticated for N more than two.

The argument types must be mutually castable and accept `NULL`.

`GREATEST` is a synonym for `MAX_OF` and `LEAST` is a synonym for `MIN_OF`.

Examples

```
SELECT MIN_OF(1, 2, 3);
```

AsTuple, AsStruct, AsList, AsDict, AsSet, AsListStrict, AsDictStrict and AsSetStrict

Creates containers of the applicable types. For container literals, operator notation is also supported.

Specifics:

- The container elements are passed in arguments. Hence, the number of elements in the resulting container is equal to the number of arguments passed, except when the dictionary keys repeat.
- `AsTuple` and `AsStruct` can be called without arguments, and also the arguments can have different types.
- The field names in `AsStruct` are set using `AsStruct(field_value AS field_name)`.
- Creating a list requires at least one argument if you need to output the element types. To create an empty list with the given type of elements, use the function ListCreate. You can create an empty list as an `AsList()` call without arguments. In this case, this

expression will have the `EmptyList` type.

- Creating a dictionary requires at least one argument if you need to output the element types. To create an empty dictionary with the given type of elements, use the function DictCreate. You can create an empty dictionary as an `AsDict()` call without arguments, in this case, this expression will have the `EmptyDict` type.
- Creating a set requires at least one argument if you need to output element types. To create an empty set with the given type of elements, use the function SetCreate. You can create an empty set as an `AsSet()` call without arguments, in this case, this expression will have the `EmptySet` type.
- `AsList` outputs the common type of elements in the list. A type error is raised in the case of incompatible types.
- `AsDict` separately outputs the common types for keys and values. A type error is raised in the case of incompatible types.
- `AsSet` outputs common types for keys. A type error is raised in the case of incompatible types.
- `AsListStrict`, `AsDictStrict`, `AsSetStrict` require the same type for their arguments.
- `AsDict` and `AsDictStrict` expect `Tuple` of two elements as arguments (key and value, respectively). If the keys repeat, only the value for the first key remains in the dictionary.
- `AsSet` and `AsSetStrict` expect keys as arguments.

Examples

```
SELECT
  AsTuple(1, 2, "3") AS `tuple`,
  AsStruct(
    1 AS a,
    2 AS b,
    "3" AS c
  ) AS `struct`,
  AsList(1, 2, 3) AS `list`,
  AsDict(
    AsTuple("a", 1),
    AsTuple("b", 2),
    AsTuple("c", 3)
  ) AS `dict`,
  AsSet(1, 2, 3) AS `set`
```

Container literals

Some containers support operator notation for their literal values:

- Tuple: `(value1, value2...)`;
- Structure: `<|name1: value1, name2: value2...|>`;
- List: `[value1, value2,...]`;
- Dictionary: `{key1: value1, key2: value2...}`;
- Set: `{key1, key2...}`.

In every case, you can use an insignificant trailing comma. For a tuple with one element, this comma is required: `(value1,)`.
For field names in the structure literal, you can use an expression that can be calculated at evaluation time, for example, string literals or identifiers (including those enclosed in backticks).

For nested lists, use AsList, for nested dictionaries, use AsDict, for nested sets, use AsSet, for nested tuples, use AsTuple, for nested structures, use AsStruct.

Examples

```
$name = "computed " || "member name";
SELECT
  (1, 2, "3") AS `tuple`,
  <|
    `complex member name`: 2.3,
    b: 2,
    $name: "3",
    "inline " || "computed member name": false
  |> AS `struct`,
  [1, 2, 3] AS `list`,
  {
    "a": 1,
    "b": 2,
    "c": 3,
  } AS `dict`,
  {1, 2, 3} AS `set`
```

Variant

`Variant()` creates a variant value over a tuple or structure.

Arguments:

- Value
- String with a field name or tuple index
- Variant type

Example

```
$var_type = Variant<foo: Int32, bar: Bool>;

SELECT
   Variant(6, "foo", $var_type) as Variant1Value,
   Variant(false, "bar", $var_type) as Variant2Value;
```

AsVariant

`AsVariant()` creates a value of a variant over a structure including one field. This value can be implicitly converted to any variant over a structure that has a matching data type for this field name and might include more fields with other names.

Arguments:

- Value
- A string with the field name

Example

```
SELECT
   AsVariant(6, "foo") as VariantValue
```

Visit, VisitOrDefault

Processes the possible values of a variant over a structure or tuple using the provided handler functions for each field/element of the variant.

Signature

```
Visit(Variant<key1: K1, key2: K2, ...>, K1->R AS key1, K2->R AS key2, ...)->R
Visit(Variant<K1, K2, ...>, K1->R, K2->R, ...)->R

VisitOrDefault(Variant<K1, K2, ...>{Flags:AutoMap}, R, [K1->R, [K2->R, ...]])->R
VisitOrDefault(Variant<key1: K1, key2: K2, ...>{Flags:AutoMap}, R, [K1->R AS key1, [K2->R AS key2, ...]])->R
```

Arguments

- For a variant over structure: accepts the variant as the positional argument and named arguments (handlers) corresponding to each field of the variant.
- For a variant over tuple: accepts the variant and handlers for each element of the variant as positional arguments.
- `VisitOrDefault` includes an additional positional argument (on the second place) for the default value, enabling the omission of certain handlers.

Example

```
$vartype = Variant<num: Int32, flag: Bool, str: String>;
$handle_num = ($x) -> { return 2 * $x; };
$handle_flag = ($x) -> { return If($x, 200, 10); };
$handle_str = ($x) -> { return Unwrap(CAST(LENGTH($x) AS Int32)); };

$visitor = ($var) -> { return Visit($var, $handle_num AS num, $handle_flag AS flag, $handle_str AS str); };
SELECT
    $visitor(Variant(5, "num", $vartype)),               -- 10
    $visitor(Just(Variant(True, "flag", $vartype))),     -- Just(200)
    $visitor(Just(Variant("somestr", "str", $vartype))), -- Just(7)
    $visitor(Nothing(OptionalType($vartype))),           -- Nothing(Optional<Int32>)
    $visitor(NULL)                                       -- NULL
;
```

VariantItem

Returns the value of a homogeneous variant (i.e., a variant containing fields/elements of the same type).

Signature

```
VariantItem(Variant<key1: K, key2: K, ...>{Flags:AutoMap})->K
VariantItem(Variant<K, K, ...>{Flags:AutoMap})->K
```

Example

```
$vartype1 = Variant<num1: Int32, num2: Int32, num3: Int32>;
SELECT
    VariantItem(Variant(7, "num2", $vartype1)),          -- 7
    VariantItem(Just(Variant(5, "num1", $vartype1))),    -- Just(5)
    VariantItem(Nothing(OptionalType($vartype1))),       -- Nothing(Optional<Int32>)
    VariantItem(NULL)                                    -- NULL
;
```

Way

Returns an active field (active index) of a variant over a struct (tuple).

Signature

```
Way(Variant<key1: K1, key2: K2, ...>{Flags:AutoMap})->Utf8
Way(Variant<K1, K2, ...>{Flags:AutoMap})->Uint32
```

Example

```
$vr = Variant(1, "0", Variant<Int32, String>);
$vrs = Variant(1, "a", Variant<a:Int32, b:String>);
SELECT Way($vr);  -- 0
SELECT Way($vrs); -- "a"
```

DynamicVariant

Creates a homogeneous variant instance (i.e. containing fields/elements of the same type), where the variant index or field can be set dynamically. If the index or field name does not exist, `NULL` will be returned.
The inverse function is VariantItem.

Signature

```
DynamicVariant(item:T,index:Uint32?,Variant<T, T, ...>)->Optional<Variant<T, T, ...>>
DynamicVariant(item:T,index:Utf8?,Variant<key1: T, key2: T, ...>)->Optional<Variant<key1: T, key2: T, ...>>
```

Example

```
$dt = Int32;
$tvt = Variant<$dt,$dt>;
SELECT ListMap([(10,0u),(20,2u),(30,NULL)],($x)->(DynamicVariant($x.0,$x.1,$tvt))); -- [0: 10,NULL,NULL]

$dt = Int32;
$svt = Variant<x:$dt,y:$dt>;
SELECT ListMap([(10,'x'u),(20,'z'u),(30,NULL)],($x)->(DynamicVariant($x.0,$x.1,$svt))); -- [x: 10,NULL,NULL]
```

Enum

`Enum()` creates an enumeration value.

Arguments:

- A string with the field name
- Enumeration type

Example

```
$enum_type = Enum<Foo, Bar>;
SELECT
   Enum("Foo", $enum_type) as Enum1Value,
   Enum("Bar", $enum_type) as Enum2Value;
```

AsEnum

`AsEnum()` creates a value of enumeration including one element. This value can be implicitly cast to any enumeration containing such a name.

Arguments:

- A string with the name of an enumeration item

Example

```
SELECT
   AsEnum("Foo");
```

AsTagged, Untag

Wraps the value in the Tagged data type with the specified tag, preserving the physical data type. `Untag`: The reverse operation.

Required arguments:

1. Value of any type.
2. Tag name.

Returns a copy of the value from the first argument with the specified tag in the data type.

Examples of use cases:

- Returns to the client's web interface the media files from BASE64-encoded strings.
- Additional refinements at the level of returned columns types.

TableRow, JoinTableRow

Getting the entire table row as a structure. No arguments. `JoinTableRow` in case of `JOIN` always returns a structure with table prefixes.

Example

```
SELECT TableRow() FROM my_table;
```

Ensure...

Checking for the user conditions:

- `Ensure()`: Checking whether the predicate is true at query execution.
- `EnsureType()`: Checking that the expression type exactly matches the specified type.
- `EnsureConvertibleTo()`: A soft check of the expression type (with the same rules as for implicit type conversion).

If the check fails, the entire query fails.

Arguments:

1. An expression that will result from a function call if the check is successful. It's also checked for the data type in the corresponding functions.
2. Ensure uses a Boolean predicate that is checked for being `true`. The other functions use the data type that can be obtained using the relevant functions, or a string literal with a text description of the type.
3. An optional string with an error comment to be included in the overall error message when the query is complete. The data itself can't be used for type checks, since the data check is performed at query validation (or can be an arbitrary expression in the case of Ensure).

Examples

```
SELECT Ensure(
    value,
    value < 100,
    "value out or range"
) AS value FROM my_table;
```

```
SELECT EnsureType(
    value,
    TypeOf(other_value),
    "expected value and other_value to be of same type"
) AS value FROM my_table;
```

```
SELECT EnsureConvertibleTo(
    value,
    Double?,
    "expected value to be numeric"
) AS value FROM my_table;
```

EvaluateExpr, EvaluateAtom

Evaluate an expression before the start of the main calculation and input its result to the query as a literal (constant). In many contexts, where only a constant would be expected in standard SQL (for example, in table names, in the number of rows in LIMIT, and so on), this functionality is implicitly enabled automatically.

EvaluateExpr can be used where the grammar already expects an expression. For example, you can use it to:

- Round the current time to days, weeks, or months and insert it into the query to ensure correct query caching, although usually when functions are used to get the current time, query caching is completely disabled.
- Run a heavy calculation with a small result once per query instead of once per job.

The only argument for both functions is the expression for calculation and substitution.

Restrictions:

- The expression must not trigger MapReduce operations.
- This functionality is fully locked in YQL over YDB.

Examples

```
$now = CurrentUtcDate();
SELECT EvaluateExpr(
    DateTime::MakeDate(DateTime::StartOfWeek($now)
    )
);
```

Literals of primitive types

For primitive types, you can create literals based on string literals.

Syntax

`<Primitive type>( <string>[, <additional attributes>] )`

Unlike `CAST("myString" AS MyType)`:

- The check for literal's castability to the desired type occurs at validation.
- The result is non-optional.

The `<string>` argument must be a string literal. Expressions, including variables, columns, query parameters, and function results, are not supported. To convert a value at query execution time, use `CAST(expression AS <Primitive type>)`. For example, convert a computed `String` to `Uuid` using `CAST(expression AS Uuid)`, not `Uuid(expression)`.

```
$uuid = Uuid("550e8400-e29b-41d4-a716-446655440000");
$uuidAsString = CAST($uuid AS String);

SELECT CAST($uuidAsString AS Uuid) = $uuid; -- true
```

For the data types `Date`, `Datetime`, `Timestamp`, and `Interval`, literals are supported only in the format corresponding to ISO 8601. `Interval` has the following differences from the standard:

- It supports the negative sign for shifts to the past.
- Microseconds can be expressed as fractional parts of seconds.
- You can't use units of measurement exceeding one week.
- The options with the beginning/end of the interval and with repetitions, are not supported.

For the data types `TzDate`, `TzDatetime`, `TzTimestamp`, literals are also set in the format meeting ISO 8601, but instead of the optional Z suffix, they specify the IANA name of the time zone, separated by comma (for example, GMT or Europe/Moscow).

For the Decimal parametric data type, two additional arguments are specified:

- Total number of decimal places (up to 35, inclusive).
- Number of places after the decimal point (out of the total number, meaning it can't be larger than the previous argument).

Examples

```
SELECT
  Bool("true"),
  Uint8("0"),
  Int32("-1"),
  Uint32("2"),
  Int64("-3"),
  Uint64("4"),
  Float("-5"),
  Double("6"),
  Decimal("1.23", 5, 2), -- up to 5 decimal places, of which 2 are after the decimal point
  DyNumber("1"),
  String("foo"),
  Utf8("hello"),
  Yson("<a=1>[3;%false]"),
  Json(@@{"a":1,"b":null}@@),
  Date("2017-11-27"),
  Datetime("2017-11-27T13:24:00Z"),
  Timestamp("2017-11-27T13:24:00.123456Z"),
  Interval("P1W2DT2H3M4.567890S"),
  TzDate("2017-11-27,Europe/Moscow"),
  TzDatetime("2017-11-27T13:24:00,America/Los_Angeles"),
  TzTimestamp("2017-11-27T13:24:00.123456,GMT"),
  Uuid("f9d5cc3f-f1dc-4d9c-b97e-766e57ca4ccb");
```

ToBytes and FromBytes

Conversion of primitive data types to a string with their binary representation and back. Numbers are represented in the little endian format.

Examples

```
SELECT
    ToBytes(123), -- "{\u0000\u0000\u0000"
    String::HexEncode(ToBytes(123)) -- "7B000000"
    FromBytes(
        "\xd2\x02\x96\x49\x00\x00\x00\x00",
        Uint64
    ); -- 1234567890ul
```

ByteAt

Getting the byte value inside a string at an index counted from the beginning of the string. If an invalid index is specified, `NULL` is returned.

Arguments:

1. String: `String` or `Utf8`.
2. Index: `Uint32`.

Examples

```
SELECT
    ByteAt("foo", 0), -- 102
    ByteAt("foo", 1), -- 111
    ByteAt("foo", 9); -- NULL
```

...Bit

`TestBit()`, `ClearBit()`, `SetBit()` and `FlipBit()`: Test, clear, set, or flip a bit in an unsigned number using the specified bit sequence number.

Arguments:

1. An unsigned number that's subject to the operation. TestBit is also implemented for strings.
2. Number of the bit.

TestBit returns `true/false`. The other functions return a copy of their first argument with the corresponding conversion.

Examples

```
SELECT
    TestBit(1u, 0), -- true
    SetBit(8u, 0); -- 9
```

Abs

The absolute value of the number.

Examples

```
SELECT Abs(-123); -- 123
```

Just

`Just()`: Change the value's data type to optional from the current data type (i.e., `T` is converted to `T?`).

The reverse operation is Unwrap.

Examples

```
SELECT
  Just("my_string"); --  String?
```

Unwrap

`Unwrap()`: Converting the optional value of the data type to the relevant non-optional type, raising a runtime error if the data is `NULL`. This means that `T?` becomes `T`.

If the value isn't optional, then the function returns its first argument unchanged.

Arguments:

1. Value to be converted.
2. An optional string with a comment for the error text.

Reverse operation is Just.

Examples

```
$value = Just("value");

SELECT Unwrap($value, "Unexpected NULL for $value");
```

Nothing

`Nothing()`: Create an empty value for the specified Optional data type.

Examples

```
SELECT
  Nothing(String?); -- an empty (NULL) value with the String? type
```

Learn more about ParseType and other functions for data types.

Callable

Create a callable value with the specified signature from a lambda function. It's usually used to put callable values into containers.

Arguments:

1. Type.
2. Lambda function.

Examples

```
$lambda = ($x) -> {
    RETURN CAST($x as String)
};

$callables = AsTuple(
    Callable(Callable<(Int32)->String>, $lambda),
    Callable(Callable<(Bool)->String>, $lambda),
);

SELECT $callables.0(10), $callables.1(true);
```

Pickle, Unpickle

`Pickle()` and `StablePickle()` serialize an arbitrary object into a sequence of bytes, if possible. Typical non-serializable objects are Callable and Resource. The serialization format is not versioned and can be used within a single query. For the Dict type, the StablePickle function pre-sorts the keys, and for Pickle, the order of dictionary elements in the serialized representation isn't defined.

`Unpickle()` is the inverse operation (deserialization), where with the first argument being the data type of the result and the second argument is the string with the result of `Pickle()` or `StablePickle()`.

Examples

```
SELECT *
FROM my_table
WHERE Digest::MurMurHash32(
        Pickle(TableRow())
    ) % 10 == 0;

$buf = Pickle(123);
SELECT Unpickle(Int32, $buf);
```

StaticMap

Transforms a structure or tuple by applying a lambda function to each item.

Arguments:

- Structure or tuple.
- Lambda for processing items.

Result: a structure or tuple with the same number and naming of items as in the first argument, and with item data types determined by lambda results.

Examples

```
SELECT *
FROM (
    SELECT
        StaticMap(TableRow(), ($item) -> {
            return CAST($item AS String);
        })
    FROM my_table
) FLATTEN COLUMNS; -- converting all columns to rows
```

StaticZip

Merges structures or tuples element-by-element. All arguments (one or more) must be either structures with the same set of fields or tuples of the same length.
The result will be a structure or tuple, respectively.
Each item of the result is a tuple comprised of items taken from arguments.

Examples

```
$one = <|k1:1, k2:2.0|>;
$two = <|k1:3.0, k2:4|>;

-- Adding two structures item-by-item
SELECT StaticMap(StaticZip($one, $two), ($tuple)->($tuple.0 + $tuple.1)) AS sum;
```

StaticFold, StaticFold1

```
StaticFold(obj:Struct/Tuple, initVal, updateLambda)
StaticFold1(obj:Struct/Tuple, initLambda, updateLambda)
```

Left fold over struct/tuple elements.
The folding of tuples is done in order from the element with the lower index to the element with the larger one; for structures, the order is not guaranteed.

- `obj` - object to fold
- `initVal` - *(for StaticFold)* initial fold state
- `initLambda` - *(for StaticFold1)* lambda that produces initial fold state from the first element
- `updateLambda` - lambda that produces the new state (arguments are the next element and the previous state)

`StaticFold(<|key_1:$el_1, key_2:$el_2, ..., key_n:$el_n|>, $init, $f)` transforms into:

```
$f($el_n, ...$f($el_2, $f($init, el_1))...)
```

`StaticFold1(<|key_1:$el_1, key_2:$el_2, ..., key_n:$el_n|>, $f0, $f)`:

```
$f($el_n, ...$f($el_2, $f($f0($init), el_1))...)
```

`StaticFold1(<||>, $f0, $f)` returns `NULL`.

Works with tuples in the same way.

AggregationFactory

Create a factory for aggregation functions to separately describe the methods of aggregation and data types subject to aggregation.

Arguments:

1. A string in double quotes with the name of an aggregate function, for example "MIN".
2. Optional parameters of the aggregate function that are data-independent. For example, the percentile value in PERCENTILE.

The resulting factory can be used as the second parameter of the function AGGREGATE_BY.
If the aggregate function is applied to two columns instead of one, as, for example, MIN_BY, then in AGGREGATE_BY, the first argument passes a `Tuple` of two values. See more details in the description of the applicable aggregate function.

Examples

```
$factory = AggregationFactory("MIN");
SELECT
    AGGREGATE_BY (value, $factory) AS min_value -- apply the MIN aggregation to the "value" column
FROM my_table;
```

AggregateTransformInput

`AggregateTransformInput()` converts an aggregation factory, for example, obtained using the AggregationFactory function, to other factory, in which the specified transformation of input items is performed before starting aggregation.

Arguments:

1. Aggregation factory.
2. A lambda function with one argument that converts an input item.

Examples

```
$f = AggregationFactory("sum");
$g = AggregateTransformInput($f, ($x) -> (cast($x as Int32)));
$h = AggregateTransformInput($f, ($x) -> ($x * 2));
SELECT ListAggregate([1,2,3], $f); -- 6
SELECT ListAggregate(["1","2","3"], $g); -- 6
SELECT ListAggregate([1,2,3], $h); -- 12
```

AggregateTransformOutput

`AggregateTransformOutput()` converts an aggregation factory, for example, obtained using the AggregationFactory function, to other factory, in which the specified transformation of the result is performed after ending aggregation.

Arguments:

1. Aggregation factory.
2. A lambda function with one argument that converts the result.

Examples

```
$f = AggregationFactory("sum");
$g = AggregateTransformOutput($f, ($x) -> ($x * 2));
SELECT ListAggregate([1,2,3], $f); -- 6
SELECT ListAggregate([1,2,3], $g); -- 12
```

AggregateFlatten

Adapts a factory for aggregation functions, for example, obtained using the AggregationFactory function in a way that allows aggregation of list input items. This operation is similar to FLATTEN LIST BY: Each list item is aggregated.

Arguments:

1. Aggregation factory.

Examples

```
$i = AggregationFactory("AGGREGATE_LIST_DISTINCT");
$j = AggregateFlatten($i);
SELECT AggregateBy(x, $j) from (
   select [1,2] as x
   union all
   select [2,3] as x
); -- [1, 2, 3]
```

Fulltext search

The `FulltextMatch` and `FulltextScore` functions are intended for fulltext search in YDB **via a fulltext index**.

> **Note**
>
> These functions use a fulltext index only when the query is executed with `VIEW IndexName`. See VIEW (Fulltext index) and Fulltext Indexes.

FulltextMatch

`FulltextMatch(text, query)` filters rows by whether the text matches a fulltext query.

```
SELECT id, body
FROM articles VIEW ft_idx
WHERE FulltextMatch(body, "machine learning");
```

Only the first two arguments can be positional. Additional parameters must be passed as **named arguments**.

Supports named arguments:

- `Mode` (String): query mode:
  - `Keywords` (default) — the query is split into individual terms; how they are combined is determined by `DefaultOperator`
  - `Query` — extended syntax with logical operators: required terms via `+`, excluded terms via `-`, exact phrases in double quotes
  - `Wildcard` — wildcard search: `%` matches any substring, `_` matches a single character (similar to `LIKE`); requires an n-gram index
- `DefaultOperator` (String): term combination operator in `Keywords` mode:
  - `And` (default) — all query terms must be present in the text
  - `Or` — terms split into **required** (prefixed with `+`, must appear in every result) and **optional** (no prefix, count toward `MinimumShouldMatch`). Without any `+` prefix, all terms are optional and at least one must match
- `MinimumShouldMatch` (String): minimum number of **optional** terms that must match when `DefaultOperator = "Or"` — specified as an absolute number (for example, `"3"`) or a percentage of the optional terms (for example, `"50%"`). Required (`+`) terms are not counted

`Mode` and `DefaultOperator` values are case-insensitive.

`Wildcard` example

If the index is created with n-gram filtering, you can use `%` and `_` patterns similar to `LIKE`.

```
SELECT id, title
FROM articles VIEW ft_idx
WHERE FulltextMatch(body, "mach% learn%", "Wildcard" AS Mode)
LIMIT 20;
```

MinimumShouldMatch example

An 8-term query where at least half of the terms must match:

```
SELECT id
FROM articles VIEW ft_idx
WHERE FulltextMatch(
  body,
  "machine learning neural networks deep learning large scale data recommendations search",
  "Keywords" AS Mode,
  "Or" AS DefaultOperator,
  "50%" AS MinimumShouldMatch
);
```

In this example, `Mode` is set to `Keywords` (treating the query as a set of terms), `DefaultOperator` is set to `Or` (allowing matching any subset of terms), and `MinimumShouldMatch` is set to `"50%"` (requiring at least 4 out of 8 terms to match). This helps filter out documents that contain only one or two words from a long query.

Required term (`+`) example

Prefix a term with `+` in `Keywords` mode with `DefaultOperator = "Or"` to require it in every result. This follows Lucene's required term syntax.

```
SELECT id
FROM articles VIEW ft_idx
WHERE FulltextMatch(
  body,
  "+machine learning neural networks",
  "Or" AS DefaultOperator,
  "1" AS MinimumShouldMatch
);
```

This returns documents that contain "machine" (required) and at least 1 of "learning", "neural", "networks" (optional). `MinimumShouldMatch` counts only the optional terms. If all terms are prefixed with `+`, the query is a strict AND.

FulltextScore

`FulltextScore(text, query)` returns a relevance score based on the BM25 algorithm and can be used for ranking results.

Requires the `fulltext_relevance` index type.

```
SELECT id, FulltextScore(body, "machine learning") AS relevance
FROM articles VIEW ft_idx
WHERE FulltextScore(body, "machine learning") > 0
ORDER BY relevance DESC
LIMIT 10;
```

Only the first two arguments can be positional. Additional parameters must be passed as **named arguments**.

Supports named arguments:

- `DefaultOperator` (String): term combination operator — `And` (default, all terms must be present) or `Or` (terms split into **required** with `+` prefix and **optional** without; at least `MinimumShouldMatch` optional terms must match, and every required term must be present)
- `MinimumShouldMatch` (String): when `DefaultOperator = "Or"`, minimum number of **optional** terms that must match — specified as an absolute number (for example, `"2"`) or a percentage of the optional terms (for example, `"50%"`). Required (`+`) terms are not counted
- `K1` (Double): term frequency saturation parameter in BM25 — controls how strongly repeated occurrences of a term affect the score; typical range: 1.2–2.0
- `B` (Double): document length normalization parameter in BM25 — `0.0` disables normalization, `1.0` fully normalizes by document length; typical value: 0.75

Example:

```
SELECT id,
       FulltextScore(body, "machine learning", "Or" AS DefaultOperator, "1" AS MinimumShouldMatch, 0.75 AS K
1, 1.2 AS B) AS relevance
FROM articles VIEW ft_idx
WHERE FulltextScore(body, "machine learning", "Or" AS DefaultOperator, "1" AS MinimumShouldMatch, 0.75 AS K1,
1.2 AS B) > 0
ORDER BY relevance DESC;
```

> **Note**
>
> `MinimumShouldMatch` is supported only when `DefaultOperator` is set to `Or`. When `DefaultOperator` is set to `And`, use `FulltextScore` without `MinimumShouldMatch`.

Aggregate functions

COUNT

Counting the number of rows in the table (if `*` or constant is specified as the argument) or non-empty values in a table column (if the column name is specified as an argument).

Like other aggregate functions, it can be combined with GROUP BY to get statistics on the parts of the table that correspond to the values in the columns being grouped. Use the modifier DISTINCT to count distinct values.

Examples

```
SELECT COUNT(*) FROM my_table;
```

```
SELECT key, COUNT(value) FROM my_table GROUP BY key;
```

```
SELECT COUNT(DISTINCT value) FROM my_table;
```

MIN and MAX

Minimum or maximum value.

As an argument, you may use an arbitrary computable expression with a numeric result.

Examples

```
SELECT MIN(value), MAX(value) FROM my_table;
```

SUM

Sum of the numbers.

As an argument, you may use an arbitrary computable expression with a numeric result.

Integers are automatically expanded to 64 bits to reduce the risk of overflow.

```
SELECT SUM(value) FROM my_table;
```

AVG

Arithmetic average.

As an argument, you may use an arbitrary computable expression with a numeric result.

Integer values and time intervals are automatically converted to Double.

Examples

```
SELECT AVG(value) FROM my_table;
```

COUNT_IF

Number of rows for which the expression specified as the argument is true (the expression's calculation result is true).

The value `NULL` is equated to `false` (if the argument type is `Bool?`).

The function *does not* do the implicit type casting to Boolean for strings and numbers.

Examples

```
SELECT
  COUNT_IF(value % 2 == 1) AS odd_count
FROM my_table;
```

Note

To count distinct values in rows meeting the condition, unlike other aggregate functions, you can't use the modifier DISTINCT because arguments contain no values. To get such a result, use a query like this:

```
SELECT
    COUNT(DISTINCT IF(value % 2 == 1, value))
FROM my_table;
```

SUM_IF and AVG_IF

Sum or arithmetic average, but only for the rows that satisfy the condition passed by the second argument.

Therefore, `SUM_IF(value, condition)` is a slightly shorter notation for `SUM(IF(condition, value))`, same for `AVG`. The argument's data type expansion is similar to the same-name functions without a suffix.

Examples

```
SELECT
    SUM_IF(value, value % 2 == 1) AS odd_sum,
    AVG_IF(value, value % 2 == 1) AS odd_avg,
FROM my_table;
```

When you use aggregation factories, a `Tuple` containing a value and a predicate is passed as the first AGGREGATE_BY argument.

```
$sum_if_factory = AggregationFactory("SUM_IF");
$avg_if_factory = AggregationFactory("AVG_IF");

SELECT
    AGGREGATE_BY(AsTuple(value, value % 2 == 1), $sum_if_factory) AS odd_sum,
    AGGREGATE_BY(AsTuple(value, value % 2 == 1), $avg_if_factory) AS odd_avg
FROM my_table;
```

SOME

Get the value for an expression specified as an argument, for one of the table rows. Gives no guarantee of which row is used. It's similar to the any() function in ClickHouse.

Because of no guarantee, `SOME` is computationally cheaper than MIN / MAX often used in similar situations.

Examples

```
SELECT
  SOME(value)
FROM my_table;
```

Alert

When the aggregate function `SOME` is called multiple times, it's **not** guaranteed that all the resulting values are taken from the same row of the source table. To get this guarantee, pack the values into any container and pass it to `SOME`. For example, in the case of a structure, you can apply AsStruct

CountDistinctEstimate, HyperLogLog, and HLL

Approximating the number of unique values using the HyperLogLog algorithm. Logically, it does the same thing as COUNT(DISTINCT ...), but runs much faster at the cost of some error.

Arguments:

1. Estimated value
2. Accuracy (4 to 18 inclusive, 14 by default).

By selecting accuracy, you can trade added resource and RAM consumption for decreased error.

All the three functions are aliases at the moment, but `CountDistinctEstimate` may start using a different algorithm in the future.

Examples

```
SELECT
  CountDistinctEstimate(my_column)
FROM my_table;
```

```
SELECT
  HyperLogLog(my_column, 4)
FROM my_table;
```

AGGREGATE_LIST

Get all column values as a list. When combined with `DISTINCT,` it returns only distinct values. The optional second parameter sets the maximum number of values to be returned. A zero limit value means unlimited.

If you know already that you have few distinct values, use the `AGGREGATE_LIST_DISTINCT` aggregate function to build the same result in memory (that might not be enough for a large number of distinct values).

The order of elements in the result list depends on the implementation and can't be set externally. To return an ordered list, sort the result, for example, with ListSort.

To return a list of multiple values from one line, **DO NOT** use the `AGGREGATE_LIST` function several times, but add all the needed values to a container, for example, via AsList or AsTuple, then pass this container to a single `AGGREGATE_LIST` call.

For example, you can combine it with `DISTINCT` and the function String::JoinFromList (it's an equivalent of `','.join(list)` in Python) to output to a string all the values found in the column after GROUP BY.

Examples

```
SELECT
   AGGREGATE_LIST( region ),
   AGGREGATE_LIST( region, 5 ),
   AGGREGATE_LIST( DISTINCT region ),
   AGGREGATE_LIST_DISTINCT( region ),
   AGGREGATE_LIST_DISTINCT( region, 5 )
FROM users
```

```
-- An equivalent of GROUP_CONCAT in MySQL
SELECT
    String::JoinFromList(CAST(AGGREGATE_LIST(region, 2) AS List<String>), ",")
FROM users
```

These functions also have a short notation: `AGG_LIST` and `AGG_LIST_DISTINCT`.

Alert

Execution is **NOT** lazy, so when you use it, be sure that the list has a reasonable size (about a thousand items or less). To stay on the safe side, better use a second optional numeric argument that limits the number of items in the list.

MAX_BY and MIN_BY

Return the value of the first argument for the table row where the second argument is minimum/maximum.

You can optionally specify the third argument N that affects behavior if the table has multiple rows with the same minimum or maximum value:

- If N is omitted, the value of one of the rows is returned, and the other rows are discarded.
- If N is specified, the list is returned with all values, but their number can't exceed N. All values after the number are discarded.

When choosing N, we recommend that you don't exceed several hundreds or thousands to avoid issues with the limited memory available on YDB clusters.

If your task needs absolutely all values, and their number is measured in dozens of thousands or more, then instead of those aggregate functions better use `JOIN` on the source table with a subquery doing `GROUP BY + MIN/MAX` on the desired columns of this table.

Attention

If the second argument is always `NULL`, the aggregation result is `NULL`.

When you use aggregation factories, a `Tuple` containing a value and a key is passed as the first AGGREGATE_BY argument.

Examples

```
SELECT
  MIN_BY(value, LENGTH(value)),
  MAX_BY(value, key, 100)
FROM my_table;
```

```
$min_by_factory = AggregationFactory("MIN_BY");
$max_by_factory = AggregationFactory("MAX_BY", 100);

SELECT
    AGGREGATE_BY(AsTuple(value, LENGTH(value)), $min_by_factory),
    AGGREGATE_BY(AsTuple(value, key), $max_by_factory)
FROM my_table;
```

TOP and BOTTOM

Return a list of the maximum/minimum values of an expression. The first argument is an expression, the second argument limits the number of items.

Examples

```
SELECT
    TOP(key, 3),
    BOTTOM(value, 3)
FROM my_table;
```

```
$top_factory = AggregationFactory("TOP", 3);
$bottom_factory = AggregationFactory("BOTTOM", 3);

SELECT
    AGGREGATE_BY(key, $top_factory),
    AGGREGATE_BY(value, $bottom_factory)
FROM my_table;
```

TOP_BY and BOTTOM_BY

Return a list of values of the first argument for the rows containing the maximum/minimum values of the second argument. The third argument limits the number of items in the list.

When you use aggregation factories, a `Tuple` containing a value and a key is passed as the first AGGREGATE_BY argument. In this case, the limit for the number of items is passed by the second argument at factory creation.

Examples

```
SELECT
    TOP_BY(value, LENGTH(value), 3),
    BOTTOM_BY(value, key, 3)
FROM my_table;
```

```
$top_by_factory = AggregationFactory("TOP_BY", 3);
$bottom_by_factory = AggregationFactory("BOTTOM_BY", 3);

SELECT
    AGGREGATE_BY(AsTuple(value, LENGTH(value)), $top_by_factory),
    AGGREGATE_BY(AsTuple(value, key), $bottom_by_factory)
FROM my_table;
```

TOPFREQ and MODE

Getting an **approximate** list of the most common values in a column with an estimation of their count. Returns a list of structures with two fields:

- `Value`: the frequently occurring value that was found.
- `Frequency`: An estimated value occurrence in the table.

Required argument: the value itself.

Optional arguments:

1. For `TOPFREQ`, the desired number of items in the result. `MODE` is an alias to `TOPFREQ` with this argument set to 1. For `TOPFREQ`, this argument is also 1 by default.
2. The number of items in the buffer used: lets you trade memory consumption for accuracy. Default: 100.

Examples

```
SELECT
    MODE(my_column),
    TOPFREQ(my_column, 5, 1000)
FROM my_table;
```

STDDEV and VARIANCE

Standard deviation and variance in a column. Those functions use a single-pass parallel algorithm, whose result may differ from the more common methods requiring two passes through the data.

By default, the sample variance and standard deviation are calculated. Several write methods are available:

- with the `POPULATION` suffix/prefix, for example: `VARIANCE_POPULATION`, `POPULATION_VARIANCE` calculates the variance or standard deviation for the population.
- With the `SAMPLE` suffix/prefix or without a suffix, for example, `VARIANCE_SAMPLE`, `SAMPLE_VARIANCE`, `SAMPLE` calculate sample variance and standard deviation.

Several abbreviated aliases are also defined, for example, `VARPOP` or `STDDEVSAMP`.

If all the values passed are `NULL`, it returns `NULL`.

Examples

```
SELECT
  STDDEV(numeric_column),
  VARIANCE(numeric_column)
FROM my_table;
```

CORRELATION and COVARIANCE

Correlation and covariance between two columns.

Abbreviated versions are also available: `CORR` or `COVAR`. For covariance, there are also versions with the `SAMPLE` / `POPULATION` suffix that are similar to VARIANCE above.

Unlike most other aggregate functions, they don't skip `NULL`, but accept it as 0.

When you use aggregation factories, a `Tuple` containing two values is passed as the first AGGREGATE_BY argument.

Examples

```
SELECT
  CORRELATION(numeric_column, another_numeric_column),
  COVARIANCE(numeric_column, another_numeric_column)
FROM my_table;
```

```
$corr_factory = AggregationFactory("CORRELATION");

SELECT
    AGGREGATE_BY(AsTuple(numeric_column, another_numeric_column), $corr_factory)
FROM my_table;
```

PERCENTILE and MEDIAN

Calculating percentiles using the amortized version of the TDigest algorithm. `MEDIAN`: An alias for `PERCENTILE(N, 0.5)`.

> **Restriction**
>
> The first argument (N) must be a table column name. If you need to bypass this restriction, use a subquery. The restriction is introduced to simplify calculations, since the implementation merges the calls with the same first argument (N) into a single pass.

```
SELECT
    MEDIAN(numeric_column),
    PERCENTILE(numeric_column, 0.99)
FROM my_table;
```

HISTOGRAM

Plotting an approximate histogram based on a numeric expression with automatic selection of buckets.

Auxiliary functions

Basic settings

You can limit the number of buckets using an optional argument. The default value is 100. Keep in mind that added accuracy costs you more computing resources and may negatively affect the query execution time. In extreme cases, it may affect your query success.

Support for weights

You can specify a "weight" for each value used in the histogram. To do this, pass to the aggregate function the second argument with an expression for calculating the weight. The weight of `1.0` is always used by default. If you use non-standard weights, you may also use the third argument to limit the number of buckets.

If you pass two arguments, the meaning of the second argument is determined by its type (if it's an integer literal, it limits the number of buckets, otherwise it's used as a weight).

If you need an accurate histogram

1. You can use the aggregate functions described below with fixed bucket grids: LinearHistogram or LogarithmicHistogram.
2. You can calculate the bucket number for each row and apply to it GROUP BY.

When you use aggregation factories, a `Tuple` containing a value and a weight is passed as the first AGGREGATE_BY argument.

Examples

```
SELECT
    HISTOGRAM(numeric_column)
FROM my_table;
```

```
SELECT
    Histogram::Print(
        HISTOGRAM(numeric_column, 10),
        50
    )
FROM my_table;
```

```
$hist_factory = AggregationFactory("HISTOGRAM");

SELECT
    AGGREGATE_BY(AsTuple(numeric_column, 1.0), $hist_factory)
FROM my_table;
```

LinearHistogram, LogarithmicHistogram, and LogHistogram

Plotting a histogram based on an explicitly specified fixed bucket scale.

Arguments:

1. Expression used to plot the histogram. All the following arguments are optional.
2. Spacing between the `LinearHistogram` buckets or the logarithm base for `LogarithmicHistogram` / `LogHistogram` (those are aliases). In both cases, the default value is 10.
3. Minimum value. By default, it's minus infinity.
4. Maximum value. By default, it's plus infinity.

The format of the result is totally similar to adaptive histograms, so you can use the same set of auxiliary functions.

If the spread of input values is uncontrollably large, we recommend that you specify the minimum and maximum values to prevent potential failures due to high memory consumption.

Examples

```
SELECT
    LogarithmicHistogram(numeric_column, 2)
FROM my_table;
```

BOOL_AND, BOOL_OR and BOOL_XOR

Signature

```
BOOL_AND(Bool?)->Bool?
BOOL_OR(Bool?)->Bool?
BOOL_XOR(Bool?)->Bool?
```

Apply the relevant logical operation (`AND` / `OR` / `XOR`) to all values in a Boolean column or expression.

Unlike most other aggregate functions, these functions **don't skip** `NULL` during aggregation and use the following rules:

- `true AND null == null`
- `false OR null == null`

For `BOOL_AND` :

- If at least one `NULL` value is present, the result is `NULL` regardless of `true` values in the expression.
- If at least one `false` value is present, the result changes to `false` regardless of `NULL` values in the expression.

For `BOOL_OR` :

- If at least one `NULL` value is present, the result changes to `NULL` regardless of `false` values in the expression.
- If at least one `true` value is present, the result changes to `true` regardless of `NULL` values in the expression.

For `BOOL_XOR` :

- The result is `NULL` if any `NULL` is found.

Examples of such behavior can be found below.

To skip `NULL` values during aggregation, use the `MIN` / `MAX` or `BIT_AND` / `BIT_OR` / `BIT_XOR` functions.

Examples

```
$data = [
    <|nonNull: true, nonFalse: true, nonTrue: NULL, anyVal: true|>,
    <|nonNull: false, nonFalse: NULL, nonTrue: NULL, anyVal: NULL|>,
    <|nonNull: false, nonFalse: NULL, nonTrue: false, anyVal: false|>,
];

SELECT
    BOOL_AND(nonNull) as nonNullAnd,      -- false
    BOOL_AND(nonFalse) as nonFalseAnd,    -- NULL
    BOOL_AND(nonTrue) as nonTrueAnd,      -- false
    BOOL_AND(anyVal) as anyAnd,           -- false
    BOOL_OR(nonNull) as nonNullOr,        -- true
    BOOL_OR(nonFalse) as nonFalseOr,      -- true
    BOOL_OR(nonTrue) as nonTrueOr,        -- NULL
    BOOL_OR(anyVal) as anyOr,             -- true
    BOOL_XOR(nonNull) as nonNullXor,      -- true
    BOOL_XOR(nonFalse) as nonFalseXor,    -- NULL
    BOOL_XOR(nonTrue) as nonTrueXor,      -- NULL
    BOOL_XOR(anyVal) as anyXor,           -- NULL
FROM AS_TABLE($data);
```

BIT_AND, BIT_OR and BIT_XOR

Apply the relevant bitwise operation to all values of a numeric column or expression.

Examples

```
SELECT
    BIT_XOR(unsigned_numeric_value)
FROM my_table;
```

SessionStart

No arguments. It's allowed only if there is SessionWindow in GROUP BY / PARTITION BY.
Returns the value of the `SessionWindow` key column. If `SessionWindow` has two arguments, it returns the minimum value of the first argument within the group/section.
In the case of the expanded version `SessionWindow`, it returns the value of the second element from the tuple returned by `<calculate_lambda>`, for which the first tuple element is `True`.

AGGREGATE_BY and MULTI_AGGREGATE_BY

Applying an aggregation factory to all values of a column or expression. The `MULTI_AGGREGATE_BY` function requires that the value of a column or expression has a structure, tuple, or list, and applies the factory to each individual element, placing the result in a container of the same format. If different values of a column or expression contain lists of different length, the resulting list will have the smallest of the source lengths.

1. Column, `DISTINCT` column or expression.
2. Factory.

Examples

```
$count_factory = AggregationFactory("COUNT");

SELECT
    AGGREGATE_BY(DISTINCT column, $count_factory) as uniq_count
FROM my_table;

SELECT
    MULTI_AGGREGATE_BY(nums, AggregationFactory("count")) as count,
    MULTI_AGGREGATE_BY(nums, AggregationFactory("min")) as min,
    MULTI_AGGREGATE_BY(nums, AggregationFactory("max")) as max,
    MULTI_AGGREGATE_BY(nums, AggregationFactory("avg")) as avg,
    MULTI_AGGREGATE_BY(nums, AggregationFactory("percentile", 0.9)) as p90
FROM my_table;
```

List of window functions in YQL

The syntax for calling window functions is detailed in a separate article.

Aggregate functions

All aggregate functions can also be used as window functions.
In this case, each row includes an aggregation result obtained on a set of rows from the window frame.

Examples

```
SELECT
    SUM(int_column) OVER w1 AS running_total,
    SUM(int_column) OVER w2 AS total,
FROM my_table
WINDOW
    w1 AS (ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW),
    w2 AS ();
```

ROW_NUMBER

Row number within a partition. No arguments.

Signature

```
ROW_NUMBER()->Uint64
```

Examples

```
SELECT
    ROW_NUMBER() OVER w AS row_num
FROM my_table
WINDOW w AS (ORDER BY key);
```

LAG / LEAD

Accessing a value from a row in the section that lags behind (`LAG`) or leads (`LEAD`) the current row by a fixed number. The first argument specifies the expression to be accessed, and the second argument specifies the offset in rows. You may omit the offset. By default, the neighbor row is used: the previous or next, respectively (hence, 1 is assumed by default). For the rows having no neighbors at a given distance (for example, `LAG(expr, 3)` `NULL` is returned in the first and second rows of the section).

Signature

```
LEAD(T[,Int32])->T?
LAG(T[,Int32])->T?
```

Examples

```
SELECT
   int_value - LAG(int_value) OVER w AS int_value_diff
FROM my_table
WINDOW w AS (ORDER BY key);
```

```
SELECT item, odd, LAG(item, 1) OVER w as lag1 FROM (
    SELECT item, item % 2 as odd FROM (
        SELECT AsList(1, 2, 3, 4, 5, 6, 7) as item
    )
    FLATTEN BY item
)
WINDOW w As (
    PARTITION BY odd
    ORDER BY item
);

/* Output:
item  odd  lag1
--------------------
2  0  NULL
4  0  2
6  0  4
1  1  NULL
3  1  1
5  1  3
7  1  5
*/
```

FIRST_VALUE / LAST_VALUE

Access values from the first and last rows (using the `ORDER BY` clause for the window) of the window frame. The only argument is the expression that you need to access.

Optionally, `OVER` can be preceded by the additional modifier `IGNORE NULLS`. It changes the behavior of functions to the first or last **non-empty** (i.e., non-`NULL`) value among the window frame rows. The antonym of this modifier is `RESPECT NULLS`: it's the default behavior that can be omitted.

Signature

```
FIRST_VALUE(T)->T?
LAST_VALUE(T)->T?
```

Examples

```
SELECT
   FIRST_VALUE(my_column) OVER w
FROM my_table
WINDOW w AS (ORDER BY key);
```

```
SELECT
   LAST_VALUE(my_column) IGNORE NULLS OVER w
FROM my_table
WINDOW w AS (ORDER BY key);
```

NTH_VALUE

Access a value from a row specified by position in the window's `ORDER BY` order within window frame. Arguments - the expression to access and the row number, starting with 1.

Optionally, the `IGNORE NULLS` modifier can be specified before `OVER`, which causes rows with `NULL` in the first argument's value to be skipped. The antonym of this modifier is `RESPECT NULLS`, which is the default behavior and may be skipped.

Signature

```
NTH_VALUE(T,N)->T?
```

Examples

```
SELECT
   NTH_VALUE(my_column, 2) OVER w
FROM my_table
WINDOW w AS (ORDER BY key);
```

```
SELECT
   NTH_VALUE(my_column, 3) IGNORE NULLS OVER w
FROM my_table
WINDOW w AS (ORDER BY key);
```

RANK / DENSE_RANK / PERCENT_RANK

Number the groups of neighboring rows in the partition with the same expression value in the argument. `DENSE_RANK` numbers the groups one by one, and `RANK` skips `(N - 1)` values, with `N` being the number of rows in the previous group. `PERCENT_RANK` returns the relative rank of the current row: .

If there is no argument, it uses the order specified in the `ORDER BY` section in the window definition.
If the argument is omitted and `ORDER BY` is not specified, then all rows are considered equal to each other.

Note

Passing an argument to `RANK` / `DENSE_RANK` / `PERCENT_RANK` is a non-standard extension in YQL.

Signature

```
RANK([T])->Uint64
DENSE_RANK([T])->Uint64
PERCENT_RANK([T])->Double
```

Examples

```
SELECT
   RANK(my_column) OVER w
FROM my_table
WINDOW w AS (ORDER BY key);
```

```
SELECT
   DENSE_RANK() OVER w
FROM my_table
WINDOW w AS (ORDER BY my_column);
```

```
SELECT
   PERCENT_RANK() OVER w
FROM my_table
WINDOW w AS (ORDER BY my_column);
```

NTILE

Distributes the rows of an ordered partition into a specified number of groups. The groups are numbered starting with one. For each row, the `NTILE` function returns the number of the group to which the row belongs.

Signature

```
NTILE(Uint64)->Uint64
```

Examples

```
SELECT
    NTILE(10) OVER w AS group_num
FROM my_table
WINDOW w AS (ORDER BY key);
```

CUME_DIST

Returns the relative position (> 0 and <= 1) of a row within a partition. No arguments.

Signature

```
CUME_DIST()->Double
```

Examples

```
SELECT
    CUME_DIST() OVER w AS dist
FROM my_table
WINDOW w AS (ORDER BY key);
```

SessionState()

A non-standard window function `SessionState()` (without arguments) lets you get the session calculation status from SessionWindow for the current row.
It's allowed only if `SessionWindow()` is present in the `PARTITION BY` section in the window definition.

Functions for lists

ListCreate

Construct an empty list. The only argument specifies a string describing the data type of the list cell, or the type itself obtained using relevant functions. YQL doesn't support lists with an unknown cell type.

Documentation for the type definition format.

Examples

```
SELECT ListCreate(Tuple<String,Double?>);
```

```
SELECT ListCreate(OptionalType(DataType("String")));
```

AsList and AsListStrict

Construct a list based on one or more arguments. The argument types must be compatible in the case of `AsList` and strictly match in the case of `AsListStrict`.

Examples

```
SELECT AsList(1, 2, 3, 4, 5);
```

ListLength

The count of items in the list.

Examples

ListHasItems

Check that the list contains at least one item.

Examples

ListCollect

Convert a lazy list (it can be built by such functions as ListFilter, ListMap, ListFlatMap) to an eager list. In contrast to a lazy list, where each new pass re-calculates the list contents, in an eager list the content is built at once by consuming more memory.

Examples

ListSort, ListSortAsc, and ListSortDesc

Sort the list. By default, the ascending sorting order is applied (`ListSort` is an alias for `ListSortAsc`).

Arguments:

1. List.
2. An optional expression to get the sort key from a list element (it's the element itself by default).

Examples

```
$list = AsList(
    AsTuple("x", 3),
    AsTuple("xx", 1),
    AsTuple("a", 2)
);

SELECT ListSort($list, ($x) -> {
    RETURN $x.1;
});
```

Note

The example used a lambda function.

ListExtend and ListExtendStrict

Sequentially join lists (concatenation of lists). The arguments can be lists, optional lists, and `NULL`.
The types of list items must be compatible in the case of `ListExtend` and strictly match in the case of `ListExtendStrict`.
If at least one of the lists is optional, then the result is also optional.
If at least one argument is `NULL`, then the result type is `NULL`.

ListUnionAll

Sequentially join lists of structures (concatenation of lists). A field is added to the output list of structures if it exists in at least one source list, but if there is no such field in any list, it is added as NULL. In the case when a field is present in two or more lists, the output field is cast to the common type.

If at least one of the lists is optional, then the result is also optional.

ListZip and ListZipAll

Based on the input lists, build a list of pairs containing the list items with matching indexes (`List<Tuplefirst_list_element_type,second_list_element_type>`).

The length of the returned list is determined by the shortest list for ListZip and the longest list for ListZipAll.
When the shorter list is exhausted, a `NULL` value of a relevant optional type is paired with the elements of the longer list.

ListEnumerate

Build a list of pairs (Tuple) containing the element number and the element itself (`List<TupleUint64,list_element_type>`).

ListReverse

Reverse the list.

ListSkip

Returns a copy of the list, skipping the specified number of its first elements.

The first argument specifies the source list and the second argument specifies how many elements to skip.

ListTake

Returns a copy of the list containing a limited number of elements from the second list.

The first argument specifies the source list and the second argument specifies the maximum number of elements to be taken from the beginning of the list.

ListSample and ListSampleN

Returns a sample without replacement from the list.

- `ListSample` chooses elements independently with the specified probability.
- `ListSampleN` chooses a sample of the specified size (if the length of the list is less than the sample size, returns the original list).

If the probability/sample size is NULL, returns the original list.

An optional argument is used to control randomness, see documentation for `Random`.

Examples

```
ListSample(List<T>, Double?[, U])->List<T>
ListSample(List<T>?, Double?[, U])->List<T>?

ListSampleN(List<T>, Uint64?[, U])->List<T>
ListSampleN(List<T>?, Uint64?[, U])->List<T>?
```

```
$list = AsList(1, 2, 3, 4, 5);

SELECT ListSample($list, 0.5);  -- [1, 2, 5]
SELECT ListSampleN($list, 2);  -- [4, 2]
```

ListShuffle

Returns a shuffled copy of the list. An optional argument is used to control randomness, see documentation for `Random`.

Examples

```
ListShuffle(List<T>[, U])->List<T>
ListShuffle(List<T>?[, U])->List<T>?
```

```
$list = AsList(1, 2, 3, 4, 5);

SELECT ListShuffle($list);  -- [1, 3, 5, 2, 4]
```

ListIndexOf

Searches the list for an element with the specified value and returns its index at the first occurrence. Indexes count from 0. If such element is missing, it returns `NULL`.

ListMap, ListFilter, and ListFlatMap

Apply the function specified as the second argument to each list element. The functions differ in their returned result:

- `ListMap` returns a list with results.
- `ListFlatMap` returns a list with results, combining and expanding the first level of results (lists or optional values) for each item.
- `ListFilter` leaves only those elements where the function returned `true`.

> **Note**
>
> In `ListFlatMap`, using optional values in function results is deprecated, use the combination of `ListNotNull` and `ListMap` instead.

Arguments:

1. Source list.
2. Functions for processing list elements, such as:
   - Lambda function.
   - `Module::Function` - C++ UDF.

ListNotNull

Applies transformation to the source list, skipping empty optional items and strengthening the item type to non-optional. For a list with non-optional items, it returns the unchanged source list.

If the source list is optional, then the output list is also optional.

Examples

```
SELECT ListNotNull([1,2]),   -- [1,2]
    ListNotNull([3,null,4]); -- [3,4]
```

ListFlatten

Expands the list of lists into a flat list, preserving the order of items. As the top-level list item you can use an optional list that is interpreted as an empty list in the case of `NULL`.

If the source list is optional, then the output list is also optional.

Examples

```
SELECT ListFlatten([[1,2],[3,4]]),   -- [1,2,3,4]
    ListFlatten([null,[3,4],[5,6]]); -- [3,4,5,6]
```

ListUniq

Returns a copy of the list containing only distinct elements.

ListAny and ListAll

Returns `true` for a list of Boolean values, if:

- `ListAny`: At least one element is `true`.
- `ListAll`: All elements are `true`.

Otherwise, it returns false.

ListHas

Show whether the list contains the specified element. In this case, `NULL` values are considered equal to each other, and with a `NULL` input list, the result is always `false`.

ListHead, ListLast

Returns the first and last item of the list.

ListMin, ListMax, ListSum and ListAvg

Apply the appropriate aggregate function to all elements of the numeric list.

ListFold, ListFold1

Folding a list.

Arguments:

1. List
2. Initial state `U` for `ListFold`, `initLambda(item:T)->U` for `ListFold1`
3. `updateLambda(item:T, state:U)->U`

Type returned:
`U` for `ListFold`, `U?` for `ListFold1`.

```
$l = [1, 4, 7, 2];
$y = ($x, $y) -> { RETURN $x + $y; };
$z = ($x) -> { RETURN 4 * $x; };

SELECT
    ListFold($l, 6, $y) AS fold,                    -- 20
    ListFold([], 3, $y) AS fold_empty,              -- 3
    ListFold1($l, $z, $y) AS fold1,                 -- 17
    ListFold1([], $z, $y) AS fold1_empty;           -- Null
```

ListFoldMap, ListFold1Map

Converts each list item i by calling the handler(i, state).

Arguments:

1. List
2. Initial state `S` for `ListFoldMap`, `initLambda(item:T)->tuple (U S)` for `ListFold1Map`
3. `handler(item:T, state:S)->tuple (U S)`

Type returned: `List` of `U` items.

Examples

```
$l = [1, 4, 7, 2];
$x = ($i, $s) -> { RETURN ($i * $s, $i + $s); };
$t = ($i) -> { RETURN ($i + 1, $i + 2); };

SELECT
    ListFoldMap([], 1, $x),               -- []
    ListFoldMap($l, 1, $x),               -- [1, 8, 42, 26]
    ListFold1Map([], $t, $x),             -- []
    ListFold1Map($l, $t, $x);             -- [2, 12, 49, 28]
```

ListFromRange

Generate a sequence of numbers with the specified step. It's similar to `xrange` in Python 2, but additionally supports floats.

Arguments:

1. Start
2. End
3. Step (optional, 1 by default)

Specifics:

- The end is not included, i.e. `ListFromRange(1,3) == AsList(1,2)`.
- The type for the resulting elements is selected as the broadest from the argument types. For example, `ListFromRange(1, 2, 0.5)` results in a `Double` list.
- If the start and the end is one of the date representing type, the step has to be `Interval`.
- The list is "lazy", but if it's used incorrectly, it can still consume a lot of RAM.
- If the step is positive and the end is less than or equal to the start, the result list is empty.
- If the step is negative and the end is greater than or equal to the start, the result list is empty.
- If the step is neither positive nor negative (0 or NaN), the result list is empty.
- If any of the parameters is optional, the result list is optional.
- If any of the parameters is `NULL`, the result is `NULL`.

Examples

```
SELECT
    ListFromRange(-2, 2), -- [-2, -1, 0, 1]
    ListFromRange(2, 1, -0.5); -- [2.0, 1.5]
```

Signature

```
ListFromRange(T{Flags:AutoMap}, T{Flags:AutoMap}, T?)->LazyList<T> -- T — numeric type
ListFromRange(T{Flags:AutoMap}, T{Flags:AutoMap}, I?)->LazyList<T> -- T — type, representing date/time, I — i
nterval
```

ListReplicate

Creates a list containing multiple copies of the specified value.

Required arguments:

1. Value.
2. Number of copies.

Examples

```
SELECT ListReplicate(true, 3); -- [true, true, true]
```

ListConcat

Concatenates a list of strings into a single string.
You can set a separator as the second parameter.

ListExtract

For a list of structures, it returns a list of contained fields having the specified name.

ListTakeWhile, ListSkipWhile

`ListTakeWhile` returns a list from the beginning while the predicate is true, then the list ends.

`ListSkipWhile` skips the list segment from the beginning while the predicate is true, then returns the rest of the list ignoring the predicate.
`ListTakeWhileInclusive` returns a list from the beginning while the predicate is true. Then the list ends, but it also includes the item on which the stopping predicate triggered.
`ListSkipWhileInclusive` skips a list segment from the beginning while the predicate is true, then returns the rest of the list disregarding the predicate, but excluding the element that matched the predicate and starting with the next element after it.

Required arguments:

1. List.
2. Predicate.

If the input list is optional, then the result is also optional.

Examples

```
$data = AsList(1, 2, 5, 1, 2, 7);

SELECT
    ListTakeWhile($data, ($x) -> {return $x <= 3}), -- [1, 2]
    ListSkipWhile($data, ($x) -> {return $x <= 3}), -- [5, 1, 2, 7]
    ListTakeWhileInclusive($data, ($x) -> {return $x <= 3}), -- [1, 2, 5]
    ListSkipWhileInclusive($data, ($x) -> {return $x <= 3}); -- [1, 2, 7]
```

ListAggregate

Apply the aggregation factory to the passed list.
If the passed list is empty, the aggregation result is the same as for an empty table: 0 for the `COUNT` function and `NULL` for other functions.
If the passed list is optional and `NULL`, the result is also `NULL`.

Arguments:

1. List.
2. Aggregation factory.

Examples

```
SELECT ListAggregate(AsList(1, 2, 3), AggregationFactory("Sum")); -- 6
```

ToDict and ToMultiDict

Convert a list of tuples containing key-value pairs to a dictionary. In case of conflicting keys in the input list, `ToDict` leaves the first value and `ToMultiDict` builds a list of all the values.

It means that:

- `ToDict` converts `List<TupleK, V="">` to `Dict<K, V="">`
- `ToMultiDict` converts `List<TupleK, V>` to `Dict<K, List<V>>`

Optional lists are also supported, resulting in an optional dictionary.

ToSet

Converts a list to a dictionary where the keys are unique elements of this list, and values are omitted and have the type `Void`. For the `List<T>` list, the result type is `Dict<T, Void="">`.
An optional list is also supported, resulting in an optional dictionary.

Inverse function: get a list of keys for the DictKeys dictionary.

ListTop, ListTopAsc, ListTopDesc, ListTopSort, ListTopSortAsc и ListTopSortDesc

Select top values from the list. `ListTopSort*` additionally sorts the returned values. The smallest values are selected by default. Thus, the functions without a suffix are the aliases to `*Asc` functions, while `*Desc` functions return the largest values.

`ListTopSort` is more effective than consecutive `ListTop` and `ListSort` because `ListTop` can partially sort the list to find needed values. However, `ListTop` is more effective than `ListTopSort` when the result order is unimportant.

Arguments:

1. List.
2. Size of selection.
3. An optional expression to get the sort key from a list element (it's the element itself by default).

Examples

```
ListTop(List<T>{Flags:AutoMap}, N)->List<T>
ListTop(List<T>{Flags:AutoMap}, N, (T)->U)->List<T>
```

The signatures of other functions are the same.

Functions for dictionaries

DictCreate

Construct an empty dictionary. Two arguments are passed: for a key and a value. Each argument specifies a string with the data type declaration or the type itself built by type functions. There are no dictionaries with an unknown key or value type in YQL. As a key, you can set a primitive data type, except for `Yson` and `Json` that may be optional or a tuple of them of a length of at least two.

Documentation for the type definition format.

Examples

```
SELECT DictCreate(String, Tuple<String,Double?>);
```

```
SELECT DictCreate(Tuple<Int32?,String>, OptionalType(DataType("String")));
```

SetCreate

Construct an empty set. An argument is passed: the key type that can be built by type functions. There are no sets with an unknown key type in YQL. As a key, you can set a primitive data type, except for `Yson` and `Json` that may be optional or a tuple of them of a length of at least two.

Documentation for the type definition format.

Examples

```
SELECT SetCreate(String);
```

```
SELECT SetCreate(Tuple<Int32?,String>);
```

DictLength

The count of items in the dictionary.

Examples

```
SELECT DictLength(AsDict(AsTuple(1, AsList("foo", "bar"))));
```

DictHasItems

Check that the dictionary contains at least one item.

Examples

```
SELECT DictHasItems(AsDict(AsTuple(1, AsList("foo", "bar")))) FROM my_table;
```

DictItems

Get dictionary contents as a list of tuples including key-value pairs (`List<Tuplekey_type,value_type>`).

Examples

```
SELECT DictItems(AsDict(AsTuple(1, AsList("foo", "bar"))));
-- [ ( 1, [ "foo", "bar" ] ) ]
```

DictKeys

Get a list of dictionary keys.

Examples

```
SELECT DictKeys(AsDict(AsTuple(1, AsList("foo", "bar"))));
-- [ 1 ]
```

DictPayloads

Get a list of dictionary values.

Examples

```
SELECT DictPayloads(AsDict(AsTuple(1, AsList("foo", "bar"))));
-- [ [ "foo", "bar" ] ]
```

DictLookup

Get a dictionary element by its key.

Examples

```
SELECT DictLookup(AsDict(
    AsTuple(1, AsList("foo", "bar")),
    AsTuple(2, AsList("bar", "baz"))
), 1);
-- [ "foo", "bar" ]
```

DictContains

Checking if an element in the dictionary using its key. Returns true or false.

Examples

```
SELECT DictContains(AsDict(
    AsTuple(1, AsList("foo", "bar")),
    AsTuple(2, AsList("bar", "baz"))
), 42);
-- false
```

DictAggregate

Apply aggregation factory to the passed dictionary where each value is a list. The factory is applied separately inside each key.
If the list is empty, the aggregation result is the same as for an empty table: 0 for the `COUNT` function and `NULL` for other functions.
If the list under a certain key is empty in the passed dictionary, such a key is removed from the result.
If the passed dictionary is optional and contains `NULL`, the result is also `NULL`.

Arguments:

1. Dictionary.
2. Aggregation factory.

Examples

```
SELECT DictAggregate(AsDict(
    AsTuple(1, AsList("foo", "bar")),
    AsTuple(2, AsList("baz", "qwe"))),
    AggregationFactory("Max"));
-- {1 : "foo", 2 : "qwe" }
```

SetIsDisjoint

Check that the dictionary doesn't intersect by keys with a list or another dictionary.

So there are two options to make a call:

- With the `Dict<K,V1>` and `List<K>` arguments.
- With the `Dict<K,V1>` and `Dict<K,V2>` arguments.

Examples

```
SELECT SetIsDisjoint(ToSet(AsList(1, 2, 3)), AsList(7, 4)); -- true
SELECT SetIsDisjoint(ToSet(AsList(1, 2, 3)), ToSet(AsList(3, 4))); -- false
```

SetIntersection

Construct intersection between two dictionaries based on keys.

Arguments:

- Two dictionaries: `Dict<K,V1>` and `Dict<K,V2>`.
- An optional function that combines the values from the source dictionaries to construct the values of the output dictionary. If such a function has the `(K,V1,V2) -> U` type, the result type is `Dict<K,U>`. If the function is not specified, the result type is `Dict<K,Void>`, and the values from the source dictionaries are ignored.

Examples

```
SELECT SetIntersection(ToSet(AsList(1, 2, 3)), ToSet(AsList(3, 4))); -- { 3 }
SELECT SetIntersection(
    AsDict(AsTuple(1, "foo"), AsTuple(3, "bar")),
    AsDict(AsTuple(1, "baz"), AsTuple(2, "qwe")),
    ($k, $a, $b) -> { RETURN AsTuple($a, $b) });
-- { 1 : ("foo", "baz") }
```

SetIncludes

Checking that the keys of the specified dictionary include all the elements of the list or the keys of the second dictionary.

So there are two options to make a call:

- With the `Dict<K,V1>` and `List<K>` arguments.
- With the `Dict<K,V1>` and `Dict<K,V2>` arguments.

Examples

```
SELECT SetIncludes(ToSet(AsList(1, 2, 3)), AsList(3, 4)); -- false
SELECT SetIncludes(ToSet(AsList(1, 2, 3)), ToSet(AsList(2, 3))); -- true
```

SetUnion

Constructs a union of two dictionaries based on keys.

Arguments:

- Two dictionaries: `Dict<K,V1>` and `Dict<K,V2>`.
- An optional function that combines the values from the source dictionaries to construct the values of the output dictionary. If such a function has the `(K,V1?,V2?) -> U` type, the result type is `Dict<K,U>`. If the function is not specified, the result type is `Dict<K,Void>`, and the values from the source dictionaries are ignored.

Examples

```
SELECT SetUnion(ToSet(AsList(1, 2, 3)), ToSet(AsList(3, 4))); -- { 1, 2, 3, 4 }
SELECT SetUnion(
    AsDict(AsTuple(1, "foo"), AsTuple(3, "bar")),
    AsDict(AsTuple(1, "baz"), AsTuple(2, "qwe")),
    ($k, $a, $b) -> { RETURN AsTuple($a, $b) });
-- { 1 : ("foo", "baz"), 2 : (null, "qwe"), 3 : ("bar", null) }
```

SetDifference

Construct a dictionary containing all the keys with their values in the first dictionary with no matching key in the second dictionary.

Examples

```
SELECT SetDifference(ToSet(AsList(1, 2, 3)), ToSet(AsList(3, 4))); -- { 1, 2 }
SELECT SetDifference(
    AsDict(AsTuple(1, "foo"), AsTuple(2, "bar")),
    ToSet(AsList(2, 3)));
-- { 1 : "foo" }
```

SetSymmetricDifference

Construct a symmetric difference between two dictionaries based on keys.

Arguments:

- Two dictionaries: `Dict<K,V1>` and `Dict<K,V2>`.
- An optional function that combines the values from the source dictionaries to construct the values of the output dictionary. If such a function has the `(K,V1?,V2?) -> U` type, the result type is `Dict<K,U>`. If the function is not specified, the result type is `Dict<K,Void>`, and the values from the source dictionaries are ignored.

Examples

```
SELECT SetSymmetricDifference(ToSet(AsList(1, 2, 3)), ToSet(AsList(3, 4))); -- { 1, 2, 4 }
SELECT SetSymmetricDifference(
    AsDict(AsTuple(1, "foo"), AsTuple(3, "bar")),
    AsDict(AsTuple(1, "baz"), AsTuple(2, "qwe")),
    ($k, $a, $b) -> { RETURN AsTuple($a, $b) });
-- { 2 : (null, "qwe"), 3 : ("bar", null) }
```

Functions for structures

TryMember

Trying to get a field from the structure. If it's not found among the fields or null in the structure value, use the default value.

Arguments:

1. Structure.
2. Field name.
3. Default value.

```
$struct = <|a:1|>;
SELECT
  TryMember(
    $struct,
    "a",
    123
  ) AS a, -- 1
  TryMember(
    $struct,
    "b",
    123
  ) AS b; -- 123
```

ExpandStruct

Adding one or more new fields to the structure.

If the field set contains duplicate values, an error is returned.

Arguments:

- The first argument passes the source structure to be expanded.
- All the other arguments must be named, each argument adds a new field and the argument's name is used as the field's name (as in AsStruct).

Examples

```
$struct = <|a:1|>;
SELECT
  ExpandStruct(
    $struct,
    2 AS b,
    "3" AS c
  ) AS abc;
```

AddMember

Adding one new field to the structure. If you need to add multiple fields, better use ExpandStruct.

If the field set contains duplicate values, an error is returned.

Arguments:

1. Source structure.
2. Name of the new field.
3. Value of the new field.

Examples

```
$struct = <|a:1|>;
SELECT
  AddMember(
    $struct,
    "b",
    2
  ) AS ab;
```

RemoveMember

Removing a field from the structure.

If the entered field hasn't existed, an error is returned.

Arguments:

1. Source structure.
2. Field name.

Examples

```
$struct = <|a:1, b:2|>;
SELECT
  RemoveMember(
    $struct,
    "b"
  ) AS a;
```

ForceRemoveMember

Removing a field from the structure.

If the entered field hasn't existed, unlike RemoveMember, the error is not returned.

Arguments:

1. Source structure.
2. Field name.

Examples

```
$struct = <|a:1, b:2|>;
SELECT
  ForceRemoveMember(
    $struct,
    "c"
  ) AS ab;
```

ChooseMembers

Selecting fields with specified names from the structure.

If any of the fields haven't existed, an error is returned.

Arguments:

1. Source structure.
2. List of field names.

Examples

```
$struct = <|a:1, b:2, c:3|>;
SELECT
  ChooseMembers(
    $struct,
    ["a", "b"]
  ) AS ab;
```

RemoveMembers

Excluding fields with specified names from the structure.

If any of the fields haven't existed, an error is returned.

Arguments:

1. Source structure.
2. List of field names.

Examples

```
$struct = <|a:1, b:2, c:3|>;
SELECT
  RemoveMembers(
    $struct,
    ["a", "b"]
  ) AS c;
```

ForceRemoveMembers

Excluding fields with specified names from the structure.

If any of the fields haven't existed, it is ignored.

Arguments:

1. Source structure.
2. List of field names.

Examples

```
$struct = <|a:1, b:2, c:3|>;
SELECT
  ForceRemoveMembers(
    $struct,
    ["a", "b", "z"]
  ) AS c;
```

CombineMembers

Combining the fields from multiple structures into a new structure.

If the resulting field set contains duplicate values, an error is returned.

Arguments: two or more structures.

Examples

```
$struct1 = <|a:1, b:2|>;
$struct2 = <|c:3|>;
SELECT
  CombineMembers(
    $struct1,
    $struct2
  ) AS abc;
```

FlattenMembers

Combining the fields from multiple new structures into another new structure with prefix support.

If the resulting field set contains duplicate values, an error is returned.

Arguments: two or more tuples of two items: prefix and structure.

Examples

```
$struct1 = <|a:1, b:2|>;
$struct2 = <|c:3|>;
SELECT
  FlattenMembers(
    AsTuple("foo", $struct1), -- fooa, foob
    AsTuple("bar", $struct2)  -- barc
  ) AS abc;
```

StructMembers

Returns an unordered list of field names (possibly removing one Optional level) for a single argument that is a structure. For the `NULL` argument, an empty list of strings is returned.

Argument: structure

Examples

```
$struct = <|a:1, b:2|>;
SELECT
  StructMembers($struct); -- ['a', 'b']
```

RenameMembers

Renames the fields in the structure passed. In this case, you can rename a source field into multiple target fields. All fields not mentioned in the renaming as source names are moved to the result structure. If some source field is omitted in the rename list, an error is returned. For an Optional structure or `NULL`, the result has the same type.

Arguments:

1. Source structure.
2. A tuple of field names: the original name, the new name.

Examples

```
$struct = <|a:1, b:2|>;
SELECT
  RenameMembers($struct, [('a', 'c'), ('a', 'e')]); -- (b:2, c:1, e:1)
```

ForceRenameMembers

Renames the fields in the structure passed. In this case, you can rename a source field into multiple target fields. All fields not mentioned in the renaming as source names are moved to the result structure. If some source field is omitted in the rename list, the name is ignored. For an Optional structure or `NULL`, the result has the same type.

Arguments:

1. Source structure.
2. A tuple of field names: the original name, the new name.

Examples

```
$struct = <|a:1, b:2|>;
SELECT
  ForceRenameMembers($struct, [('a', 'c'), ('d', 'e')]); -- (b:2, c:1)
```

GatherMembers

Returns an unordered list of tuples including the field name and value. For the `NULL` argument, `EmptyList` is returned. It can be used only in the cases when the types of items in the structure are the same or compatible. Returns an optional list for an optional structure.

Argument: structure

Examples

```
$struct = <|a:1, b:2|>;
SELECT
  GatherMembers($struct); -- [('a', 1), ('b', 2)]
```

SpreadMembers

Creates a structure with a specified list of fields and applies a specified list of edits to it in the format (field name, field value). All types of fields in the resulting structure are the same and equal to the type of values in the update list with added Optional (unless they are optional already). If the field wasn't mentioned among the list of updated fields, it's returned as `NULL`. Among all updates for a field, the latest one is written. If the update list is Optional or `NULL`, the result has the same type. If the list of edits includes a field that is not in the list of expected fields, an error is returned.

Arguments:

1. List of tuples: field name, field value.
2. A list of all possible field names in the structure.

Examples

```
SELECT
  SpreadMembers([('a',1),('a',2)],['a','b']); -- (a: 2, b: null)
```

ForceSpreadMembers

Creates a structure with a specified list of fields and applies to it the specified list of updates in the format (field name, field value). All types of fields in the resulting structure are the same and equal to the type of values in the update list with added Optional (unless they are optional already). If the field wasn't mentioned among the list of updated fields, it's returned as `NULL`. Among all updates for a field, the latest one is written. If the update list is optional or equal to `NULL`, the result has the same type. If the list of updates includes a field that is not in the list of expected fields, this edit is ignored.

Arguments:

1. List of tuples: field name, field value.
2. A list of all possible field names in the structure.

Examples

```
SELECT
  ForceSpreadMembers([('a',1),('a',2),('c',100)],['a','b']); -- (a: 2, b: null)
```

StructUnion, StructIntersection, StructDifference, StructSymmetricDifference

Combine two structures using one of the four methods (using the provided lambda to merge fields with the same name):

- `StructUnion` adds all fields of both of the structures to the result.
- `StructIntersection` adds only the fields which are present in both of the structures.
- `StructDifference` adds only the fields of `left`, which are absent in `right`.
- `StructSymmetricDifference` adds all fields that are present in exactly one of the structures.

Signatures

```
StructUnion(left:Struct<...>, right:Struct<...>[, mergeLambda:(name:String, l:T1?, r:T2?)->T])->Struct<...>
StructIntersection(left:Struct<...>, right:Struct<...>[, mergeLambda:(name:String, l:T1?, r:T2?)->T])->Struct
<...>
StructDifference(left:Struct<...>, right:Struct<...>)->Struct<...>
StructSymmetricDifference(left:Struct<...>, right:Struct<...>)->Struct<...>
```

Arguments:

1. `left` - first structure.
2. `right` - second structure.
3. `mergeLambda` - *(optional)* function to merge fields with the same name (arguments: field name, `Optional` field value of the first struct, `Optional` field value of the second struct - arguments are `Nothing<T?>` in case of absence of the corresponding struct field). By default, if present, the first structure's field value is used; otherwise, the second one's value is used.

Examples

```
$merge = ($name, $l, $r) -> {
    return ($l ?? 0) + ($r ?? 0);
};
$left = <|a: 1, b: 2, c: 3|>;
$right = <|c: 1, d: 2, e: 3|>;

SELECT
    StructUnion($left, $right),                 -- <|a: 1, b: 2, c: 3, d: 2, e: 3|>
    StructUnion($left, $right, $merge),         -- <|a: 1, b: 2, c: 4, d: 2, e: 3|>
    StructIntersection($left, $right, $merge),  -- <|c: 4|>
    StructDifference($left, $right),            -- <|a: 1, b: 1|>
    StructSymmetricDifference($left, $right)    -- <|a: 1, b: 2, d: 2, e: 3|>
;
```

Functions for data types

FormatType

Serializing a type or a handle type to a human-readable string. This helps at debugging and will also be used in the next examples of this section. Documentation for the format.

ParseType

Building a type from a string with description. Documentation for its format.

Examples

```
SELECT FormatType(ParseType("List<Int32>"));  -- List<int32>
```

TypeOf

Getting the type of value passed to the argument.

Examples

```
SELECT FormatType(TypeOf("foo"));  -- String
```

```
SELECT FormatType(TypeOf(AsTuple(1, 1u))); -- Tuple<Int32,Uint32>
```

InstanceOf

Returns an instance of the specified type that can only be used to get the type of the result of an expression that uses this type.

If this instance remains in the computation graph by the end of optimization, the operation fails.

Examples

```
SELECT FormatType(TypeOf(
    InstanceOf(ParseType("Int32")) +
    InstanceOf(ParseType("Double"))
)); -- Double, because "Int32 + Double" returns Double
```

DataType

Returns a type for primitive data types based on type name.

Examples

```
SELECT FormatType(DataType("Bool")); -- Bool
SELECT FormatType(DataType("Decimal","5","1")); -- Decimal(5,1)
```

OptionalType

Adds the option to assign `NULL` to the passed type.

Examples

```
SELECT FormatType(OptionalType(DataType("Bool"))); -- Bool?
```

ListType and StreamType

Builds a list type or stream type based on the passed element type.

Examples

```
SELECT FormatType(ListType(DataType("Bool"))); -- List<Bool>
```

DictType

Builds a dictionary type based on the passed key types (first argument) and value types (second argument).

Examples

```
SELECT FormatType(DictType(
    DataType("String"),
    DataType("Double")
)); -- Dict<String,Double>
```

TupleType

Builds the tuple type from the passed element types.

Examples

```
SELECT FormatType(TupleType(
    DataType("String"),
    DataType("Double"),
    OptionalType(DataType("Bool"))
)); -- Tuple<String,Double,Bool?>
```

StructType

Builds the structure type based on the passed element types. The standard syntax of named arguments is used to specify the element names.

Examples

```
SELECT FormatType(StructType(
    DataType("Bool") AS MyBool,
    ListType(DataType("String")) AS StringList
)); -- Struct<'MyBool':Bool,'StringList':List<String>>
```

VariantType

Returns the type of a variant based on the underlying type (structure or tuple).

Examples

```
SELECT FormatType(VariantType(
  ParseType("Struct<foo:Int32,bar:Double>")
)); -- Variant<'bar':Double,'foo':Int32>
```

ResourceType

Returns the type of the resource based on the passed string label.

Examples

```
SELECT FormatType(ResourceType("Foo")); -- Resource<'Foo'>
```

CallableType

Constructs the type of the called value using the following arguments:

1. Number of optional arguments (if all arguments are required — 0).
2. Result type.
3. All the next arguments of CallableType are treated as types of arguments of the callable value, but with a shift for two required arguments (for example, the third argument of the CallableType describes the type of the first argument in the callable value).

Examples

```
SELECT FormatType(CallableType(
  1, -- optional args count
  DataType("Double"), -- result type
  DataType("String"), -- arg #1 type
  OptionalType(DataType("Int64")) -- arg #2 type
)); -- Callable<(String,[Int64?])->Double>
```

GenericType, UnitType, and VoidType

Return the same-name special data types. They have no arguments because they are not parameterized.

Examples

```
SELECT FormatType(VoidType()); -- Void
```

OptionalItemType, ListItemType and StreamItemType

If a type is passed to these functions, then they perform the action reverse to OptionalType, ListType, and StreamType: return the item type based on its container type.

If a type handle is passed to these functions, then they perform the action reverse to OptionalTypeHandle, ListTypeHandle, and StreamTypeHandle: they return the handle of the element type based on the type handle of its container.

Examples

```
SELECT FormatType(ListItemType(
  ParseType("List<Int32>")
)); -- Int32
```

```
SELECT FormatType(ListItemType(
  ParseTypeHandle("List<Int32>")
)); -- Int32
```

DictKeyType and DictPayloadType

Returns the type of the key or value based on the dictionary type.

Examples

```
SELECT FormatType(DictKeyType(
  ParseType("Dict<Int32,String>")
)); -- Int32
```

TupleElementType

Returns the tuple's element type based on the tuple type and the element index (index starts from zero).

Examples

```
SELECT FormatType(TupleElementType(
  ParseType("Tuple<Int32,Double>"), "1"
)); -- Double
```

StructMemberType

Returns the type of the structure element based on the structure type and element name.

Examples

```
SELECT FormatType(StructMemberType(
  ParseType("Struct<foo:Int32,bar:Double>"), "foo"
)); -- Int32
```

CallableResultType and CallableArgumentType

`CallableResultType` returns the result type based on the type of the called value. `CallableArgumentType` returns the argument type based on the called value type and its index (index starts from zero).

Examples

```
$callable_type = ParseType("(String,Bool)->Double");

SELECT FormatType(CallableResultType(
    $callable_type
)), -- Double
FormatType(CallableArgumentType(
    $callable_type, 1
)); -- Bool
```

VariantUnderlyingType

If a type is passed to this function, then it an action reverse to VariantType: it returns the underlying type based on the variant type.

If a type handle is passed to this function, it performs the action reverse to VariantTypeHandle: returns the handle of the underlying type based on the handle of the variant type.

Examples

```
SELECT FormatType(VariantUnderlyingType(
  ParseType("Variant<foo:Int32,bar:Double>")
)), -- Struct<'bar':Double,'foo':Int32>
FormatType(VariantUnderlyingType(
  ParseType("Variant<Int32,Double>")
)); -- Tuple<Int32,Double>
```

```
SELECT FormatType(VariantUnderlyingType(
  ParseTypeHandle("Variant<foo:Int32,bar:Double>")
)), -- Struct<'bar':Double,'foo':Int32>
FormatType(VariantUnderlyingType(
  ParseTypeHandle("Variant<Int32,Double>")
)); -- Tuple<Int32,Double>
```

Functions for data types during calculations

To work with data types during calculations, use handle types: these are resources that contain an opaque type definition. After constructing the type handle, you can revert to the regular type using the EvaluateType function. For debug purposes, you can convert a handle type to a string using the FormatType function.

TypeHandle

Getting a type handle from the type passed to the argument.

Examples

```
SELECT FormatType(TypeHandle(TypeOf("foo")));  -- String
```

EvaluateType

Getting the type from the type handle passed to the argument. The function is evaluated before the start of the main calculation, as well as EvaluateExpr.

Examples

```
SELECT FormatType(EvaluateType(TypeHandle(TypeOf("foo"))));  -- String
```

ParseTypeHandle

Building a type handle from a string with description. Documentation for its format.

Examples

```
SELECT FormatType(ParseTypeHandle("List<Int32>"));  -- List<int32>
```

TypeKind

Getting the top-level type name from the type handle passed to the argument.

Examples

```
SELECT TypeKind(TypeHandle(TypeOf("foo")));  -- Data
SELECT TypeKind(ParseTypeHandle("List<Int32>"));  -- List
```

DataTypeComponents

Getting the name and parameters for a primitive data type from the primitive type handle passed to the argument. Reverse function: DataTypeHandle.

Examples

```
SELECT DataTypeComponents(TypeHandle(TypeOf("foo")));  -- ["String"]
SELECT DataTypeComponents(ParseTypeHandle("Decimal(4,1)"));  -- ["Decimal", "4", "1"]
```

DataTypeHandle

Constructing a handle for a primitive data type from its name and parameters passed to the argument as a list. Reverse function: DataTypeComponents.

Examples

```
SELECT FormatType(DataTypeHandle(
    AsList("String")
)); -- String

SELECT FormatType(DataTypeHandle(
    AsList("Decimal", "4", "1")
)); -- Decimal(4,1)
```

OptionalTypeHandle

Adds the option to assign `NULL` to the passed type handle.

Examples

```
SELECT FormatType(OptionalTypeHandle(
    TypeHandle(DataType("Bool"))
)); -- Bool?
```

PgTypeName

Getting the name of the PostgreSQL type from the type handle passed to the argument. Inverse function: PgTypeHandle.

Examples

```
SELECT PgTypeName(ParseTypeHandle("pgint4")); -- int4
```

PgTypeHandle

Builds a type handle based on the passed name of the PostgreSQL type. Inverse function: PgTypeName.

Examples

```
SELECT FormatType(PgTypeHandle("int4")); -- pgint4
```

ListTypeHandle and StreamTypeHandle

Builds a list type handle or stream type handle based on the passed element type handle.

Examples

```
SELECT FormatType(ListTypeHandle(
    TypeHandle(DataType("Bool"))
)); -- List<Bool>
```

EmptyListTypeHandle and EmptyDictTypeHandle

Constructs a handle for an empty list or dictionary.

Examples

```
SELECT FormatType(EmptyListTypeHandle()); -- EmptyList
```

TupleTypeComponents

Getting a list of element type handles from the tuple type handle passed to the argument. Inverse function: TupleTypeHandle.

Examples

```
SELECT ListMap(
   TupleTypeComponents(
       ParseTypeHandle("Tuple<Int32, String>")
   ),
   ($x)->{
       return FormatType($x)
   }
); -- ["Int32", "String"]
```

TupleTypeHandle

Building a tuple type handle from handles of element types passed as a list to the argument. Inverse function: TupleTypeComponents.

Examples

```
SELECT FormatType(
    TupleTypeHandle(
        AsList(
            ParseTypeHandle("Int32"),
            ParseTypeHandle("String")
        )
    )
); -- Tuple<Int32,String>
```

StructTypeComponents

Getting a list of element type handles and their names from the structure type handle passed to the argument. Inverse function: StructTypeHandle.

Examples

```
SELECT ListMap(
    StructTypeComponents(
        ParseTypeHandle("Struct<a:Int32, b:String>")
    ),
    ($x) -> {
        return AsTuple(
            FormatType($x.Type),
            $x.Name
        )
    }
); -- [("Int32","a"), ("String","b")]
```

StructTypeHandle

Building a structure type handle from handles of element types and names passed as a list to the argument. Inverse function: StructTypeComponents.

Examples

```
SELECT FormatType(
    StructTypeHandle(
        AsList(
            AsStruct(ParseTypeHandle("Int32") as Type,"a" as Name),
            AsStruct(ParseTypeHandle("String") as Type, "b" as Name)
        )
    )
); -- Struct<'a':Int32,'b':String>
```

DictTypeComponents

Getting a key-type handle and a value-type handle from the dictionary-type handle passed to the argument. Inverse function: DictTypeHandle.

Examples

```
$d = DictTypeComponents(ParseTypeHandle("Dict<Int32,String>"));

SELECT
    FormatType($d.Key),     -- Int32
    FormatType($d.Payload); -- String
```

DictTypeHandle

Building a dictionary-type handle from a key-type handle and a value-type handle passed to arguments. Inverse function: DictTypeComponents.

Examples

```
SELECT FormatType(
    DictTypeHandle(
        ParseTypeHandle("Int32"),
        ParseTypeHandle("String")
    )
); -- Dict<Int32, String>
```

ResourceTypeTag

Getting the tag from the resource type handle passed to the argument. Inverse function: ResourceTypeHandle.

Examples

```
SELECT ResourceTypeTag(ParseTypeHandle("Resource<foo>")); -- foo
```

ResourceTypeHandle

Building a resource-type handle from the tag value passed to the argument. Inverse function: ResourceTypeTag.

Examples

```
SELECT FormatType(ResourceTypeHandle("foo")); -- Resource<'foo'>
```

TaggedTypeComponents

Getting the tag and the basic type from the decorated type handle passed to the argument. Inverse function: TaggedTypeHandle.

Examples

```
$t = TaggedTypeComponents(ParseTypeHandle("Tagged<Int32,foo>"));

SELECT FormatType($t.Base), $t.Tag; -- Int32, foo
```

TaggedTypeHandle

Constructing a decorated type handle based on the base type handle and the tag name passed in arguments. Inverse function: TaggedTypeComponents.

Examples

```
SELECT FormatType(TaggedTypeHandle(
    ParseTypeHandle("Int32"), "foo"
)); -- Tagged<Int32, 'foo'>
```

VariantTypeHandle

Building a variant-type handle from the handle of the underlying type passed to the argument. Inverse function: VariantUnderlyingType.

Examples

```
SELECT FormatType(VariantTypeHandle(
    ParseTypeHandle("Tuple<Int32, String>")
)); -- Variant<Int32, String>
```

VoidTypeHandle and NullTypeHandle

Constructing a handle for Void and Null types, respectively.

Examples

```
SELECT FormatType(VoidTypeHandle()); -- Void
SELECT FormatType(NullTypeHandle()); -- Null
```

CallableTypeComponents

Getting the handle description for the type of callable value passed to the argument. Inverse function: CallableTypeHandle.

Examples

```
$formatArgument = ($x) -> {
    return AsStruct(
        FormatType($x.Type) as Type,
        $x.Name as Name,
        $x.Flags as Flags
    )
};

$formatCallable = ($x) -> {
    return AsStruct(
        $x.OptionalArgumentsCount as OptionalArgumentsCount,
        $x.Payload as Payload,
        FormatType($x.Result) as Result,
        ListMap($x.Arguments, $formatArgument) as Arguments
    )
};

SELECT $formatCallable(
    CallableTypeComponents(
        ParseTypeHandle("(Int32,[bar:Double?{Flags:AutoMap}])->String")
    )
);  -- (OptionalArgumentsCount: 1, Payload: "", Result: "String", Arguments: [
    --   (Type: "Int32", Name: "", Flags: []),
    --   (Type: "Double?", Name: "bar", Flags: ["AutoMap"]),
    -- ])
```

CallableArgument

Packing the description of the argument of the callable value into the structure to be passed to the CallableTypeHandle function with the following arguments:

1. Argument type handle.
2. Optional argument name. The default value is an empty string.
3. A list of strings with optional argument flags. The default value is an empty list. Supported flags are "AutoMap".

CallableTypeHandle

Constructing the type handle of the called value using the following arguments:

1. Handle of the return value type.
2. List of descriptions of arguments received using the CallableArgument function.
3. Optional number of optional arguments in the callable value. The default value is 0.
4. An optional label for the called value type. The default value is an empty string.

Inverse function: CallableTypeComponents.

Examples

```
SELECT FormatType(
    CallableTypeHandle(
        ParseTypeHandle("String"),
        AsList(
            CallableArgument(ParseTypeHandle("Int32")),
            CallableArgument(ParseTypeHandle("Double?"), "bar", AsList("AutoMap"))
        ),
        1
    )
);  -- Callable<(Int32,['bar':Double?{Flags:AutoMap}])->String>
```

LambdaArgumentsCount

Getting the number of arguments in a lambda function.

Examples

```
SELECT LambdaArgumentsCount(($x, $y)->($x+$y))
; -- 2
```

Functions for code generation

When running calculations, you can generate the code including S-expressions nodes. This uses a mechanism for packing the code in the resource. After building the code, you can insert it into the main program using the EvaluateCode function. For debugging purposes, you can convert the code to a string using the FormatCode function.

Possible node types in S-expressions that can be used for code generation:

- An atom is an untyped string of zero or more characters.
- A list is a sequence of zero or more nodes. It corresponds to the `tuple` type in SQL.
- A call of a built-in function consists of a name expressed by an atom and a sequence of zero or more nodes that are arguments to this function.
- Lambda function declaration consists of declaring the names of arguments and a node that is the root of the body for this lambda function.
- The lambda function argument is a node that can only be used inside the body of the lambda function.
- World is a special node that labels I/O operations.

The S-expressions nodes form a directed graph. Atoms are always leaf nodes, because they cannot contain child nodes.

In the text representation, S-expressions have the following format:

- Atom: `'"foo"`. The apostrophe character (') denotes quoting of the next line that is usually enclosed in quotation marks.
- List: `'("foo" "bar")`. The apostrophe character (') denotes that there will be no function call in parentheses.
- Calling the built-in function: `(foo "bar")`. The first item inside the brackets is the mandatory name of the function followed by the function arguments.
- Declaring a lambda function: `(lambda '(x y) (+ x y))`. The `lambda` keyword is followed by a list of argument names and then by the body of the lambda function.
- The lambda function argument is `x`. Unlike an atom, a string without an apostrophe character (') references a name in the current scope. When declaring a lambda function, the names of arguments are added to the body's visibility scope, and, if needed, the name is hidden from the global scope.
- The `world`.

FormatCode

Serializing the code as S-expressions. The code must not contain free arguments of functions, hence, to serialize the lambda function code, you must pass it completely, avoiding passing individual expressions that might contain lambda function arguments.

Examples

```
SELECT FormatCode(AtomCode("foo"));
-- (
-- (return '"foo")
-- )
```

WorldCode

Build a code node with the `world` type.

Examples

```
SELECT FormatCode(WorldCode());
-- (
-- (return world)
-- )
```

AtomCode

Build a code node with the `atom` type from a string passed to the argument.

Examples

```
SELECT FormatCode(AtomCode("foo"));
-- (
-- (return '"foo")
-- )
```

ListCode

Build a code node with the `list` type from a set of nodes or lists of code nodes passed to arguments. In this case, lists of arguments are built in as separately listed code nodes.

Examples

```
SELECT FormatCode(ListCode(
    AtomCode("foo"),
    AtomCode("bar")));
-- (
-- (return '('"foo" '"bar"))
-- );

SELECT FormatCode(ListCode(AsList(
    AtomCode("foo"),
    AtomCode("bar"))));
-- (
-- (return '('"foo" '"bar"))
-- )
```

FuncCode

Build a code node with the `built-in function call` from a string with the function name and a set of nodes or lists of code nodes passed to arguments. In this case, lists of arguments are built in as separately listed code nodes.

Examples

```
SELECT FormatCode(FuncCode(
    "Baz",
    AtomCode("foo"),
    AtomCode("bar")));
-- (
-- (return (Baz '"foo" '"bar"))
-- )

SELECT FormatCode(FuncCode(
    "Baz",
    AsList(
        AtomCode("foo"),
        AtomCode("bar"))));
-- (
-- (return (Baz '"foo" '"bar"))
-- )
```

LambdaCode

You can build a code node with the `lambda function declaration` type from:

- a Lambda function, if you know the number of arguments in advance. In this case, the nodes of the `argument` type will be passed as arguments to this lambda function.
- The number of arguments and a lambda function with one argument. In this case, a list of nodes of the `argument` type will be passed as an argument to this lambda function.

Examples

```
SELECT FormatCode(LambdaCode(($x, $y) -> {
    RETURN FuncCode("+", $x, $y);
}));
-- (
-- (return (lambda '($1 $2) (+ $1 $2)))
-- )

SELECT FormatCode(LambdaCode(2, ($args) -> {
    RETURN FuncCode("*", Unwrap($args[0]), Unwrap($args[1]));
}));
-- (
-- (return (lambda '($1 $2) (* $1 $2)))
-- )
```

EvaluateCode

Substituting the code node passed in the argument, into the main program code.

Examples

```
SELECT EvaluateCode(FuncCode("Int32", AtomCode("1"))); -- 1

$lambda = EvaluateCode(LambdaCode(($x, $y) -> {
    RETURN FuncCode("+", $x, $y);
}));
SELECT $lambda(1, 2); -- 3
```

ReprCode

Substituting the code node representing the result of evaluating an expression passed in the argument, into the main program.

Examples

```
$add3 = EvaluateCode(LambdaCode(($x) -> {
    RETURN FuncCode("+", $x, ReprCode(1 + 2));
}));
SELECT $add3(1); -- 4
```

QuoteCode

Substituting into the main program the code node that represents an expression or a lambda function passed in the argument. If free arguments of lambda functions were found during the substitution, they are calculated and substituted into the code as in the ReprCode function.

Examples

```
$lambda = ($x, $y) -> { RETURN $x + $y };
$makeClosure = ($y) -> {
    RETURN EvaluateCode(LambdaCode(($x) -> {
        RETURN FuncCode("Apply", QuoteCode($lambda), $x, ReprCode($y))
    }))
};

$closure = $makeClosure(2);
SELECT $closure(1); -- 3
```

Functions for JSON

JSON is a lightweight data-interchange format. In YQL, it's represented by the `Json` type. Unlike relational tables, JSON can store data with no schema defined. Here is an example of a valid JSON object:

```
[
    {
        "name": "Jim Holden",
        "age": 30
    },
    {
        "name": "Naomi Nagata",
        "age": "twenty years old"
    }
]
```

Despite the fact that the `age` field in the first object is of the `Number` type (`"age": 21`) and in the second object its type is `String` (`"age": "twenty years old"`), this is a fully valid JSON object.

To work with JSON, YQL implements a subset of the SQL support for JavaScript Object Notation (JSON) standard, which is part of the common ANSI SQL standard.

JsonPath

Values inside JSON objects are accessed using a query language called JsonPath. All functions for JSON accept a JsonPath query as an argument.

Let's look at an example. Suppose we have a JSON object like:

```
{
    "comments": [
        {
            "id": 123,
            "text": "A whisper will do, if it's all that you can manage."
        },
        {
            "id": 456,
            "text": "My life has become a single, ongoing revelation that I haven’t been cynical enough."
        }
    ]
}
```

Then, to get the text of the second comment, we can write the following JsonPath query:

```
$.comments[1].text
```

In this query:

1. `$` is a way to access the entire JSON object.
2. `$.comments` accesses the `comments` key of the JSON object.
3. `$.comments[1]` accesses the second element of the JSON array (element numbering starts from 0).
4. `$.comments[1].text` accesses the `text` key of the JSON object.
5. Query execution result: `"My life has become a single, ongoing revelation that I haven’t been cynical enough."`

Quick reference

Operation	Example
Retrieving a JSON object key	`$.key`
Retrieving all JSON object keys	`$.*`
Accessing an array element	`$[25]`
Retrieving an array subsegment	`$[2 to 5]`
Accessing the last array element	`$[last]`
Accessing all array elements	`$[*]`
Unary operations	`- 1`
Binary operations	`(12 * 3) % 4 + 8`
Accessing a variable	`$variable`
Logical operations	`(1 > 2) || (3 <= 4) && ("string" == "another")|`
Matching a regular expression	`$.name like_regex "^[A-Za-z]+$"`
Checking the string prefix	`$.name starts with "Bobbie"`
Checking if a path exists	`exists ($.profile.name)`
Checking a Boolean expression for null	`($.age > 20) is unknown`
Filtering values	`$.friends ? (@.age >= 18 && @.gender == "male")`

Getting the value type	`$.name.type()`
Getting the array size	`$.friends.size()`
Converting a string to a number	`$.number.double()`
Rounding up a number	`$.number.ceiling()`
Rounding down a number	`$.number.floor()`
Returning the absolute value	`$.number.abs()`
Getting key-value pairs from an object	`$.profile.keyvalue()`

Data model

The result of executing all JsonPath expressions is a sequence of JSON values. For example:

- The result of executing the `"Bobbie"` expression is a sequence with the only element `"Bobbie"`. Its length is 1.
- The result of executing the `$` expression (that takes the entire JSON object) in JSON `[1, 2, 3]` is `[1, 2, 3]`. A sequence of 1 element of the array `[1, 2, 3]`
- The result of executing the `$[*]` expression (retrieving all array elements) in JSON `[1, 2, 3]` is `1, 2, 3`. A sequence of three items: `1`, `2`, and `3`

If the input sequence consists of multiple values, some operations are performed for each element (for example, accessing a JSON object key). However, other operations require a sequence of one element as input (for example, binary arithmetic operations).

The behavior of a specific operation is described in the corresponding section of the documentation.

Execution mode

JsonPath supports two execution modes, `lax` and `strict`. Setting the mode is optional. By default, `lax`. The mode is specified at the beginning of a query. For example, `strict $.key`.

The behavior for each mode is described in the corresponding sections with JsonPath operations.

Auto unpacking of arrays

When accessing a JSON object key in `lax` mode, arrays are automatically unpacked.

Example

```
[
    {
        "key": 123
    },
    {
        "key": 456
    }
]
```

The `lax $.key` query is successful and returns `123, 456`. As `$` is an array, it's automatically unpacked and accessing the key of the `$.key` JSON object is executed for each element in the array.

The `strict $.key` query returns an error. In `strict` mode, there is no support for auto unpacking of arrays. Since `$` is an array and not an object, accessing the `$.key` object key is impossible. You can fix this by writing `strict $[*].key`.

Unpacking is only 1 level deep. In the event of nested arrays, only the outermost one is unpacked.

Wrapping values in arrays

When accessing an array element in `lax` mode, JSON values are automatically wrapped in an array.

Example

```
{
    "name": "Avasarala"
}
```

The `lax $[0].name` query is successful and returns `"Avasarala"`. As `$` isn't an array, it's automatically wrapped in an array of length 1. Accessing the first element `$[0]` returns the source JSON object where the `name` key is taken.

The `strict $[0].name` query returns an error. In `strict` mode, values aren't wrapped in an array automatically. Since `$` is an object and not an array, accessing the `$[0]` element is impossible. You can fix this by writing `strict $.name`.

Handling errors

Some errors are converted to an empty result when a query is executed in `lax` mode.

Literals

Values of some types can be specified in a JsonPath query using literals:

Type	Example
Numbers	`42`, `-1.23e-5`
Boolean values	`false`, `true`
Null	`Null`

Stings	`"Belt"`

Accessing JSON object keys

JsonPath supports accessing JSON object keys, such as `$.session.user.name`.

> **Note**
>
> Accessing keys without quotes is only supported for keys that start with an English letter or underscore and only contain English letters, underscores, numbers, and a dollar sign. Use quotes for all other keys. For example, `$.profile."this string has spaces"` or `$.user."42 is the answer"`

For each value from the input sequence:

1. If the value is an array, it's automatically unpacked in `lax` mode.
2. If the value isn't a JSON object or if it is and the specified key is missing from this JSON object, a query executed in `strict` mode fails. In `lax` mode, an empty result is returned for this value.

The expression execution result is the concatenation of the results for each value from the input sequence.

Example

```
{
    "name": "Amos",
    "friends": [
        {
            "name": "Jim"
        },
        {
            "name": "Alex"
        }
    ]
}
```

	`lax`	`strict`
`$.name`	`"Amos"`	`"Amos"`
`$.surname`	Empty result	Error
`$.friends.name`	`"Jim", "Alex"`	Error

Accessing all JSON object keys

JsonPath supports accessing all JSON object keys at once: `$.*`.

For each value from the input sequence:

1. If the value is an array, it's automatically unpacked in `lax` mode.
2. If the value isn't a JSON object, a query executed in `strict` mode fails. In `lax` mode, an empty result is returned for this value.

The expression execution result is the concatenation of the results for each value from the input sequence.

Example

```
{
    "profile": {
        "id": 123,
        "name": "Amos"
    },
    "friends": [
        {
            "name": "Jim"
        },
        {
            "name": "Alex"
        }
    ]
}
```

	`lax`	`strict`
`$.profile.*`	`123, "Amos"`	`123, "Amos"`
`$.friends.*`	`"Jim", "Alex"`	Error

Accessing an array element

JsonPath supports accessing array elements: `$.friends[1, 3 to last - 1]`.

For each value from the input sequence:

1. If the value isn't an array, a query executed in `strict` mode fails. In `lax` mode, values are automatically wrapped in an array.
2. The `last` keyword is replaced with the array's last index. Using `last` outside of accessing the array is an error in both modes.
3. The specified indexes are calculated. Each of them must be a single number, otherwise the query fails in both modes.

4. If the index is a fractional number, it's rounded down.
5. If the index goes beyond the array boundaries, the query executed in `strict` mode fails. In `lax` mode, this index is ignored.
6. If a segment is specified and its start index is greater than the end index (for example, `$[20 to 1]`), the query fails in `strict` mode. In `lax` mode, this segment is ignored.
7. All elements by the specified indexes are added to the result. Segments include **both ends**.

Examples

```
[
    {
        "name": "Camina",
        "surname": "Drummer"
    },
    {
        "name": "Josephus",
        "surname": "Miller"
    },
    {
        "name": "Bobbie",
        "surname": "Draper"
    },
    {
        "name": "Julie",
        "surname": "Mao"
    }
]
```

	`lax`	`strict`
`$[0].name`	`"Camina"`	`"Camina"`
`$[1, 2 to 3].name`	`"Josephus", "Bobbie", "Julie"`	`"Josephus", "Bobbie", "Julie"`
`$[last - 2].name`	`"Josephus"`	`"Josephus"`
`$[2, last + 200 to 50].name`	`"Bobbie"`	Error
`$[50].name`	Empty result	Error

Accessing all array elements

JsonPath supports accessing all array elements at once: `$[*]`.

For each value from the input sequence:

1. If the value isn't an array, a query executed in `strict` mode fails. In `lax` mode, values are automatically wrapped in an array.
2. All elements of the current array are added to the result.

Examples

```
[
    {
        "class": "Station",
        "title": "Medina"
    },
    {
        "class": "Corvette",
        "title": "Rocinante"
    }
]
```

	`lax`	`strict`
`$[*].title`	`"Medina", "Rocinante"`	`"Medina", "Rocinante"`
`lax $[0][*].class`	`"Station"`	Error

Let's analyze the last example step by step:

1. `$[0]` returns the first element of the array, that is `{"class": "Station", "title": "Medina"}`
2. `$[0][*]` expects an array for input, but an object was input instead. It's automatically wrapped in an array as `[ {"class": "Station", "title": "Medina"} ]`
3. Now, `$[0][*]` can be executed and returns all elements of the array, that is `{"class": "Station", "title": "Medina"}`
4. `$[0][*].class` returns the `class` field value: `"Station"`.

Arithmetic operations

> **Note**
>
> All arithmetic operations work with numbers as with Double. Calculations are made with potential loss of accuracy.

Unary operations

JsonPath supports unary `+` and `-`.

A unary operation applies to all values from the input sequence. If a unary operation's input is a value that isn't a number, a query fails in both modes.

Example

```
[1, 2, 3, 4]
```

The `strict -$[*]` query is successful and returns `-1, -2, -3, -4`.

The `lax -$` query fails as `$` is an array and not a number.

Binary operations

JsonPath supports binary arithmetic operations (in descending order of priority):

1. Multiplication `*`, dividing floating-point numbers `/`, and taking the remainder `%` (works as the `MOD` function in `SQL`).
2. Addition `+`, subtraction `-`.

You can change the order of operations using parentheses.

If each argument of a binary operation is not a single number or a number is divided by 0, the query fails in both modes.

Examples

- `(1 + 2) * 3` returns `9`
- `1 / 2` returns `0.5`
- `5 % 2` returns `1`
- `1 / 0` fails
- If JSON is `[-32.4, 5.2]`, the `$[0] % $[1]` query returns `-1.2`
- If JSON is `[1, 2, 3, 4]`, the `lax $[*] + $[*]` query fails as the `$[*]` expression execution result is `1, 2, 3, 4`, that is multiple numbers. A binary operation only requires one number for each of its arguments.

Boolean values

Unlike some other programming languages, Boolean values in JsonPath are not only `true` and `false`, but also `null` (uncertainty).

JsonPath considers any values received from a JSON document to be non-Boolean. For example, a query like `! $.is_valid_user` (a logical negation applied to the `is_valid_user`) field is syntactically invalid because the `is_valid_user` field value is not Boolean (even when it actually stores `true` or `false`). The correct way to write this kind of query is to explicitly use a comparison with a Boolean value, such as `$.is_valid_user == false`.

Logical operations

JsonPath supports some logical operations for Boolean values.

The arguments of any logical operation must be a single Boolean value.
All logical operations return a Boolean value.

Logical negation, !

Truth table:

`x`	`!x`
`true`	`false`
`false`	`true`
`Null`	`Null`

Logical AND, &&

In the truth table, the first column is the left argument, the first row is the right argument, and each cell is the result of using the Logical AND both with the left and right arguments:

`&&`	`true`	`false`	`Null`
`true`	`true`	`false`	`Null`
`false`	`false`	`false`	`false`
`Null`	`Null`	`false`	`Null`

Logical OR, ||

In the truth table, the first column is the left argument, the first row is the right argument, and each cell is the result of using the logical OR with both the left and right arguments:

`||`	`true`	`false`	`Null`
`true`	`true`	`true`	`true`
`false`	`true`	`false`	`Null`
`Null`	`true`	`Null`	`Null`

Examples

- `! (true == true)`, the result is `false`

- `(true == true) && (true == false)`, the result is `false`
- `(true == true) || (true == false)`, the result is `true`

Comparison operators

JsonPath implements comparison operators for values:

- Equality, `==`
- Inequality, `!=` and `<>`
- Less than and less than or equal to, `<` and `=`
- Greater than and greater than or equal to, `>` and `>=`

All comparison operators return a Boolean value. Both operator arguments support multiple values.

If an error occurs when calculating the operator arguments, it returns `null`. In this case, the JsonPath query execution continues.

The arrays of each of the arguments are automatically unpacked. After that, for each pair where the first element is taken from the sequence of the left argument and the second one from the sequence of the right argument:

1. The elements of the pair are compared
2. If an error occurs during the comparison, the `ERROR` flag is set.
3. If the comparison result is true, the flag set is `FOUND`
4. If either the `ERROR` or `FOUND` flag is set and the query is executed in `lax` mode, no more pairs are analyzed.

If the pair analysis results in:

1. The `ERROR` flag is set, the operator returns `null`
2. The `FOUND` flag is set, the operator returns `true`
3. Otherwise, it returns `false`

We can say that this algorithm considers all pairs from the Cartesian product of the left and right arguments, trying to find the pair whose comparison returns true.

Elements in a pair are compared according to the following rules:

1. If the left or right argument is an array or object, the comparison fails.
2. `null == null` returns true
3. In all other cases, if one of the arguments is `null`, false is returned.
4. If the left and right arguments are of different types, the comparison fails.
5. Strings are compared byte by byte.
6. `true` is considered greater than `false`
7. Numbers are compared with the accuracy of `1e-20`

Example

Let's take a JSON document as an example

```
{
    "left": [1, 2],
    "right": [4, "Inaros"]
}
```

and analyze the steps for executing the `lax $.left < $.right` query:

1. Auto unpacking of arrays in the left and right arguments. As a result, the left argument is the sequence `1, 2` and the right argument is `4, "Iranos"`
2. Let's take the pair `(1, 4)`. The comparison is successful as `1 < 4` is true. Set the flag `FOUND`
3. Since the query is executed in `lax` mode and the `FOUND` flag is set, we aren't analyzing any more pairs.
4. Since we have the `FOUND` flag set, the operator returns true.

Let's take the same query in a different execution mode: `strict $.left < $.right`:

1. Auto unpacking of arrays in the left and right arguments. As a result, the left argument is the sequence `1, 2` and the right argument is `4, "Iranos"`
2. Let's take the pair `(1, 4)`. The comparison is successful as `1 < 4` is true. Set the flag `FOUND`
3. Let's take the pair `(2, 4)`. The comparison is successful as `2 < 4` is true. Set the flag `FOUND`
4. Let's take the pair `(1, "Iranos")`. The comparison fails as a number can't be compared with a string. Set the flag `ERROR`
5. Let's take the pair `(2, "Iranos")`. The comparison fails as a number can't be compared with a string. Set the flag `ERROR`
6. Since we have the `ERROR` flag set, the operator returns `null`

Predicates

JsonPath supports predicates which are expressions that return a Boolean value and check a certain condition. You can use them, for example, in filters.

`like_regex`

The `like_regex` predicate lets you check if a string matches a regular expression. The syntax of regular expressions is the same as in Hyperscan UDF and REGEXP.

Syntax

```
<expression> like_regex <regexp string> [flag <flag string>]
```

Where:

1. `<expression>` is a JsonPath expression with strings to be checked for matching the regular expression.
2. `<regexp string>` is a string with the regular expression.
3. `flag <flag string>` is an optional section where `<flag string>` is a string with regular expression execution flags.

Supported flags:

- `i` : Disable the case sensitivity.

Execution

Before the check, the input sequence arrays are automatically unpacked.

After that, for each element of the input sequence:

1. A check is made to find out if a string matches a regular expression.
2. If the element isn't a string, the `ERROR` flag is set.
3. If the check result is true, the `FOUND` flag is set.
4. If either the `ERROR` or `FOUND` flag is set and the query is executed in `lax` mode, no more pairs are analyzed.

If the pair analysis results in:

1. Setting the `ERROR` flag, the predicate returns `null`
2. Setting the `FOUND` flag, the predicate returns `true`
3. Otherwise, the predicate returns `false`

Examples

1. `"123456" like_regex "^[0-9]+$"` returns `true`
2. `"123abcd456" like_regex "^[0-9]+$"` returns `false`
3. `"Naomi Nagata" like_regex "nag"` returns `false`
4. `"Naomi Nagata" like_regex "nag" flag "i"` returns `true`

`starts with`

The `starts with` predicate lets you check if one string is a prefix of another.

Syntax

```
<string expression> starts with <prefix expression>
```

Where:

1. `<string expression>` is a JsonPath expression with the string to check.
2. `<prefix expression>` is a JsonPath expression with a prefix string.

This means that the predicate will check that the `<string expression>` starts with the `<prefix expression>` string.

Execution

The first argument of the predicate must be a single string.

The second argument of the predicate must be a sequence of (possibly, multiple) strings.

For each element in a sequence of prefix strings:

1. A check is made for whether "an element is a prefix of an input string"
2. If the element isn't a string, the `ERROR` flag is set.
3. If the check result is true, the `FOUND` flag is set.
4. If either the `ERROR` or `FOUND` flag is set and the query is executed in `lax` mode, no more pairs are analyzed.

If the pair analysis results in:

1. Setting the `ERROR` flag, the predicate returns `null`
2. Setting the `FOUND` flag, the predicate returns `true`
3. Otherwise, the predicate returns `false`

Examples

1. `"James Holden" starts with "James"` returns `true`
2. `"James Holden" starts with "Amos"` returns `false`

`exists`

The `exists` predicate lets you check whether a JsonPath expression returns at least one element.

Syntax

```
exists (<expression>)
```

Where `<expression>` is the JsonPath expression to be checked. Parentheses around the expression are required.

Execution

1. The passed JsonPath expression is executed
2. If an error occurs, the predicate returns `null`
3. If an empty sequence is obtained as a result of the execution, the predicate returns `false`
4. Otherwise, the predicate returns `true`

Examples

Let's take a JSON document:

```
{
    "profile": {
        "name": "Josephus",
        "surname": "Miller"
    }
}
```

1. `exists ($.profile.name)` returns `true`
2. `exists ($.friends.profile.name)` returns `false`
3. `strict exists ($.friends.profile.name)` returns `null`, because accessing non-existent object keys in `strict` mode is an error.

`is unknown`

The `is unknown` predicate lets you check if a Boolean value is `null`.

Syntax

```
(<expression>) is unknown
```

Where `<expression>` is the JsonPath expression to be checked. Only expressions that return a Boolean value are allowed. Parentheses around the expression are required.

Execution

1. If the passed expression returns `null`, the predicate returns `true`
2. Otherwise, the predicate returns `false`

Examples

1. `(1 == 2) is unknown` returns `false`. The `1 == 2` expression returned `false`, which is not `null`
2. `(1 == "string") is unknown` returns `true`. The `1 == "string"` expression returned `null`, because strings and numbers can't be compared in JsonPath.

Filters

JsonPath lets you filter values obtained during query execution.

An expression in a filter must return a Boolean value.
Before filtering, the input sequence arrays are automatically unpacked.

For each element of the input sequence:

1. The value of the current filtered `@` object becomes equal to the current element of the input sequence.
2. Executing the expression in the filter
3. If an error occurs during the expression execution, the current element of the input sequence is skipped.
4. If the expression execution result is the only `true` value, the current element is added to the filter result.

Example

Suppose we have a JSON document describing the user's friends

```
{
    "friends": [
        {
            "name": "James Holden",
            "age": 35,
            "money": 500
        },
        {
            "name": "Naomi Nagata",
            "age": 30,
            "money": 345
        }
    ]
}
```

and we want to get a list of friends who are over 32 years old using a JsonPath query. To do this, you can write the following query:

```
$.friends ? (@.age > 32)
```

Let's analyze the query in parts:

- `$.friends` accesses the `friends` array in the JSON document.
- `? ( ... )` is the filter syntax. An expression inside the parentheses is called a predicate.
- `` accesses the currently filtered object. In our example, it's the object describing a friend of the user.
- `.age` accesses the `age` field of the currently filtered object.
- `.age > 32` compares the `age` field with the value 32. As a result of the query, only the values for which this predicate returned true remain.

The query only returns the first friend from the array of user's friends.

Like many other JsonPath operators, filters can be arranged in chains. Let's take a more complex query that selects the names of friends who are older than 20 and have less than 400 currency units:

```
$.friends ? (@.age > 20) ? (@.money < 400) . name
```

Let's analyze the query in parts:

- `$.friends` accesses the `friends` array in the JSON document.
- `? (@.age > 20)` is the first filter. Since all friends are over 20, it just returns all the elements of the `friends` array.
- `? (@.money < 400)` is the second filter. It only returns the second element of the `friends` array, since only its `money` field value is less than 400.
- `.name` accesses the `name` field of filtered objects.

The query returns a sequence of a single element: `"Naomi Nagata"`.

In practice, it's recommended to combine multiple filters into one if possible. The above query is equivalent to `$.friends ? (@.age > 20 && @.money < 400) . name`.

Methods

JsonPath supports methods that are functions converting one sequence of values to another. The syntax for calling a method is similar to accessing the object key:

```
$.friends.size()
```

Just like in the case of accessing object keys, method calls can be arranged in chains:

```
$.numbers.double().floor()
```

`type`

The `type` method returns a string with the type of the passed value.

For each element of the input sequence, the method adds this string to the output sequence according to the table below:

Value type	String with type
Null	`"null"`
Boolean value	`"boolean"`
Number	`"number"`
String	`"string"`
Array	`"array"`
Object	`"object"`

Examples

1. `"Naomi".type()` returns `"string"`
2. `false.type()` returns `"boolean"`

`size`

The `size` method returns the size of the array.

For each element of the input sequence, the method adds the following to the output sequence:

1. The size of the array if the element type is an array.
2. For all other types (including objects), it adds `1`

Examples

Let's take a JSON document:

```
{
    "array": [1, 2, 3],
    "object": {
        "a": 1,
        "b": 2
    },
    "scalar": "string"
}
```

And queries to it:

1. `$.array.size()` returns `3`
2. `$.object.size()` returns `1`
3. `$.scalar.size()` returns `1`

`Double`

The `double` method converts strings to numbers.

Before its execution, the input sequence arrays are automatically unpacked.

All elements in the input sequence must be strings that contain decimal numbers. It's allowed to specify the fractional part and exponent.

Examples

1. `"125".double()` returns `125`
2. `"125.456".double()` returns `125.456`
3. `"125.456e-3".double()` returns `0.125456`

`ceiling`

The `ceiling` method rounds up a number.

Before its execution, the input sequence arrays are automatically unpacked.

All elements in the input sequence must be numbers.

Examples

1. `(1.3).ceiling()` returns `2`
2. `(1.8).ceiling()` returns `2`
3. `(1.5).ceiling()` returns `2`
4. `(1.0).ceiling()` returns `1`

`floor`

The `floor` method rounds down a number.

Before its execution, the input sequence arrays are automatically unpacked.

All elements in the input sequence must be numbers.

Examples

1. `(1.3).floor()` returns `1`
2. `(1.8).floor()` returns `1`
3. `(1.5).floor()` returns `1`
4. `(1.0).floor()` returns `1`

`abs`

The `abs` method calculates the absolute value of a number (removes the sign).

Before its execution, the input sequence arrays are automatically unpacked.

All elements in the input sequence must be numbers.

Examples

1. `(0.0).abs()` returns `0`
2. `(1.0).abs()` returns `1`
3. `(-1.0).abs()` returns `1`

`keyvalue`

The `keyvalue` method converts an object to a sequence of key-value pairs.

Before its execution, the input sequence arrays are automatically unpacked.

All elements in the input sequence must be objects.

For each element of the input sequence:

1. Each key-value pair in the element is analyzed.
2. For each key-value pair, an object is generated with the keys `name` and `value`.
3. `name` stores a string with the name of the key from the pair.
4. `value` stores the value from the pair.
5. All objects for this element are added to the output sequence.

Examples

Let's take a JSON document:

```
{
    "name": "Chrisjen",
    "surname": "Avasarala",
    "age": 70
}
```

The `$.keyvalue()` query returns the following sequence for it:

```
{
    "name": "age",
    "value": 70
},
{
    "name": "name",
    "value": "Chrisjen"
},
{
    "name": "surname",
    "value": "Avasarala"
}
```

Variables

Functions using JsonPath can pass values into a query. They are called variables. To access a variable, write the `$` character and the variable name: `$variable`.

Example

Let the `planet` variable be equal to

```
{
    "name": "Mars",
    "gravity": 0.376
}
```

Then the `strict $planet.name` query returns `"Mars"`.

Unlike many programming languages, JsonPath doesn't support creating new variables or modifying existing ones.

Common arguments

All functions for JSON accept:

1. A JSON value (can be an arbitrary `Json` or `Json?` expression)
2. A JsonPath query (must be explicitly specified with a string literal)
3. **(Optional)** `PASSING` section

PASSING section

Lets you pass values to a JsonPath query as variables.

Syntax

```
PASSING
    <expression 1> AS <variable name 1>,
    <expression 2> AS <variable name 2>,
    ...
```

`<expression>` can have the following types:

- Numbers, `Date`, `DateTime`, and `Timestamp` (a `CAST` into `Double` will be made before passing a value to JsonPath)
- `Utf8`, `Bool`, and `Json`

You can set a `<variable name>` in several ways:

- As an SQL name like `variable`
- In quotes, for example, `"variable"`

Example

```
JSON_VALUE(
    $json,
    "$.timestamp - $Now + $Hour"
    PASSING
        24 * 60 as Hour,
        CurrentUtcTimestamp() as "Now"
)
```

JSON_EXISTS

The `JSON_EXISTS` function checks if a JSON value meets the specified JsonPath.

Syntax

```
JSON_EXISTS(
    <JSON expression>,
    <JsonPath query>,
    [<PASSING clause>]
    [{TRUE | FALSE | UNKNOWN | ERROR} ON ERROR]
)
```

Return value: `Bool?`

Default value: If the `ON ERROR` section isn't specified, the used section is `FALSE ON ERROR`

Behavior

1. If `<JSON expression>` is `NULL` or an empty `Json?`, it returns an empty `Bool?`
2. If an error occurs during JsonPath execution, the returned value depends on the `ON ERROR` section:
   - `TRUE`: Return `True`
   - `FALSE`: Return `False`
   - `UNKNOWN`: Return an empty `Bool?`
   - `ERROR`: Abort the entire query
3. If the result of JsonPath execution is one or more values, the return value is `True`.
4. Otherwise, `False` is returned.

Examples

```
$json = CAST(@@{
    "title": "Rocinante",
    "crew": [
        "James Holden",
        "Naomi Nagata",
        "Alex Kamai",
        "Amos Burton"
    ]
}@@ as Json);

SELECT
    JSON_EXISTS($json, "$.title"), -- True
    JSON_EXISTS($json, "$.crew[*]"), -- True
    JSON_EXISTS($json, "$.nonexistent"); -- False, as JsonPath returns an empty result

SELECT
    -- JsonPath error, False is returned because the default section used is FALSE ON ERROR
    JSON_EXISTS($json, "strict $.nonexistent");

SELECT
    -- JsonPath error, the entire YQL query fails.
    JSON_EXISTS($json, "strict $.nonexistent" ERROR ON ERROR);
```

JSON_VALUE

The `JSON_VALUE` function retrieves a scalar value from JSON (anything that isn't an array or object).

Syntax

```
JSON_VALUE(
    <JSON expression>,
    <JsonPath query>,
    [<PASSING clause>]
    [RETURNING <type>]
    [{ERROR | NULL | DEFAULT <expr>} ON EMPTY]
    [{ERROR | NULL | DEFAULT <expr>} ON ERROR]
)
```

Return value: `<type>?`

Default values:

1. If the `ON EMPTY` section isn't specified, the section used is `NULL ON EMPTY`
2. If the `ON ERROR` section isn't specified, the section used is `NULL ON ERROR`
3. If the `RETURNING` section isn't specified, then for `<type>`, the type used is `Utf8`

Behavior:

1. If `<JSON expression>` is `NULL` or an empty `Json?`, it returns an empty `<type>?`
2. If an error occurs, the returned value depends on the `ON ERROR` section:
   - `NULL`: Return an empty `<type>?`
   - `ERROR`: Abort the entire query
   - `DEFAULT <expr>`: Return `<expr>` after running the `CAST` function to convert the data type to `<type>?`. If the `CAST` fails, the entire query fails, too.
3. If the JsonPath execution result is empty, the returned value depends on the `ON EMPTY` section:
   - `NULL`: Return an empty `<type>?`
   - `ERROR`: Abort the entire query
   - `DEFAULT <expr>`: Return `<expr>` after running the `CAST` function to convert the data type to `<type>?`. If the `CAST` fails, the behavior matches the `ON ERROR` section.
4. If the result of JsonPath execution is a single value, then:
   - If the `RETURNING` section isn't specified, the value is converted to `Utf8`.
   - Otherwise, the `CAST` function is run to convert the value to `<type>`. If the `CAST` fails, the behavior matches the `ON ERROR` section. In this case, the value from JSON must match the `<type>` type.
5. Return the result

Correlation between JSON and YQL types:

- JSON Number: Numeric types, `Date`, `DateTime`, and `Timestamp`
- JSON Bool: `Bool`
- JSON String: `Utf8` and `String`

Errors executing `JSON_VALUE` are as follows:

- Errors evaluating JsonPath
- The result of JsonPath execution is a number of values or a non-scalar value.
- The type of value returned by JSON doesn't match the expected one.

`The RETURNING` section supports such types as numbers, `Date`, `DateTime`, `Timestamp`, `Utf8`, `String`, and `Bool`.

Examples

```
$json = CAST(@@{
    "friends": [
        {
            "name": "James Holden",
            "age": 35
        },
        {
            "name": "Naomi Nagata",
            "age": 30
        }
    ]
}@@ as Json);

SELECT
    JSON_VALUE($json, "$.friends[0].age"), -- "35" (type Utf8?)
    JSON_VALUE($json, "$.friends[0].age" RETURNING Uint64), -- 35 (type Uint64?)
    JSON_VALUE($json, "$.friends[0].age" RETURNING Utf8); -- an empty Utf8? due to an error. The JSON's Numbe
r type doesn't match the string Utf8 type.

SELECT
    -- "empty" (type String?)
    JSON_VALUE(
        $json,
        "$.friends[50].name"
        RETURNING String
        DEFAULT "empty" ON EMPTY
    );

SELECT
    -- 20 (type Uint64?). The result of JsonPath execution is empty, but the
    -- default value from the ON EMPTY section can't be cast to Uint64.
    -- That's why the value from ON ERROR is used.
    JSON_VALUE(
        $json,
        "$.friends[50].age"
        RETURNING Uint64
        DEFAULT -1 ON EMPTY
        DEFAULT 20 ON ERROR
    );
```

JSON_QUERY

The `JSON_QUERY` function lets you retrieve arrays and objects from JSON.

Syntax

```
JSON_QUERY(
    <JSON expression>,
    <JsonPath query>,
    [<PASSING clause>]
    [WITHOUT [ARRAY] | WITH [CONDITIONAL | UNCONDITIONAL] [ARRAY] WRAPPER]
    [{ERROR | NULL | EMPTY ARRAY | EMPTY OBJECT} ON EMPTY]
    [{ERROR | NULL | EMPTY ARRAY | EMPTY OBJECT} ON ERROR]
)
```

Return value: `Json?`

Default values:

1. If the `ON EMPTY` section isn't specified, the section used is `NULL ON EMPTY`
2. If the `ON ERROR` section isn't specified, the section used is `NULL ON ERROR`
3. If the `WRAPPER` section isn't specified, the section used is `WITHOUT WRAPPER`
4. If the `WITH WRAPPER` section is specified but `CONDITIONAL` or `UNCONDITIONAL` is omitted, then the section used is `UNCONDITIONAL`

Behavior:

> **Note**
>
> You can't specify the `WITH ... WRAPPER` and `ON EMPTY` sections at the same time.

1. If `<JSON expression>` is `NULL` or an empty `Json?`, it returns an empty `Json?`
2. If the `WRAPPER` section is specified, then:
   - `WITHOUT WRAPPER` or `WITHOUT ARRAY WRAPPER`: Don't convert the result of JsonPath execution in any way.
   - `WITH UNCONDITIONAL WRAPPER` or `WITH UNCONDITIONAL ARRAY WRAPPER`: Wrap the result of JsonPath execution in an array.

- `WITH CONDITIONAL WRAPPER` or `WITH CONDITIONAL ARRAY WRAPPER`: Wrap the result of JsonPath execution in an array if it isn't the only array or object.

3. If the JsonPath execution result is empty, the returned value depends on the `ON EMPTY` section:
   - `NULL`: Return an empty `Json?`
   - `ERROR`: Abort the entire query
   - `EMPTY ARRAY`: Return an empty JSON array, `[]`
   - `EMPTY OBJECT`: Return an empty JSON object, `{}`
4. If an error occurs, the returned value depends on the `ON ERROR` section:
   - `NULL`: Return an empty `Json?`
   - `ERROR`: Abort the entire query
   - `EMPTY ARRAY`: Return an empty JSON array, `[]`
   - `EMPTY OBJECT`: Return an empty JSON object, `{}`
5. Return the result

Errors running a `JSON_QUERY`:

- Errors evaluating JsonPath
- The result of JsonPath execution is a number of values (even after using the `WRAPPER` section) or a scalar value.

Examples

```
$json = CAST(@@{
    "friends": [
        {
            "name": "James Holden",
            "age": 35
        },
        {
            "name": "Naomi Nagata",
            "age": 30
        }
    ]
}@@ as Json);

SELECT
    JSON_QUERY($json, "$.friends[0]"); -- {"name": "James Holden", "age": 35}

SELECT
    JSON_QUERY($json, "$.friends.name" WITH UNCONDITIONAL WRAPPER); -- ["James Holden", "Naomi Nagata"]

SELECT
    JSON_QUERY($json, "$.friends[0]" WITH CONDITIONAL WRAPPER), -- {"name": "James Holden", "age": 35}
    JSON_QUERY($json, "$.friends.name" WITH CONDITIONAL WRAPPER); -- ["James Holden", "Naomi Nagata"]
```

- Roaring
- String
- Unicode
- Url
- Yson

DateTime

The DateTime module provides a set of functions for working with dates and times in YDB. These functions support all available timestamp and interval data types with both basic range of valid values and extended range. Additionally, these functions use their own internal representation of values, where each value is split into separate components. This representation is described below.

The simplest operations with timestamps and intervals can be performed without using the DateTime module. For example, conversion between strings and timestamps according to ISO 8601 is available through `CAST`, timestamp precision can also be changed using `CAST`, and arithmetic operators work between timestamps and intervals. The DateTime module is intended for tasks where these basic operations are insufficient and more complex transformations are required.

Internal representation format

Most functions in the DateTime module operate not on original timestamps and intervals, but on an internal representation based on a special resource data type. This represents a pointer to a data structure in memory where time components are stored separately. Working with resources happens exclusively through DateTime module functions. The typical workflow with this module (see examples at the end of the article) is as follows:

1. Call the `Split` function to get the internal representation from the original timestamp, or `Parse...` to get it from a string.
2. If necessary, call functions that modify this internal representation as needed, for example `Shift...`, `StartOf...` or `Update...`.
3. Call one of the functions to create a new value based on the internal representation, which can then be saved to tables or returned from a query:
   - `Make...` to create a new timestamp from the internal representation (not necessarily with the same precision as the original)
   - `Format` to get a string representation
   - `Get...` to get individual components

YDB supports two ranges of valid timestamp values: basic and extended. In the DateTime module, these correspond to two separate internal representations: `Resource<TM>` for basic data types and `Resource<TM64>` for data types with extended range of valid values.

`Resource<TM>` and `Resource<TM64>` contain the following date components:

- Year (for `Resource<TM>` 12 bits, unsigned; for `Resource<TM64>` 19 bits, signed)
- Month (4 bits)
- Day (5 bits)
- Hour (5 bits)
- Minute (6 bits)
- Second (6 bits)
- Microsecond (20 bits)
- TimezoneId (16 bits)
- DayOfYear (9 bits): Day since the beginning of the year
- WeekOfYear (6 bits): Week since the beginning of the year, January 1 is always in week 1
- WeekOfYearIso8601 (6 bits): Week of the year according to ISO 8601 (the first week is the one that includes January 4)
- DayOfWeek (3 bits): Day of the week

If the timezone is not GMT, the components store the local time for the relevant timezone.

Split

Conversion from a YDB primitive type to the internal representation of the DateTime module. Conversion is always successful when the required value is provided as input to the function.

List of functions

- `DateTime::Split(Date/TzDate/Datetime/TzDatetime/Timestamp/TzTimestamp{Flags:AutoMap}) -> Resource<TM>`
- `DateTime::Split(Date32/TzDate32/Datetime64/TzDatetime64/Timestamp64/TzTimestamp64{Flags:AutoMap}) -> Resource<TM64>`

Functions that accept `Resource<TM>` or `Resource<TM64>` as input can be called directly from the primitive date/time type. In this case, an implicit conversion will be made by calling the corresponding `Split` function.

Make...

Creating a YDB primitive type from the internal representation of the DateTime module. Conversion is always successful when the required value is provided as input to the function.

List of functions

- `DateTime::MakeDate(Resource<TM>{Flags:AutoMap}) -> Date`
- `DateTime::MakeDate32(Resource<TM64>{Flags:AutoMap}) -> Date32`
- `DateTime::MakeTzDate32(Resource<TM64>{Flags:AutoMap}) -> TzDate32`
- `DateTime::MakeDatetime(Resource<TM>{Flags:AutoMap}) -> Datetime`
- `DateTime::MakeTzDatetime(Resource<TM>{Flags:AutoMap}) -> TzDatetime`
- `DateTime::MakeDatetime64(Resource<TM64>{Flags:AutoMap}) -> Datetime64`
- `DateTime::MakeTzDatetime64(Resource<TM64>{Flags:AutoMap}) -> TzDatetime64`
- `DateTime::MakeTimestamp(Resource<TM>{Flags:AutoMap}) -> Timestamp`
- `DateTime::MakeTzTimestamp(Resource<TM>{Flags:AutoMap}) -> TzTimestamp`
- `DateTime::MakeTimestamp64(Resource<TM64>{Flags:AutoMap}) -> Timestamp64`
- `DateTime::MakeTzTimestamp64(Resource<TM64>{Flags:AutoMap}) -> TzTimestamp64`

Examples

```
SELECT
    DateTime::MakeTimestamp(DateTime::Split(Datetime("2019-01-01T15:30:00Z"))),
      -- 2019-01-01T15:30:00.000000Z
    DateTime::MakeDate(Datetime("2019-01-01T15:30:00Z")),
      -- 2019-01-01
    DateTime::MakeTimestamp(DateTime::Split(TzDatetime("2019-01-01T00:00:00,Europe/Moscow"))),
      -- 2018-12-31T21:00:00Z (conversion to UTC)
    DateTime::MakeDate(TzDatetime("2019-01-01T12:00:00,GMT"))
      -- 2019-01-01 (Datetime -> Date with implicit Split)
```

Get...

Extracting a component from the internal representation.

List of functions

- `DateTime::GetYear(Resource<TM>{Flags:AutoMap}) -> Uint16`
- `DateTime::GetYear(Resource<TM64>{Flags:AutoMap}) -> Int32`
- `DateTime::GetDayOfYear(Resource<TM>/Resource<TM64>{Flags:AutoMap}) -> Uint16`
- `DateTime::GetMonth(Resource<TM>/Resource<TM64>{Flags:AutoMap}) -> Uint8`
- `DateTime::GetMonthName(Resource<TM>/Resource<TM64>{Flags:AutoMap}) -> String`
- `DateTime::GetWeekOfYear(Resource<TM>/Resource<TM64>{Flags:AutoMap}) -> Uint8`
- `DateTime::GetWeekOfYearIso8601(Resource<TM>/Resource<TM64>{Flags:AutoMap}) -> Uint8`
- `DateTime::GetDayOfMonth(Resource<TM>/Resource<TM64>{Flags:AutoMap}) -> Uint8`
- `DateTime::GetDayOfWeek(Resource<TM>/Resource<TM64>{Flags:AutoMap}) -> Uint8`
- `DateTime::GetDayOfWeekName(Resource<TM>/Resource<TM64>{Flags:AutoMap}) -> String`
- `DateTime::GetHour(Resource<TM>/Resource<TM64>{Flags:AutoMap}) -> Uint8`
- `DateTime::GetMinute(Resource<TM>/Resource<TM64>{Flags:AutoMap}) -> Uint8`
- `DateTime::GetSecond(Resource<TM>/Resource<TM64>{Flags:AutoMap}) -> Uint8`
- `DateTime::GetMillisecondOfSecond(Resource<TM>/Resource<TM64>{Flags:AutoMap}) -> Uint32`
- `DateTime::GetMicrosecondOfSecond(Resource<TM>/Resource<TM64>{Flags:AutoMap}) -> Uint32`
- `DateTime::GetTimezoneId(Resource<TM>/Resource<TM64>{Flags:AutoMap}) -> Uint16`
- `DateTime::GetTimezoneName(Resource<TM>/Resource<TM64>{Flags:AutoMap}) -> String`

Examples

```
$tm = DateTime::Split(TzDatetime("2019-01-09T00:00:00,Europe/Moscow"));

SELECT
    DateTime::GetDayOfMonth($tm) as Day, -- 9
    DateTime::GetMonthName($tm) as Month, -- "January"
    DateTime::GetYear($tm) as Year, -- 2019
    DateTime::GetTimezoneName($tm) as TzName, -- "Europe/Moscow"
    DateTime::GetDayOfWeekName($tm) as WeekDay; -- "Wednesday"
```

Update

Updating one or more components in the internal representation. Returns either an updated copy or `NULL`, if an update produces an invalid date or other inconsistencies.

List of functions

```
DateTime::Update(Resource<TM>{Flags:AutoMap}, [ Year:Uint16?, Month:Uint8?, Day:Uint8?, Hour:Uint8?, Minute:U
int8?, Second:Uint8?, Microsecond:Uint32?, Timezone:String? ]) -> Resource<TM>?
DateTime::Update(Resource<TM64>{Flags:AutoMap}, [ Year:Int32?, Month:Uint8?, Day:Uint8?, Hour:Uint8?, Minute:
Uint8?, Second:Uint8?, Microsecond:Uint32?, Timezone:String? ]) -> Resource<TM64>?
```

Examples

```
$tm = DateTime::Split(Timestamp("2019-01-01T01:02:03.456789Z"));

SELECT
    DateTime::MakeDate(DateTime::Update($tm, 2012)), -- 2012-01-01
    DateTime::MakeDate(DateTime::Update($tm, 2000, 6, 6)), -- 2000-06-06
    DateTime::MakeDate(DateTime::Update($tm, NULL, 2, 30)), -- NULL (February 30)
    DateTime::MakeDatetime(DateTime::Update($tm, NULL, NULL, 31)), -- 2019-01-31T01:02:03Z
    DateTime::MakeDatetime(DateTime::Update($tm, 15 as Hour, 30 as Minute)), -- 2019-01-01T15:30:03Z
    DateTime::MakeTimestamp(DateTime::Update($tm, 999999 as Microsecond)), -- 2019-01-01T01:02:03.999999Z
    DateTime::MakeTimestamp(DateTime::Update($tm, "Europe/Moscow" as Timezone)), -- 2018-12-31T22:02:03.45678
9Z (conversion to UTC)
    DateTime::MakeTzTimestamp(DateTime::Update($tm, "Europe/Moscow" as Timezone)); -- 2019-01-01T01:02:03.456
789,Europe/Moscow
```

From...

Getting a Timestamp from the number of seconds/milliseconds/microseconds since the UTC epoch. When the Timestamp limits are exceeded, NULL is returned.

List of functions

- `DateTime::FromSeconds(Uint32{Flags:AutoMap}) -> Timestamp`
- `DateTime::FromSeconds64(Int64{Flags:AutoMap}) -> Timestamp64`
- `DateTime::FromMilliseconds(Uint64{Flags:AutoMap}) -> Timestamp`
- `DateTime::FromMilliseconds64(Int64{Flags:AutoMap}) -> Timestamp64`
- `DateTime::FromMicroseconds(Uint64{Flags:AutoMap}) -> Timestamp`
- `DateTime::FromMicroseconds64(Int64{Flags:AutoMap}) -> Timestamp64`

To...

Getting a number of seconds/milliseconds/microseconds since the UTC Epoch from a primitive type.

List of functions

- `DateTime::ToSeconds(Date/Datetime/Timestamp/TzDate/TzDatetime/TzTimestamp{Flags:AutoMap}) -> Uint32`
- `DateTime::ToSeconds(Date32/Datetime64/Timestamp64/TzDate32/TzDatetime64/TzTimestamp64{Flags:AutoMap}) -> Int64`
- `DateTime::ToMilliseconds(Date/Datetime/Timestamp/TzDate/TzDatetime/TzTimestamp{Flags:AutoMap}) -> Uint64`
- `DateTime::ToMilliseconds(Date32/Datetime64/Timestamp64/TzDate32/TzDatetime64/TzTimestamp64{Flags:AutoMap}) -> Int64`
- `DateTime::ToMicroseconds(Date/Datetime/Timestamp/TzDate/TzDatetime/TzTimestamp{Flags:AutoMap}) -> Uint64`
- `DateTime::ToMicroseconds(Date32/Datetime64/Timestamp64/TzDate32/TzDatetime64/TzTimestamp64{Flags:AutoMap}) -> Int64`

Examples

```
SELECT
    DateTime::FromSeconds(1546304523), -- 2019-01-01T01:02:03.000000Z
    DateTime::ToMicroseconds(Timestamp("2019-01-01T01:02:03.456789Z")); -- 1546304523456789
```

Interval...

Conversions between `Interval` and various time units.

List of functions

- `DateTime::ToDays(Interval{Flags:AutoMap}) -> Int32`
- `DateTime::ToDays(Interval64{Flags:AutoMap}) -> Int32`
- `DateTime::ToHours(Interval{Flags:AutoMap}) -> Int32`
- `DateTime::ToHours(Interval64{Flags:AutoMap}) -> Int64`
- `DateTime::ToMinutes(Interval{Flags:AutoMap}) -> Int32`
- `DateTime::ToMinutes(Interval64{Flags:AutoMap}) -> Int64`
- `DateTime::ToSeconds(Interval{Flags:AutoMap}) -> Int64`
- `DateTime::ToSeconds(Interval64{Flags:AutoMap}) -> Int64`
- `DateTime::ToMilliseconds(Interval{Flags:AutoMap}) -> Int64`
- `DateTime::ToMilliseconds(Interval64{Flags:AutoMap}) -> Int64`
- `DateTime::ToMicroseconds(Interval{Flags:AutoMap}) -> Int64`
- `DateTime::ToMicroseconds(Interval64{Flags:AutoMap}) -> Int64`
- `DateTime::IntervalFromDays(Int32{Flags:AutoMap}) -> Interval`
- `DateTime::Interval64FromDays(Int32{Flags:AutoMap}) -> Interval64`
- `DateTime::IntervalFromHours(Int32{Flags:AutoMap}) -> Interval`
- `DateTime::Interval64FromHours(Int64{Flags:AutoMap}) -> Interval64`
- `DateTime::IntervalFromMinutes(Int32{Flags:AutoMap}) -> Interval`
- `DateTime::Interval64FromMinutes(Int64{Flags:AutoMap}) -> Interval64`
- `DateTime::IntervalFromSeconds(Int64{Flags:AutoMap}) -> Interval`
- `DateTime::Interval64FromSeconds(Int64{Flags:AutoMap}) -> Interval64`
- `DateTime::IntervalFromMilliseconds(Int64{Flags:AutoMap}) -> Interval`
- `DateTime::Interval64FromMilliseconds(Int64{Flags:AutoMap}) -> Interval64`
- `DateTime::IntervalFromMicroseconds(Int64{Flags:AutoMap}) -> Interval`
- `DateTime::Interval64FromMicroseconds(Int64{Flags:AutoMap}) -> Interval64`

`AddTimezone` doesn't affect the output of `ToSeconds()` in any way, because `ToSeconds()` always returns GMT time.

Interval can also be created from a string literal in the format ISO 8601.

> **Warning**
>
> Currently, only literals for deterministic intervals are supported. All dimensions larger than a week — `M` (month) and `Y` (year) — are not fixed, since their duration is determined only by external context, the calendar.

Examples

```
SELECT
    DateTime::ToDays(Interval("PT3000M")), -- 2
    DateTime::IntervalFromSeconds(1000000), -- 11 days 13 hours 46 minutes 40 seconds
    DateTime::ToDays(CAST('2018-01-01' as date) - CAST('2017-12-31' as date)); --1
```

StartOf... / EndOf... / TimeOfDay

Get the start (end) of the period including the date/time. If the result is invalid, NULL is returned. If the timezone is different from GMT, then the period start (end) is in the specified time zone.

List of functions

- `DateTime::StartOfYear(Resource<TM>{Flags:AutoMap}) -> Resource<TM>?`
- `DateTime::StartOfYear(Resource<TM64>{Flags:AutoMap}) -> Resource<TM64>?`
- `DateTime::EndOfYear(Resource<TM>{Flags:AutoMap}) -> Resource<TM>?`
- `DateTime::EndOfYear(Resource<TM64>{Flags:AutoMap}) -> Resource<TM64>?`
- `DateTime::StartOfQuarter(Resource<TM>{Flags:AutoMap}) -> Resource<TM>?`
- `DateTime::StartOfQuarter(Resource<TM64>{Flags:AutoMap}) -> Resource<TM64>?`
- `DateTime::EndOfQuarter(Resource<TM>{Flags:AutoMap}) -> Resource<TM>?`
- `DateTime::EndOfQuarter(Resource<TM64>{Flags:AutoMap}) -> Resource<TM64>?`
- `DateTime::StartOfMonth(Resource<TM>{Flags:AutoMap}) -> Resource<TM>?`
- `DateTime::StartOfMonth(Resource<TM64>{Flags:AutoMap}) -> Resource<TM64>?`
- `DateTime::EndOfMonth(Resource<TM>{Flags:AutoMap}) -> Resource<TM>?`
- `DateTime::EndOfMonth(Resource<TM64>{Flags:AutoMap}) -> Resource<TM64>?`
- `DateTime::StartOfWeek(Resource<TM>{Flags:AutoMap}) -> Resource<TM>?`
- `DateTime::StartOfWeek(Resource<TM64>{Flags:AutoMap}) -> Resource<TM64>?`
- `DateTime::EndOfWeek(Resource<TM>{Flags:AutoMap}) -> Resource<TM>?`
- `DateTime::EndOfWeek(Resource<TM64>{Flags:AutoMap}) -> Resource<TM64>?`
- `DateTime::StartOfDay(Resource<TM>{Flags:AutoMap}) -> Resource<TM>?`
- `DateTime::StartOfDay(Resource<TM64>{Flags:AutoMap}) -> Resource<TM64>?`
- `DateTime::EndOfDay(Resource<TM>{Flags:AutoMap}) -> Resource<TM>?`
- `DateTime::EndOfDay(Resource<TM64>{Flags:AutoMap}) -> Resource<TM64>?`
- `DateTime::StartOf(Resource<TM>{Flags:AutoMap}, Interval{Flags:AutoMap}) -> Resource<TM>?`
- `DateTime::StartOf(Resource<TM64>{Flags:AutoMap}, Interval64{Flags:AutoMap}) -> Resource<TM64>?`
- `DateTime::EndOf(Resource<TM>{Flags:AutoMap}, Interval{Flags:AutoMap}) -> Resource<TM>?`
- `DateTime::EndOf(Resource<TM64>{Flags:AutoMap}, Interval64{Flags:AutoMap}) -> Resource<TM64>?`

The `StartOf` / `EndOf` functions are intended for grouping by an arbitrary period within a day. The result differs from the input value only by time components. A period exceeding one day is treated as a day (an equivalent of `StartOfDay` / `EndOfDay`). If a day doesn't include an integer number of periods, the number is rounded to the nearest time from the beginning of the day that is a multiple of the specified period. When the interval is zero, the output is same as the input. A negative interval is treated as a positive one.

The `EndOf...` functions are intended for obtaining the latest moment in the same period of time as the specified one.

The functions treat periods longer than one day in a different manner than the same-name functions in the old library. The time components are always reset to zero (this makes sense, because these functions are mainly used for grouping by the period). You can also specify a time period within a day:

- `DateTime::TimeOfDay(Resource<TM>{Flags:AutoMap}) -> Interval`
- `DateTime::TimeOfDay(Resource<TM64>{Flags:AutoMap}) -> Interval64`

Examples

```
SELECT
    DateTime::MakeDate(DateTime::StartOfYear(Date("2019-06-06"))),
      -- 2019-01-01 (implicit Split here and below)
    DateTime::MakeDatetime(DateTime::StartOfQuarter(Datetime("2019-06-06T01:02:03Z"))),
      -- 2019-04-01T00:00:00Z (time components are reset to zero)
    DateTime::MakeDate(DateTime::StartOfMonth(Timestamp("2019-06-06T01:02:03.456789Z"))),
      -- 2019-06-01
    DateTime::MakeDate(DateTime::StartOfWeek(Date("1970-01-01"))),
      -- NULL (the beginning of the epoch is Thursday, the beginning of the week is 1969-12-29 that is beyond
the limits)
    DateTime::MakeTimestamp(DateTime::StartOfWeek(Date("2019-01-01"))),
      -- 2018-12-31T00:00:00Z
    DateTime::MakeDatetime(DateTime::StartOfDay(Datetime("2019-06-06T01:02:03Z"))),
      -- 2019-06-06T00:00:00Z
    DateTime::MakeTzDatetime(DateTime::StartOfDay(TzDatetime("1970-01-01T05:00:00,Europe/Moscow"))),
      -- NULL (beyond the epoch in GMT)
    DateTime::MakeTzTimestamp(DateTime::StartOfDay(TzTimestamp("1970-01-02T05:00:00.000000,Europe/Moscow"))),
      -- 1970-01-02T00:00:00,Europe/Moscow (the beginning of the day in Moscow)
    DateTime::MakeDatetime(DateTime::StartOf(Datetime("2019-06-06T23:45:00Z"), Interval("PT7H"))),
      -- 2019-06-06T21:00:00Z
    DateTime::MakeDatetime(DateTime::StartOf(Datetime("2019-06-06T23:45:00Z"), Interval("PT20M"))),
      -- 2019-06-06T23:40:00Z
    DateTime::TimeOfDay(Timestamp("2019-02-14T01:02:03.456789Z"));
      -- 1 hour 2 minutes 3 seconds 456789 microseconds
```

Shift...

Add/subtract the specified number of units to/from the component in the internal representation and update the other fields. Returns either an updated copy or NULL, if an update produces an invalid date or other inconsistencies.

List of functions

- `DateTime::ShiftYears(Resource<TM>{Flags:AutoMap}, Int32) -> Resource<TM>?`
- `DateTime::ShiftYears(Resource<TM64>{Flags:AutoMap}, Int32) -> Resource<TM64>?`
- `DateTime::ShiftQuarters(Resource<TM>{Flags:AutoMap}, Int32) -> Resource<TM>?`
- `DateTime::ShiftQuarters(Resource<TM64>{Flags:AutoMap}, Int32) -> Resource<TM64>?`
- `DateTime::ShiftMonths(Resource<TM>{Flags:AutoMap}, Int32) -> Resource<TM>?`
- `DateTime::ShiftMonths(Resource<TM64>{Flags:AutoMap}, Int32) -> Resource<TM64>?`

If the resulting number of the day in the month exceeds the maximum allowed, then the `Day` field will accept the last day of the month without changing the time (see examples).

Examples

```
$tm1 = DateTime::Split(DateTime("2019-01-31T01:01:01Z"));
$tm2 = DateTime::Split(TzDatetime("2049-05-20T12:34:50,Europe/Moscow"));

SELECT
    DateTime::MakeDate(DateTime::ShiftYears($tm1, 10)), -- 2029-01-31T01:01:01
    DateTime::MakeDate(DateTime::ShiftYears($tm2, -10000)), -- NULL (beyond the limits)
    DateTime::MakeDate(DateTime::ShiftQuarters($tm2, 0)), -- 2049-05-20T12:34:50,Europe/Moscow
    DateTime::MakeDate(DateTime::ShiftQuarters($tm1, -3)), -- 2018-04-30T01:01:01
    DateTime::MakeDate(DateTime::ShiftMonths($tm1, 1)), -- 2019-02-28T01:01:01
    DateTime::MakeDate(DateTime::ShiftMonths($tm1, -35)), -- 2016-02-29T01:01:01
```

Format

Get a string representation of a time using an arbitrary formatting string.

List of functions

- `DateTime::Format(String, alwaysWriteFractionalSeconds:Bool?) -> (Resource<TM64>{Flags:AutoMap}) -> String`

A set of specifiers is implemented for the formatting string:

- `%%` : % character
- `%Y` : year, 1–6 digits and sign for BC dates
- `%m` : 2-digit month
- `%d` : 2-digit day
- `%H` : 2-digit hour
- `%M` : 2-digit minutes
- `%S` : 2-digit seconds or `XX.XXXXXX` in the case of non-empty microseconds (only if `alwaysWriteFractionalSeconds` is not set to `True`)
- `%z` : `+hhmm` or `-hhmm`
- `%Z` : IANA name of the timezone
- `%b` : A short three-letter English name of the month (Jan)
- `%B` : A full English name of the month (January)

All other characters in the format string are passed on without changes.

Examples

```
$format = DateTime::Format("%Y-%m-%d %H:%M:%S %Z");

SELECT
    $format(DateTime::Split(TzDatetime("2019-01-01T01:02:03,Europe/Moscow")));
      -- "2019-01-01 01:02:03 Europe/Moscow"
```

Parse/Parse64

Parse a string into an internal representation using an arbitrary formatting string. Default values are used for empty fields. If errors are raised, NULL is returned.

List of functions

- `DateTime::Parse(String) -> (String{Flags:AutoMap}) -> Resource<TM>?`
- `DateTime::Parse64(String) -> (String{Flags:AutoMap}) -> Resource<TM64>?`

Implemented specifiers:

- `%%` : the % character
- `%Y` : 4-digit year when using `Parse` , or 1–6 digits and sign for BC dates when using `Parse64`
- `%m` : 2-digit month
- `%d` : 2-digit day
- `%H` : 2-digit hour
- `%M` : 2-digit minutes
- `%S` : Seconds, can also accept microseconds in the formats from `XX` up to `XX.XXXXXX`
- `%Z` : The IANA name of the timezone (e.g., GMT)

- `%b`: A short three-letter case-insensitive English name of the month (e.g., Jan)
- `%B`: A full case-insensitive English name of the month (January)

Examples

```
$parse1 = DateTime::Parse("%H:%M:%S");
$parse2 = DateTime::Parse("%S");
$parse3 = DateTime::Parse("%m/%d/%Y");
$parse4 = DateTime::Parse("%Z");
$parse5 = DateTime::Parse64("%m/%d/%Y");

SELECT
    DateTime::MakeDatetime($parse1("01:02:03")), -- 1970-01-01T01:02:03Z
    DateTime::MakeTimestamp($parse2("12.3456")), -- 1970-01-01T00:00:12.345600Z
    DateTime::MakeTimestamp($parse3("02/30/2000")), -- NULL (Feb 30)
    DateTime::MakeTimestamp($parse4("Canada/Central")), -- 1970-01-01T06:00:00Z (conversion to UTC)
    DateTime::MakeTimestamp64($parse5("02/10/1931")); -- 1931-02-10T00:00:00Z (conversion to UTC)
```

Parse specific formats

For the common formats, wrappers around the corresponding util methods are supported. You can only get TM with components in the UTC timezone.

List of functions

- `DateTime::ParseRfc822(String{Flags:AutoMap}) -> Resource<TM>?`
- `DateTime::ParseIso8601(String{Flags:AutoMap}) -> Resource<TM>?`
- `DateTime::ParseHttp(String{Flags:AutoMap}) -> Resource<TM>?`
- `DateTime::ParseX509(String{Flags:AutoMap}) -> Resource<TM>?`

Examples

```
SELECT
    DateTime::MakeTimestamp(DateTime::ParseRfc822("Fri, 4 Mar 2005 19:34:45 EST")),
      -- 2005-03-05T00:34:45Z
    DateTime::MakeTimestamp(DateTime::ParseIso8601("2009-02-14T02:31:30+0300")),
      -- 2009-02-13T23:31:30Z
    DateTime::MakeTimestamp(DateTime::ParseHttp("Sunday, 06-Nov-94 08:49:37 GMT")),
      -- 1994-11-06T08:49:37Z
    DateTime::MakeTimestamp(DateTime::ParseX509("20091014165533Z"))
      -- 2009-10-14T16:55:33Z
```

Standard scenarios

Conversions between strings and seconds

Converting a string date (in the Moscow timezone) to seconds (in GMT timezone):

```
$datetime_parse = DateTime::Parse("%Y-%m-%d %H:%M:%S");
$datetime_parse_tz = DateTime::Parse("%Y-%m-%d %H:%M:%S %Z");

SELECT
    DateTime::ToSeconds(TzDatetime("2019-09-16T00:00:00,Europe/Moscow")) AS md_us1, -- 1568581200
    DateTime::ToSeconds(DateTime::MakeDatetime($datetime_parse_tz("2019-09-16 00:00:00" || " Europe/Mosco
w"))), -- 1568581200
    DateTime::ToSeconds(DateTime::MakeDatetime(DateTime::Update($datetime_parse("2019-09-16 00:00:00"), "Euro
pe/Moscow" AS Timezone))), -- 1568581200
    -- INCORRECT (Date imports time as GMT, but AddTimezone has no effect on ToSeconds that always returns GM
T time)
    DateTime::ToSeconds(AddTimezone(Date("2019-09-16"), 'Europe/Moscow')) AS md_us2, -- 1568592000
```

Converting a string date (in the Moscow timezone) to seconds (in the Moscow timezone). Since `DateTime::ToSeconds()` exports only GMT, we have to temporarily forget about timezones and work only in GMT (it looks like we temporarily assume that Moscow is in GMT timezone):

```
$date_parse = DateTime::Parse("%Y-%m-%d");
$datetime_parse = DateTime::Parse("%Y-%m-%d %H:%M:%S");
$datetime_parse_tz = DateTime::Parse("%Y-%m-%d %H:%M:%S %Z");

SELECT
    DateTime::ToSeconds(Datetime("2019-09-16T00:00:00Z")) AS md_ms1, -- 1568592000
    DateTime::ToSeconds(Date("2019-09-16")) AS md_ms2, -- 1568592000
    DateTime::ToSeconds(DateTime::MakeDatetime($date_parse("2019-09-16"))) AS md_ms3, -- 1568592000
    DateTime::ToSeconds(DateTime::MakeDatetime($datetime_parse("2019-09-16 00:00:00"))) AS md_ms4, -- 1568592
000
    DateTime::ToSeconds(DateTime::MakeDatetime($datetime_parse_tz("2019-09-16 00:00:00 GMT"))) AS md_ms5, --
1568592000

    -- INCORRECT (imports the time in the Moscow timezone, but RemoveTimezone doesn't affect ToSeconds in any
way)
    DateTime::ToSeconds(RemoveTimezone(TzDatetime("2019-09-16T00:00:00,Europe/Moscow"))) AS md_ms6, -- 156858
1200
    DateTime::ToSeconds(DateTime::MakeDatetime($datetime_parse_tz("2019-09-16 00:00:00 Europe/Moscow"))) AS m
d_ms7 -- 1568581200
```

Converting seconds (in the GMT timezone) to a string date (in the Moscow timezone):

```
$date_format = DateTime::Format("%Y-%m-%d %H:%M:%S %Z");
SELECT
    $date_format(AddTimezone(DateTime::FromSeconds(1568592000), 'Europe/Moscow')) -- "2019-09-16 03:00:00 Eur
ope/Moscow"
```

Converting seconds (in the Moscow timezone) to a string date (in the Moscow timezone). In this case, the `%Z` timezone is output for reference: usually, it's not needed because it's "GMT" and might mislead you.

```
$date_format = DateTime::Format("%Y-%m-%d %H:%M:%S %Z");
SELECT
    $date_format(DateTime::FromSeconds(1568592000)) -- "2019-09-16 00:00:00 GMT"
```

Converting seconds (in the GMT timezone) to three-letter days of the week (in the Moscow timezone):

```
SELECT
    SUBSTRING(DateTime::GetDayOfWeekName(AddTimezone(DateTime::FromSeconds(1568581200), "Europe/Moscow")), 0,
3) -- "Mon"
```

Date and time formatting

Usually a separate named expression is used to format time, but you can do without it:

```
$date_format = DateTime::Format("%Y-%m-%d %H:%M:%S %Z");

SELECT

   -- A variant with a named expression

   $date_format(AddTimezone(DateTime::FromSeconds(1568592000), 'Europe/Moscow')),

   -- A variant without a named expression

   DateTime::Format("%Y-%m-%d %H:%M:%S %Z")
       (AddTimezone(DateTime::FromSeconds(1568592000), 'Europe/Moscow'))
;
```

Converting types

This way, you can convert only constants:

```
SELECT
    TzDatetime("2019-09-16T00:00:00,Europe/Moscow"), -- 2019-09-16T00:00:00,Europe/Moscow
    Date("2019-09-16") -- 2019-09-16
```

But this way, you can convert a constant, a named expression, or a table field:

```
SELECT
CAST("2019-09-16T00:00:00,Europe/Moscow" AS TzDatetime), -- 2019-09-16T00:00:00,Europe/Moscow
    CAST("2019-09-16" AS Date) -- 2019-09-16
```

Converting time to date

A `CAST` to `Date` or `TzDate` outputs a GMT date for a midnight, local time (for example, for Moscow time 2019-10-22 00:00:00, the date 2019-10-21 is returned). To get a date in the local timezone, you can use DateTime::Format.

```
$x = Datetime("2019-10-21T21:00:00Z");
SELECT
    AddTimezone($x, "Europe/Moscow"), -- 2019-10-22T00:00:00,Europe/Moscow
    CAST($x as TzDate), -- 2019-10-21,GMT
    CAST(AddTimezone($x, "Europe/Moscow") as TzDate), -- 2019-10-21,Europe/Moscow
    CAST(AddTimezone($x, "Europe/Moscow") as Date), -- 2019-10-21
  DateTime::Format("%Y-%m-%d %Z")(AddTimezone($x, "Europe/Moscow")), -- 2019-10-22 Europe/Moscow
```

It's worth mentioning that several `TzDatetime` or `TzTimestamp` values with a positive timezone offset cannot be cast to `TzDate`. Consider the example below:

```
SELECT CAST(TzDatetime("1970-01-01T23:59:59,Europe/Moscow") as TzDate);
/* Fatal: Timestamp 1970-01-01T23:59:59.000000,Europe/Moscow cannot be casted to TzDate */
```

There is no valid value, starting from the Unix epoch, that can represent midnight on 01/01/1970 for the Moscow timezone. As a result, such a cast is considered impossible and generates a runtime error.

However, values with a negative timezone offset return a correct result:

```
SELECT CAST(TzDatetime("1970-01-01T23:59:59,America/Los_Angeles") as TzDate);
/* 1970-01-01,America/Los_Angeles */
```

Daylight saving time

Note that daylight saving time depends on the year:

```
SELECT
    RemoveTimezone(TzDatetime("2019-09-16T10:00:00,Europe/Moscow")) as DST1, -- 2019-09-16T07:00:00Z
    RemoveTimezone(TzDatetime("2008-12-03T10:00:00,Europe/Moscow")) as DST2, -- 2008-12-03T07:00:00Z
    RemoveTimezone(TzDatetime("2008-07-03T10:00:00,Europe/Moscow")) as DST3, -- 2008-07-03T06:00:00Z (DST)
```

Digest

A set of commonly used hash functions.

List of functions

- `Digest::Crc32c(String{Flags::AutoMap}) -> Uint32`
- `Digest::Crc64(String{Flags::AutoMap}, [Init:Uint64?]) -> Uint64`
- `Digest::Fnv32(String{Flags::AutoMap}, [Init:Uint32?]) -> Uint32`
- `Digest::Fnv64(String{Flags::AutoMap}, [Init:Uint64?]) -> Uint64`
- `Digest::MurMurHash(String{Flags:AutoMap}, [Init:Uint64?]) -> Uint64`
- `Digest::MurMurHash32(String{Flags:AutoMap}, [Init:Uint32?]) -> Uint32`
- `Digest::MurMurHash2A(String{Flags:AutoMap}, [Init:Uint64?]) -> Uint64`
- `Digest::MurMurHash2A32(String{Flags:AutoMap}, [Init:Uint32?]) -> Uint32`
- `Digest::CityHash(String{Flags:AutoMap}, [Init:Uint64?]) -> Uint64`
- `Digest::CityHash128(String{Flags:AutoMap}) -> Tuple<Uint64,Uint64>`
- `Digest::NumericHash(Uint64{Flags:AutoMap}) -> Uint64`
- `Digest::Md5Hex(String{Flags:AutoMap}) -> String`
- `Digest::Md5Raw(String{Flags:AutoMap}) -> String`
- `Digest::Md5HalfMix(String{Flags:AutoMap}) -> Uint64`: MD5 coarsening option (yabs_md5)
- `Digest::Argon2(String{Flags:AutoMap},String{Flags:AutoMap}) -> String`: The second argument is the salt
- `Digest::Blake2B(String{Flags:AutoMap},[String?]) -> String`: The second optional argument is the key
- `Digest::SipHash(Uint64,Uint64,String{Flags:AutoMap}) -> Uint64`
- `Digest::HighwayHash(Uint64,Uint64,Uint64,Uint64,String{Flags:AutoMap}) -> Uint64`
- `Digest::FarmHashFingerprint(Uint64{Flags:AutoMap}) -> Uint64`
- `Digest::FarmHashFingerprint2(Uint64{Flags:AutoMap}, Uint64{Flags:AutoMap}) -> Uint64`
- `Digest::FarmHashFingerprint32(String{Flags:AutoMap}) -> Uint32`
- `Digest::FarmHashFingerprint64(String{Flags:AutoMap}) -> Uint64`
- `Digest::FarmHashFingerprint128(String{Flags:AutoMap}) -> Tuple<Uint64,Uint64>`
- `Digest::SuperFastHash(String{Flags:AutoMap}) -> Uint32`
- `Digest::Sha1(String{Flags:AutoMap}) -> String`
- `Digest::Sha256(String{Flags:AutoMap}) -> String`
- `Digest::IntHash64(Uint64{Flags:AutoMap}) -> Uint64`
- `Digest::XXH3(String{Flags:AutoMap}) -> Uint64`
- `Digest::XXH3_128(String{Flags:AutoMap}) -> Tuple<Uint64,Uint64>`

The functions for the hashes that support the initialization parameter (seed) accept its value in the optional named argument `Init`.

Examples

```
SELECT Digest::Md5Hex("YQL");  -- "1a0c1b56e9d617688ee345da4030da3c"
SELECT Digest::NumericHash(123456789); -- 1734215268924325803
```

Histogram

Set of auxiliary functions for the HISTOGRAM aggregate function. In the signature description below, HistogramStruct refers to the result of the aggregate function `HISTOGRAM`, `LinearHistogram` or `LogarithmicHistogram` being a structure of a certain type.

List of functions

- `Histogram::Print(HistogramStruct{Flags:AutoMap}, Byte?) -> String`
- `Histogram::Normalize(HistogramStruct{Flags:AutoMap}, [Double?]) -> HistogramStruct`: The second argument specifies the desired area of the histogram, 100 by default.
- `Histogram::ToCumulativeDistributionFunction(HistogramStruct{Flags:AutoMap}) -> HistogramStruct`
- `Histogram::GetSumAboveBound(HistogramStruct{Flags:AutoMap}, Double) -> Double`
- `Histogram::GetSumBelowBound(HistogramStruct{Flags:AutoMap}, Double) -> Double`
- `Histogram::GetSumInRange(HistogramStruct{Flags:AutoMap}, Double, Double) -> Double`
- `Histogram::CalcUpperBound(HistogramStruct{Flags:AutoMap}, Double) -> Double`
- `Histogram::CalcLowerBound(HistogramStruct{Flags:AutoMap}, Double) -> Double`
- `Histogram::CalcUpperBoundSafe(HistogramStruct{Flags:AutoMap}, Double) -> Double`
- `Histogram::CalcLowerBoundSafe(HistogramStruct{Flags:AutoMap}, Double) -> Double`

`Histogram::Print` has an optional numeric argument that sets the maximum length of the histogram columns (the length is in characters, since the histogram is rendered in ASCII art). Default: 25. This function is primarily intended for viewing histograms in the console.

Hyperscan

Hyperscan is an opensource library for regular expression matching developed by Intel.

The library includes 4 implementations that use different sets of processor instructions (SSE3, SSE4.2, AVX2, and AVX512), with the needed instruction automatically selected based on the current processor.

By default, all functions work in the single-byte mode. However, if the regular expression is a valid UTF-8 string but is not a valid ASCII string, the UTF-8 mode is enabled automatically.

List of functions

- `Hyperscan::Grep(pattern:String) -> (string:String?) -> Bool`
- `Hyperscan::Match(pattern:String) -> (string:String?) -> Bool`
- `Hyperscan::BacktrackingGrep(pattern:String) -> (string:String?) -> Bool`
- `Hyperscan::BacktrackingMatch(pattern:String) -> (string:String?) -> Bool`
- `Hyperscan::MultiGrep(pattern:String) -> (string:String?) -> Tuple<Bool, Bool, ...>`
- `Hyperscan::MultiMatch(pattern:String) -> (string:String?) -> Tuple<Bool, Bool, ...>`
- `Hyperscan::Capture(pattern:String) -> (string:String?) -> String?`
- `Hyperscan::Replace(pattern:String) -> (string:String?, replacement:String) -> String?`

Call syntax

To avoid compiling a regular expression at each table row at direct call, wrap the function call by a named expression:

```
$re = Hyperscan::Grep("\\d+");      -- create a callable value to match a specific regular expression
SELECT * FROM table WHERE $re(key); -- use it to filter the table
```

Note

Please note escaping of special characters in regular expressions. Be sure to use the second slash, since all the standard string literals in SQL can accept C-escaped strings, and the `\d` sequence is not valid sequence (even if it were, it wouldn't search for numbers as intended).

You can enable the case-insensitive mode by specifying, at the beginning of the regular expression, the flag `(?i)`.

Grep

Matches the regular expression with a **part of the string** (arbitrary substring).

Match

Matches **the whole string** against the regular expression.

To get a result similar to `Grep` (where substring matching is included), enclose the regular expression in `.*` (`.*foo.*` instead of `foo`). However, in terms of code readability, it's usually better to change the function.

BacktrackingGrep/BacktrackingMatch

The functions are identical to the same-name functions without the `Backtracking` prefix. However, they support a broader range of regular expressions. This is due to the fact that if a specific regular expression is not fully supported by Hyperscan, the library switches to the prefilter mode. In this case, it responds not by "Yes" or "No", but by "Definitely not" or "Maybe yes". The "Maybe yes" responses are then automatically rechecked using a slower, but more functional, library libpcre.

MultiGrep/MultiMatch

Hyperscan lets you match against multiple regular expressions in a single pass through the text, and get a separate response for each match.

However, if you want to match a string against any of the listed expressions (the results would be joined with "or"), it would be more efficient to combine the query parts in a single regular expression with `|` and match it with regular `Grep` or `Match`.

When you call `MultiGrep` / `MultiMatch`, regular expressions are passed one per line using multiline string literals:

Example

```
$multi_match = Hyperscan::MultiMatch(@@a.*
.*x.*
.*axa.*@@);

SELECT
    $multi_match("a") AS a,     -- (true, false, false)
    $multi_match("axa") AS axa; -- (true, true, true)
```

Capture and Replace

`Hyperscan::Capture` if a string matches the specified regular expression, it returns the last substring matching the regular expression. `Hyperscan::Replace` replaces all occurrences of the specified regular expression with the specified string.

Hyperscan doesn't support advanced functionality for such operations. Although `Hyperscan::Capture` and `Hyperscan::Replace` are implemented for consistency, it's better to use the same-name functions from the Re2 library for any non-trivial capture and replace:

- Re2::Capture;
- Re2::Replace.

Usage example

```
$value = "xaaxaaXaa";

$match = Hyperscan::Match("a.*");
$grep = Hyperscan::Grep("axa");
$insensitive_grep = Hyperscan::Grep("(?i)axaa$");
$multi_match = Hyperscan::MultiMatch(@@a.*
.*a.*
.*a
.*axa.*@@);

$capture = Hyperscan::Capture(".*a{2}.*");
$capture_many = Hyperscan::Capture(".*x(a+).*");
$replace = Hyperscan::Replace("xa");

SELECT
    $match($value) AS match,                        -- false
    $grep($value) AS grep,                          -- true
    $insensitive_grep($value) AS insensitive_grep,  -- true
    $multi_match($value) AS multi_match,            -- (false, true, true, true)
    $multi_match($value).0 AS some_multi_match,     -- false
    $capture($value) AS capture,                    -- "xaa"
    $capture_many($value) AS capture_many,          -- "xa"
    $replace($value, "b") AS replace                -- "babaXaa"
;
```

Ip

The `Ip` module supports both the IPv4 and IPv6 addresses. By default, they are represented as binary strings of 4 and 16 bytes, respectively.

List of functions

- `Ip::FromString(String{Flags:AutoMap}) -> String?` - From a human-readable representation to a binary representation.
- `Ip::SubnetFromString(String{Flags:AutoMap}) -> String?` - From a human-readable representation of subnet to a binary representation.
- `Ip::ToString(String{Flags:AutoMap}) -> String?` - From a binary representation to a human-readable representation.
- `Ip::SubnetToString(String{Flags:AutoMap}) -> String?` - From a binary representation of subnet to a human-readable representation.
- `Ip::IsIPv4(String?) -> Bool`
- `Ip::IsIPv6(String?) -> Bool`
- `Ip::IsEmbeddedIPv4(String?) -> Bool`
- `Ip::ConvertToIPv6(String{Flags:AutoMap}) -> String`: IPv6 remains unchanged, and IPv4 becomes embedded in IPv6
- `Ip::GetSubnet(String{Flags:AutoMap}, [Uint8?]) -> String`: The second argument is the subnet size, by default it's 24 for IPv4 and 64 for IPv6
- `Ip::GetSubnetByMask(String{Flags:AutoMap}, String{Flags:AutoMap}) -> String`: The first argument is the base address, the second argument is the bit mask of a desired subnet.
- `Ip::SubnetMatch(String{Flags:AutoMap}, String{Flags:AutoMap}) -> Bool`: The first argument is a subnet, the second argument is a subnet or an address.

Examples

```
SELECT Ip::IsEmbeddedIPv4(
  Ip::FromString("::ffff:77.75.155.3")
); -- true

SELECT
  Ip::ToString(
    Ip::GetSubnet(
      Ip::FromString("213.180.193.3")
    )
  ); -- "213.180.193.0"

SELECT
  Ip::SubnetMatch(
    Ip::SubnetFromString("192.168.0.1/16"),
    Ip::FromString("192.168.1.14"),
  ); -- true

SELECT
  Ip::ToString(
    Ip::GetSubnetByMask(
      Ip::FromString("192.168.0.1"),
      Ip::FromString("255.255.0.0")
    )
  ); -- "192.168.0.0"
```

KNN

Introduction

One specific case of vector search is the k-NN problem, where it is required to find the `k` nearest points to the query point. This can be useful in various applications such as image classification, recommendation systems, etc.

The k-NN problem solution is divided into two major subclasses of methods: exact and approximate.

Exact method

The foundation of the exact method is the calculation of the distance from the query vector to all the vectors in the dataset. This algorithm, also known as the naive approach or brute force method, has a runtime of `O(dn)`, where `n` is the number of vectors in the dataset, and `d` is their dimensionality.

Exact vector search is best utilized if the complete enumeration of the vectors occurs within acceptable time limits. This includes cases where they can be pre-filtered based on some condition, such as a user identifier. In such instances, the exact method may perform faster than the current implementation of vector indexes.

Main advantages:

- No need for additional data structures, such as specialized vector indexes.
- Full support for transactions, including in strict consistency mode.
- Instant execution of data modification operations: insertion, update, deletion.

Approximate methods

Approximate methods do not perform a complete enumeration of the initial data. This allows significantly speeding up the search process, although it might lead to some reduction in the quality of the results.

Scalar Quantization is a method of reducing vector dimensionality, where a set of coordinates is mapped into a space of smaller dimensions.

YDB supports vector searching for vector types `Float`, `Int8`, `Uint8`, and `Bit`. Consequently, it is possible to apply scalar quantization to transform data from `Float` to any of these types.

Scalar quantization reduces the time required for reading and writing data by decreasing the number of bytes. For example, when quantizing from `Float` to `Bit`, each vector is reduced by 32 times.

Approximate vector search without an index uses a very simple additional data structure - a set of vectors with other quantization. This allows the use of a simple search algorithm: first, a rough preliminary search is performed on the compressed vectors, followed by refining the results on the original vectors.

Main advantages:

- Full support for transactions, including in strict consistency mode.
- Instant application of data modification operations: insertion, update, deletion.

> **Note**
>
> It is recommended to measure if such quantization provides sufficient accuracy/recall.

Data types

In mathematics, a vector of real or integer numbers is used to store points.
In this module, vectors are stored in the `String` data type, which is a binary serialized representation of a vector.

Functions

Vector functions are implemented as user-defined functions (UDF) in the `Knn` module.

Functions for converting between vector and binary representations

Conversion functions are needed to serialize vectors into an internal binary representation and vice versa.

All serialization functions wrap returned `String` data into Tagged types.

The binary representation of the vector can be stored in the YDB table column.

> **Note**
>
> Currently YDB does not support storing `Tagged`, so before storing binary representation vectors you must call Untag.

> **Note**
>
> Currently YDB does not support building an index for vectors with bit quantization `BitVector`.

Function signatures

```
Knn::ToBinaryStringFloat(List<Float>{Flags:AutoMap})->Tagged<String, "FloatVector">
Knn::ToBinaryStringUint8(List<Uint8>{Flags:AutoMap})->Tagged<String, "Uint8Vector">
Knn::ToBinaryStringInt8(List<Int8>{Flags:AutoMap})->Tagged<String, "Int8Vector">
Knn::ToBinaryStringBit(List<Double>{Flags:AutoMap})->Tagged<String, "BitVector">
Knn::ToBinaryStringBit(List<Float>{Flags:AutoMap})->Tagged<String, "BitVector">
Knn::ToBinaryStringBit(List<Uint8>{Flags:AutoMap})->Tagged<String, "BitVector">
Knn::ToBinaryStringBit(List<Int8>{Flags:AutoMap})->Tagged<String, "BitVector">
Knn::FloatFromBinaryString(String{Flags:AutoMap})->List<Float>?
```

Convert format

Conversion functions for vector data convert an array of elements into a byte string with the following format:

- **Main part** — a contiguous array of elements (knn-serializer.h)
- **Type** — 1 byte at the end of the string that specifies the data type (knn-defines.h):
  `1` — `Float` (4 bytes per element)
  `2` — `Uint8` (1 byte per element)
  `3` — `Int8` (1 byte per element)
  `10` — `Bit` (1 bit per element)

For example, a vector of 5 elements of type `Float` will be serialized into a 21-byte string:
4 bytes × 5 elements (main part) + 1 byte (type) = 21 bytes.

Implementation details

The `ToBinaryStringBit` function maps coordinates that are greater than `0` to `1`. All other coordinates are mapped to `0`.

Distance and similarity functions

The distance and similarity functions take two lists of real numbers as input and return the distance/similarity between them.

> **Note**
>
> Distance functions return small values for close vectors, while similarity functions return large values for close vectors. This should be taken into account when defining the sorting order.

Similarity functions:

- inner product `InnerProductSimilarity`, it's the dot product, also known as the scalar product (sum of products of coordinates)
- cosine similarity `CosineSimilarity` (dot product divided by product of vector lengths)

Distance functions:

- cosine distance `CosineDistance` (1 - cosine similarity)
- manhattan distance `ManhattanDistance`, also known as `L1 distance` (sum of modules of coordinate differences)
- euclidean distance `EuclideanDistance`, also known as `L2 distance` (square root of the sum of squares of coordinate differences)

Function signatures

```
Knn::InnerProductSimilarity(String{Flags:AutoMap}, String{Flags:AutoMap})->Float?
Knn::CosineSimilarity(String{Flags:AutoMap}, String{Flags:AutoMap})->Float?
Knn::CosineDistance(String{Flags:AutoMap}, String{Flags:AutoMap})->Float?
Knn::ManhattanDistance(String{Flags:AutoMap}, String{Flags:AutoMap})->Float?
Knn::EuclideanDistance(String{Flags:AutoMap}, String{Flags:AutoMap})->Float?
```

In case of mismatched lengths or formats, these functions return `NULL`.

> **Note**
>
> All distance and similarity functions support overloads when first or second arguments are `Tagged<String, "FloatVector">`, `Tagged<String, "Uint8Vector">`, `Tagged<String, "Int8Vector">`, `Tagged<String, "BitVector">`.
>
> If both arguments are `Tagged`, tag values should match, or the query will raise an error.
>
> Example:
>
> ```
> Error: Failed to find UDF function: Knn.CosineDistance, reason: Error: Module: Knn, function: Cosi
> neDistance, error: Arguments should have same tags, but 'FloatVector' is not equal to 'Uint8Vecto
> r'
> ```

Exact search examples

Creating a table

```
CREATE TABLE Facts (
    id Uint64,        -- Id of fact
    user Utf8,        -- User name
    fact Utf8,        -- Human-readable description of a user fact
    embedding String, -- Binary representation of embedding vector (result of Knn::ToBinaryStringFloat)
    PRIMARY KEY (id)
);
```

Adding vectors

```
$vector = [1.f, 2.f, 3.f, 4.f];
UPSERT INTO Facts (id, user, fact, embedding)
VALUES (123, "Williams", "Full name is John Williams", Untag(Knn::ToBinaryStringFloat($vector), "FloatVecto
r"));
```

Exact search of K nearest vectors

```
$K = 10;
$TargetEmbedding = Knn::ToBinaryStringFloat([1.2f, 2.3f, 3.4f, 4.5f]);

SELECT * FROM Facts
WHERE user="Williams"
ORDER BY Knn::CosineDistance(embedding, $TargetEmbedding)
LIMIT $K;
```

Exact search of vectors in radius R

```
$R = 0.1f;
$TargetEmbedding = Knn::ToBinaryStringFloat([1.2f, 2.3f, 3.4f, 4.5f]);

SELECT * FROM Facts
WHERE Knn::CosineDistance(embedding, $TargetEmbedding) < $R;
```

Approximate search examples

This example differs from the exact search example by using bit quantization.

This allows to first do a approximate preliminary search by the `embedding_bit` column, and then refine the results by the original vector column `embegging`.

Creating a table

```
CREATE TABLE Facts (
    id Uint64,            -- Id of fact
    user Utf8,            -- User name
    fact Utf8,            -- Human-readable description of a user fact
    embedding String,     -- Binary representation of embedding vector (result of Knn::ToBinaryStringFloat)
    embedding_bit String, -- Binary representation of embedding vector (result of Knn::ToBinaryStringBit)
    PRIMARY KEY (id)
);
```

Adding vectors

```
$vector = [1.f, 2.f, 3.f, 4.f];
UPSERT INTO Facts (id, user, fact, embedding, embedding_bit)
VALUES (123, "Williams", "Full name is John Williams", Untag(Knn::ToBinaryStringFloat($vector), "FloatVecto
r"), Untag(Knn::ToBinaryStringBit($vector), "BitVector"));
```

Scalar quantization

An ML model can do quantization, or it can be done manually with YQL.

Below there is a quantization example in YQL.

Float -> Int8

```
$MapInt8 = ($x) -> {
    $min = -5.0f;
    $max =  5.0f;
    $range = $max - $min;
  RETURN CAST(Math::Round(IF($x < $min, -127, IF($x > $max, 127, ($x / $range) * 255))) As Int8)
};

$FloatList = [-1.2f, 2.3f, 3.4f, -4.7f];
SELECT ListMap($FloatList, $MapInt8);
```

Approximate search of K nearest vectors: bit quantization

Approximate search algorithm:

- an approximate search is performed using bit quantization;
- an approximate list of vectors is obtained;
- we search this list without using quantization.

```
$K = 10;
$Target = [1.2f, 2.3f, 3.4f, 4.5f];
$TargetEmbeddingBit = Knn::ToBinaryStringBit($Target);
$TargetEmbeddingFloat = Knn::ToBinaryStringFloat($Target);

$Ids = SELECT id FROM Facts
ORDER BY Knn::CosineDistance(embedding_bit, $TargetEmbeddingBit)
LIMIT $K * 10;

SELECT * FROM Facts
WHERE id IN $Ids
ORDER BY Knn::CosineDistance(embedding, $TargetEmbeddingFloat)
LIMIT $K;
```

Math

A set of wrappers around the functions from the libm library and the Yandex utilities.

Constants

List of functions

- `Math::Pi() -> Double`
- `Math::E() -> Double`
- `Math::Eps() -> Double`

Examples

```
SELECT Math::Pi();  -- 3.141592654
SELECT Math::E();   -- 2.718281828
SELECT Math::Eps(); -- 2.220446049250313e-16
```

(Double) -> Bool

List of functions

- `Math::IsInf(Double{Flags:AutoMap}) -> Bool`
- `Math::IsNaN(Double{Flags:AutoMap}) -> Bool`
- `Math::IsFinite(Double{Flags:AutoMap}) -> Bool`

Examples

```
SELECT Math::IsNaN(0.0/0.0);    -- true
SELECT Math::IsFinite(1.0/0.0); -- false
```

(Double) -> Double

List of functions

- `Math::Abs(Double{Flags:AutoMap}) -> Double`
- `Math::Acos(Double{Flags:AutoMap}) -> Double`
- `Math::Asin(Double{Flags:AutoMap}) -> Double`
- `Math::Asinh(Double{Flags:AutoMap}) -> Double`
- `Math::Atan(Double{Flags:AutoMap}) -> Double`
- `Math::Cbrt(Double{Flags:AutoMap}) -> Double`
- `Math::Ceil(Double{Flags:AutoMap}) -> Double`
- `Math::Cos(Double{Flags:AutoMap}) -> Double`
- `Math::Cosh(Double{Flags:AutoMap}) -> Double`
- `Math::Erf(Double{Flags:AutoMap}) -> Double`
- `Math::ErfInv(Double{Flags:AutoMap}) -> Double`
- `Math::ErfcInv(Double{Flags:AutoMap}) -> Double`
- `Math::Exp(Double{Flags:AutoMap}) -> Double`
- `Math::Exp2(Double{Flags:AutoMap}) -> Double`
- `Math::Fabs(Double{Flags:AutoMap}) -> Double`
- `Math::Floor(Double{Flags:AutoMap}) -> Double`
- `Math::Lgamma(Double{Flags:AutoMap}) -> Double`
- `Math::Rint(Double{Flags:AutoMap}) -> Double`
- `Math::Sigmoid(Double{Flags:AutoMap}) -> Double`
- `Math::Sin(Double{Flags:AutoMap}) -> Double`
- `Math::Sinh(Double{Flags:AutoMap}) -> Double`
- `Math::Sqrt(Double{Flags:AutoMap}) -> Double`
- `Math::Tan(Double{Flags:AutoMap}) -> Double`
- `Math::Tanh(Double{Flags:AutoMap}) -> Double`
- `Math::Tgamma(Double{Flags:AutoMap}) -> Double`
- `Math::Trunc(Double{Flags:AutoMap}) -> Double`
- `Math::Log(Double{Flags:AutoMap}) -> Double`
- `Math::Log2(Double{Flags:AutoMap}) -> Double`
- `Math::Log10(Double{Flags:AutoMap}) -> Double`

Examples

```
SELECT Math::Sqrt(256);     -- 16
SELECT Math::Trunc(1.2345); -- 1
```

(Double, Double) -> Double

List of functions

- `Math::Atan2(Double{Flags:AutoMap}, Double{Flags:AutoMap}) -> Double`
- `Math::Fmod(Double{Flags:AutoMap}, Double{Flags:AutoMap}) -> Double`
- `Math::Hypot(Double{Flags:AutoMap}, Double{Flags:AutoMap}) -> Double`

- `Math::Pow(Double{Flags:AutoMap}, Double{Flags:AutoMap}) -> Double`
- `Math::Remainder(Double{Flags:AutoMap}, Double{Flags:AutoMap}) -> Double`

Examples

```
SELECT Math::Atan2(1, 0);       -- 1.570796327
SELECT Math::Remainder(2.1, 2); -- 0.1
```

(Double, Int32) -> Double

List of functions

- `Math::Ldexp(Double{Flags:AutoMap}, Int32{Flags:AutoMap}) -> Double`
- `Math::Round(Double{Flags:AutoMap}, [Int32?]) -> Double`: The second argument indicates the power of 10 to which we round (it's negative for decimal digits and positive for rounding to tens, thousands, or millions); the default value is 0

Examples

```
SELECT Math::Pow(2, 10);        -- 1024
SELECT Math::Round(1.2345, -2); -- 1.23
```

(Double, Double, [Double?]) -> Bool

List of functions

- `Math::FuzzyEquals(Double{Flags:AutoMap}, Double{Flags:AutoMap}, [Double?]) -> Bool`: Compares two Doubles for being inside the neighborhood specified by the third argument; the default value is 1.0e-13

Examples

```
SELECT Math::FuzzyEquals(1.01, 1.0, 0.05); -- true
```

Functions for computing remainders

List of functions

- `Math::Mod(Int64{Flags:AutoMap}, Int64) -> Int64?`
- `Math::Rem(Int64{Flags:AutoMap}, Int64) -> Int64?`

These functions behave similarly to the built-in % operator in the case of non-negative arguments. The differences are noticeable in the case of negative arguments:

- `Math::Mod` preserves the sign of the second argument (the denominator).
- `Math::Rem` preserves the sign of the first argument (the numerator).

Functions return null if the divisor is zero.

Examples

```
SELECT Math::Mod(-1, 7);        -- 6
SELECT Math::Rem(-1, 7);        -- -1
```

Pcre

The Pcre library is currently an alias to Hyperscan.

Currently available engines:

- Hyperscan (Intel)
- Pire (Yandex)
- Re2 (Google)

All three modules provide approximately the same set of functions with an identical interface. This lets you switch between them with minimal changes to a query.

Inside Hyperscan, there are several implementations that use different sets of processor instructions, with the relevant instruction automatically selected based on the current processor. In HyperScan, some functions support backtracking (referencing the previously found part of the string). Those functions are implemented through hybrid use of the two libraries: Hyperscan and libpcre.

Pire (Perl Incompatible Regular Expressions) is a very fast library of regular expressions developed by Yandex. At the lower level, it scans the input string once, without any lookaheads or rollbacks, spending 5 machine instructions per character (on x86 and x86_64). However, since the library almost hasn't been developed since 2011-2013 and its name says "Perl incompatible", you may need to adapt your regular expressions a bit.

Hyperscan and Pire are best-suited for Grep and Match.

The Re2 module uses google::RE2 that offers a wide range of features (see the official documentation). The main benefit of the Re2 is its advanced Capture and Replace functionality. Use this library, if you need those functions.

Pire

List of functions

- `Pire::Grep(pattern:String) -> (string:String?) -> Bool`
- `Pire::Match(pattern:String) -> (string:String?) -> Bool`
- `Pire::MultiGrep(pattern:String) -> (string:String?) -> Tuple<Bool, Bool, ...>`
- `Pire::MultiMatch(pattern:String) -> (string:String?) -> Tuple<Bool, Bool, ...>`
- `Pire::Capture(pattern:String) -> (string:String?) -> String?`
- `Pire::Replace(pattern:String) -> (string:String?, replacement:String) -> String?`

One of the options to match regular expressions in YQL is to use Pire (Perl Incompatible Regular Expressions). This is a very fast library of regular expressions developed at Yandex: at the lower level, it looks up the input string once, without any lookaheads or rollbacks, spending 5 machine instructions per character (on x86 and x86_64).

The speed is achieved by using the reasonable restrictions:

- Pire is primarily focused at checking whether a string matches a regular expression.
- The matching substring can also be returned (by Capture), but with restrictions (a match with only one group is returned).

By default, all functions work in the single-byte mode. However, if the regular expression is a valid UTF-8 string but is not a valid ASCII string, the UTF-8 mode is enabled automatically.

To enable the Unicode mode, you can put one character that's beyond ASCII with the `?` operator, for example: `\\w+я?`.

Call syntax

To avoid compiling a regular expression at each table row, wrap the function call by a named expression:

```
$re = Pire::Grep("\\d+"); -- create a callable value to match a specific regular expression
SELECT * FROM table WHERE $re(key); -- use it to filter the table
```

Alert

When escaping special characters in a regular expression, be sure to use the second slash, since all the standard string literals in SQL can accept C-escaped strings, and the `\d` sequence is not a valid sequence (even if it were, it wouldn't search for numbers as intended).

You can enable the case-insensitive mode by specifying, at the beginning of the regular expression, the flag `(?i)`.

Examples

```
$value = "xaaxaaxaa";
$match = Pire::Match("a.*");
$grep = Pire::Grep("axa");
$insensitive_grep = Pire::Grep("(?i)axa");
$multi_match = Pire::MultiMatch(@@a.*
.*a.*
.*a
.*axa.*@@);
$capture = Pire::Capture(".*x(a).*");
$capture_many = Pire::Capture(".*x(a+).*");
$replace = Pire::Replace(".*x(a).*");

SELECT
  $match($value) AS match,                        -- false
  $grep($value) AS grep,                          -- true
  $insensitive_grep($value) AS insensitive_grep,  -- true
  $multi_match($value) AS multi_match,            -- (false, true, true, true)
  $multi_match($value).0 AS some_multi_match,     -- false
  $capture($value) AS capture,                    -- "a"
  $capture_many($value) AS capture_many,          -- "aa"
  $replace($value, "b") AS replace;               -- "xaaxaaxba"
```

Grep

Matches the regular expression with a **part of the string** (arbitrary substring).

Match

Matches **the whole string** against the regular expression.
To get a result similar to `Grep` (where substring matching is included), enclose the regular expression in `.*`. For example, use `.*foo.*` instead of `foo`.

MultiGrep/MultiMatch

Pire lets you match against multiple regular expressions in a single pass through the text and get a separate response for each match. Use the MultiGrep/MultiMatch functions to optimize the query execution speed. Be sure to do it carefully, since the size of the state machine used for matching grows exponentially with the number of regular expressions:

- If you want to match a string against any of the listed expressions (the results are joined with "or"), it would be much more efficient to combine the query parts in a single regular expression with `|` and match it using regular Grep or Match.
- Pire has a limit on the size of the state machine (YQL uses the default value set in the library). If you exceed the limit, the error is raised at the start of the query: `Failed to glue up regexes, probably the finite state machine appeared to be too large`.

When you call MultiGrep/MultiMatch, regular expressions are passed one per line using multiline string literals:

Examples

```
$multi_match = Pire::MultiMatch(@@a.*
.*x.*
.*axa.*@@);

SELECT
    $multi_match("a") AS a,      -- (true, false, false)
    $multi_match("axa") AS axa;  -- (true, true, true)
```

Capture

If a string matches the specified regular expression, it returns a substring that matches the group enclosed in parentheses in the regular expression.
Capture is non-greedy: the shortest possible substring is returned.

> **Alert**
>
> The expression must contain only **one** group in parentheses. `NULL` (empty Optional) is returned in case of no match.

If the above limitations and features are unacceptable for some reason, we recommend that you consider Re2::Capture.

REPLACE

Pire doesn't support replace based on a regular expression. `Pire::Replace` implemented in YQL is a simplified emulation using `Capture`. It may run correctly, if the substring occurs more than once in the source string.

As a rule, it's better to use Re2::Replace instead.

Re2

List of functions

```
Re2::Grep(pattern:String, options:Struct<...>?) -> (string:String?) -> Bool
Re2::Match(pattern:String, options:Struct<...>?) -> (string:String?) -> Bool
Re2::Capture(pattern:String, options:Struct<...>?) -> (string:String?) -> Struct<_1:String?,foo:String?,...>
Re2::FindAndConsume(pattern:String, options:Struct<...>?) -> (string:String?) -> List<String>
Re2::Replace(pattern:String, options:Struct<...>?) -> (string:String?, replacement:String) -> String?
Re2::Count(pattern:String, options:Struct<...>?) -> (string:String?) -> Uint32
Re2::Options([CaseSensitive:Bool?,DotNl:Bool?,Literal:Bool?,LogErrors:Bool?,LongestMatch:Bool?,MaxMem:Uint6
4?,NeverCapture:Bool?,NeverNl:Bool?,OneLine:Bool?,PerlClasses:Bool?,PosixSyntax:Bool?,Utf8:Bool?,WordBoundar
y:Bool?]) -> Struct<CaseSensitive:Bool,DotNl:Bool,Literal:Bool,LogErrors:Bool,LongestMatch:Bool,MaxMem:Uint6
4,NeverCapture:Bool,NeverNl:Bool,OneLine:Bool,PerlClasses:Bool,PosixSyntax:Bool,Utf8:Bool,WordBoundary:Bool>
```

The Re2 module supports regular expressions based on google::RE2 with a wide range of features provided (see the official documentation).

By default, the UTF-8 mode is enabled automatically if the regular expression is a valid UTF-8-encoded string, but is not a valid ASCII string. You can manually control the settings of the re2 library, if you pass the result of the `Re2::Options` function as the second argument to other module functions, next to the regular expression.

Warning

Make sure to double all the backslashes in your regular expressions (if they are within a quoted string): standard string literals are treated as C-escaped strings in SQL. You can also format regular expressions as raw strings `@@regexp@@`: double slashes are not needed in this case.

Examples

```
$value = "xaaxaaxaa";
$options = Re2::Options(false AS CaseSensitive);
$match = Re2::Match("[ax]+\\d");
$grep = Re2::Grep("a.*");
$capture = Re2::Capture(".*(?P<foo>xa?)(a{2,}).*");
$replace = Re2::Replace("x(a+)x");
$count = Re2::Count("a", $options);

SELECT
  $match($value) AS match,               -- false
  $grep($value) AS grep,                 -- true
  $capture($value) AS capture,           -- (_0: 'xaaxaaxaa', _1: 'aa', foo: 'x')
  $capture($value)._1 AS capture_member, -- "aa"
  $replace($value, "b\\1z") AS replace,  -- "baazaaxaa"
  $count($value) AS count;               -- 6
```

Re2::Grep / Re2::Match

If you leave out the details of implementation and syntax of regular expressions, those functions are totally similar to the same-name functions from the Pire module. With other things equal and no specific preferences, we recommend that you use `Pire::Grep or Pire::Match`.

You can call the `Re2::Grep` function by using a `REGEXP` expression (see the basic expression syntax).

For example, the following two queries are equivalent (also in terms of computing efficiency):

- `$grep = Re2::Grep("b+"); SELECT $grep("aaabccc");`
- `SELECT "aaabccc" REGEXP "b+";`

Re2::Capture

Unlike Pire::Capture, `Re2::Capture` supports multiple and named capturing groups.
Result type: a structure with the fields of the type `String?`.

- Each field corresponds to a capturing group with the applicable name.
- For unnamed groups, the following names are generated: `_1`, `_2`, etc.
- The result always includes the `_0` field containing the entire substring matching the regular expression.

For more information about working with structures in YQL, see the section on containers.

Re2::FindAndConsume

Searches for all occurrences of the regular expression in the passed text and returns a list of values corresponding to the parenthesized part of the regular expression for each occurrence.

Re2::Replace

Works as follows:

- In the input string (first argument), all the non-overlapping substrings matching the regular expression are replaced by the specified string (second argument).
- In the replacement string, you can use the contents of capturing groups from the regular expression using back-references in the format: `\\1`, `\\2` etc. The `\\0` back-reference stands for the whole substring that matches the regular expression.

Re2::Count

Returns the number of non-overlapping substrings of the input string that have matched the regular expression.

Re2::Options

Notes on Re2::Options from the official repository

Parameter	Default	Comments
CaseSensitive:Bool?	true	match is case-sensitive (regexp can override with (?i) unless in posix_syntax mode)
DotNl:Bool?	false	let `.` match `\n` (default)
Literal:Bool?	false	interpret string as literal, not regexp
LogErrors:Bool?	true	log syntax and execution errors to ERROR
LongestMatch:Bool?	false	search for longest match, not first match
MaxMem:Uint64?	-	(see below) approx. max memory footprint of RE2
NeverCapture:Bool?	false	parse all parents as non-capturing
NeverNl:Bool?	false	never match \n, even if it is in regexp
PosixSyntax:Bool?	false	restrict regexps to POSIX egrep syntax
Utf8:Bool?	true	text and pattern are UTF-8; otherwise Latin-1
The following options are only consulted when PosixSyntax == true. When PosixSyntax == false, these features are always enabled and cannot be turned off; to perform multi-line matching in that case, begin the regexp with (?m).		
PerlClasses:Bool?	false	allow Perl's \d \s \w \D \S \W
WordBoundary:Bool?	false	allow Perl's \b \B (word boundary and not)
OneLine:Bool?	false	^ and $ only match beginning and end of text

It is not recommended to use Re2::Options in the code. Most parameters can be replaced with regular expression flags.

Flag usage examples

```
$value = "Foo bar FOO"u;
-- enable case-insensitive mode
$capture = Re2::Capture(@@(?i)(foo)@@);

SELECT
    $capture($value) AS capture; -- ("_0": "Foo", "_1": "Foo")

$capture = Re2::Capture(@@(?i)(?P<foo>FOO).*(?P<bar>bar)@@);

SELECT
    $capture($value) AS capture; -- ("_0": "Foo bar", "bar": "bar", "foo": "Foo")
```

In both cases, the word FOO will be found. Using the raw string @@regexp@@ lets you avoid double slashes.

Roaring

Introduction

Bitsets, also called bitmaps, are commonly used as fast data structures. Unfortunately, they can use too much memory. To compensate, we often use compressed bitmaps.

Roaring bitmaps are compressed bitmaps which tend to outperform conventional compressed bitmaps such as WAH, EWAH or Concise. In some instances, roaring bitmaps can be hundreds of times faster and they often offer significantly better compression. They can even be faster than uncompressed bitmaps.

Implementation

You can work with Roaring bitmaps in YDB using a set of user-defined functions (UDFs) in the `Roaring` module. These functions provide the ability to work with 32-bit Roaring bitmaps. To do this, the data must be serialized in the format for 32-bit bitmaps described in the specification. This can be done using a function available in the Roaring bitmap library itself.

Such libraries exist for many programming languages, such as Go. If the serialization happened on the client side, the application can then save the serialized bitmap in a column with the `String` type.

To work with Roaring bitmaps in a query, data from the `String` type must be deserialized into the Resource<roaring_bitmap> type. To save the data, you need to perform the reverse operation. After that, the application can read the updated bitmap from YDB and deserialize it.

Available methods

```
Roaring::Deserialize(String{Flags:AutoMap})->Resource<roaring_bitmap>
Roaring::FromUint32List(List<Uint32>{Flags:AutoMap})->Resource<roaring_bitmap>
Roaring::Serialize(Resource<roaring_bitmap>{Flags:AutoMap})->String
Roaring::Uint32List(Resource<roaring_bitmap>{Flags:AutoMap})->List<Uint32>

Roaring::Cardinality(Resource<roaring_bitmap>{Flags:AutoMap})->Uint32

Roaring::Or(Resource<roaring_bitmap>{Flags:AutoMap}, Resource<roaring_bitmap>{Flags:AutoMap})->Resource<roari
ng_bitmap>
Roaring::OrWithBinary(Resource<roaring_bitmap>{Flags:AutoMap}, String{Flags:AutoMap})->Resource<roaring_bitma
p>

Roaring::And(Resource<roaring_bitmap>{Flags:AutoMap}, Resource<roaring_bitmap>{Flags:AutoMap})->Resource<roar
ing_bitmap>
Roaring::AndWithBinary(Resource<roaring_bitmap>{Flags:AutoMap}, String{Flags:AutoMap})->Resource<roaring_bitm
ap>

Roaring::AndNot(Resource<roaring_bitmap>{Flags:AutoMap}, Resource<roaring_bitmap>{Flags:AutoMap})->Resource<r
oaring_bitmap>
Roaring::AndNotWithBinary(Resource<roaring_bitmap>{Flags:AutoMap}, String{Flags:AutoMap})->Resource<roaring_b
itmap>

Roaring::RunOptimize(Resource<roaring_bitmap>{Flags:AutoMap})->Resource<roaring_bitmap>
```

Serialization and deserialization

Two functions, `Deserialize` and `FromUint32List`, are available for creating `Resource<roaring_bitmap>`. The second function allows creating a Roaring bitmap from a list of unsigned integers, i.e., without the need to use the Roaring bitmap library code to create a binary representation.

YDB does not store data with the `Resource` type, so the created bitmap must be converted to a binary representation using the `Serialize` method.

To use the resulting bitmap, for example, in a `WHERE` condition, the `Uint32List` method is provided. This method returns a list of unsigned integers from the `Resource<roaring_bitmap>`.

Bitwise operations

Currently, three modifying binary operations with bitmaps are supported:

- `Or`
- `And`
- `AndNot`

The operations are modifying, meaning that they modify the `Resource<roaring_bitmap>` passed as the first argument. Each of these operations has a version with the `WithBinary` suffix, which allows working with the binary representation without having to deserialize it into the `Resource<roaring_bitmap>` type. The implementation of these methods still has to deserialize the data to perform the operation, but it does not create an intermediate `Resource`, thereby saving resources.

Other operations

The `Cardinality` function is provided to obtain the number of bits set to 1 in the `Resource<roaring_bitmap>`.

After the bitmap has been constructed or modified, it can be optimized using the `RunOptimize` method. The internal format of a Roaring bitmap can use containers with better representations for different bit sequences.

Examples

```
$b = Roaring::FromUint32List(AsList(42));
$b = Roaring::Or($b, Roaring::FromUint32List(AsList(56)));

SELECT Roaring::Uint32List($b) AS `Or`; -- [42, 56]
```

```
$b1 = Roaring::FromUint32List(AsList(10, 567, 42));
$b2 = Roaring::FromUint32List(AsList(42));

$b2ser = Roaring::Serialize($b2); -- save this to String column

SELECT Roaring::Cardinality(Roaring::AndWithBinary($b1, $b2ser)) AS Cardinality; -- 1

SELECT Roaring::Uint32List(Roaring::And($b1, $b2)) AS `And`; -- [42]
SELECT Roaring::Uint32List(Roaring::AndWithBinary($b1, $b2ser)) AS AndWithBinary; -- [42]
```

```
$b1 = Roaring::FromUint32List(AsList(10, 567, 42));
$b2 = Roaring::FromUint32List(AsList(42));

$b2ser = Roaring::Serialize($b2); -- save this to String column

SELECT Roaring::Cardinality(Roaring::AndNotWithBinary($b1, $b2ser)) AS Cardinality; -- 2

SELECT Roaring::Uint32List(Roaring::AndNot($b1, $b2)) AS AndNot; -- [10,567]
SELECT Roaring::Uint32List(Roaring::AndNotWithBinary($b1, $b2ser)) AS AndNotWithBinary; -- [10,567]
```

String

Functions for ASCII strings:

List of functions

- `String::Base64Encode(String{Flags:AutoMap}) -> String`
- `String::Base64Decode(String) -> String?`
- `String::Base64StrictDecode(String) -> String?`
- `String::EscapeC(String{Flags:AutoMap}) -> String`
- `String::UnescapeC(String{Flags:AutoMap}) -> String`
- `String::HexEncode(String{Flags:AutoMap}) -> String`
- `String::HexDecode(String) -> String?`
- `String::EncodeHtml(String{Flags:AutoMap}) -> String`
- `String::DecodeHtml(String{Flags:AutoMap}) -> String`
- `String::CgiEscape(String{Flags:AutoMap}) -> String`
- `String::CgiUnescape(String{Flags:AutoMap}) -> String`
- `String::Strip(String{Flags:AutoMap}) -> String`
- `String::Collapse(String{Flags:AutoMap}) -> String`
- `String::CollapseText(String{Flags:AutoMap}, Uint64) -> String`
- `String::Contains(String?, String) -> Bool`
- `String::Find(String{Flags:AutoMap}, String, [Uint64?]) -> Int64` : Returns the first position found or -1. The optional argument is the offset from the beginning of the string.
- `String::ReverseFind(String{Flags:AutoMap}, String, [Uint64?]) -> Int64` : Returns the last position found or -1. The optional argument is the offset from the beginning of the string.
- `String::HasPrefix(String?, String) -> Bool`
- `String::HasPrefixIgnoreCase(String?, String) -> Bool`
- `String::StartsWith(String?, String) -> Bool`
- `String::StartsWithIgnoreCase(String?, String) -> Bool`
- `String::HasSuffix(String?, String) -> Bool`
- `String::HasSuffixIgnoreCase(String?, String) -> Bool`
- `String::EndsWith(String?, String) -> Bool`
- `String::EndsWithIgnoreCase(String?, String) -> Bool`
- `String::Substring(String{Flags:AutoMap}, [Uint64?, Uint64?]) -> String`
- `String::AsciiToLower(String{Flags:AutoMap}) -> String` : Changes only Latin characters. For working with other alphabets, see Unicode::ToLower
- `String::AsciiToUpper(String{Flags:AutoMap}) -> String` : Changes only Latin characters. For working with other alphabets, see Unicode::ToUpper
- `String::AsciiToTitle(String{Flags:AutoMap}) -> String` : Changes only Latin characters. For working with other alphabets, see Unicode::ToTitle
- `String::SplitToList( String?, String, [ DelimeterString:Bool?, SkipEmpty:Bool?, Limit:Uint64? ]) -> List<String>`

  The first argument is the source string
  The second argument is a delimiter
  The third argument includes the following parameters:

  - DelimeterString:Bool? — treating a delimiter as a string (true, by default) or a set of characters "any of" (false)
  - SkipEmpty:Bool? — whether to skip empty strings in the result, is false by default
  - Limit:Uint64? — Limits the number of fetched components (unlimited by default); if the limit is exceeded, the raw suffix of the source string is returned in the last item
- `String::JoinFromList(List<String>{Flags:AutoMap}, String) -> String`
- `String::ToByteList(List<String>{Flags:AutoMap}) -> List<Byte>`
- `String::FromByteList(List<Uint8>) -> String`
- `String::ReplaceAll(String{Flags:AutoMap}, String, String) -> String` : Arguments: input, find, replacement
- `String::ReplaceFirst(String{Flags:AutoMap}, String, String) -> String` : Arguments: input, find, replacement
- `String::ReplaceLast(String{Flags:AutoMap}, String, String) -> String` : Arguments: input, find, replacement
- `String::RemoveAll(String{Flags:AutoMap}, String) -> String` : The second argument is interpreted as an unordered set of characters to delete
- `String::RemoveFirst(String{Flags:AutoMap}, String) -> String` : An unordered set of characters in the second argument, only the first encountered character from set is deleted
- `String::RemoveLast(String{Flags:AutoMap}, String) -> String` : An unordered set of characters in the second argument, only the last encountered character from the set is deleted
- `String::IsAscii(String{Flags:AutoMap}) -> Bool`
- `String::IsAsciiSpace(String{Flags:AutoMap}) -> Bool`
- `String::IsAsciiUpper(String{Flags:AutoMap}) -> Bool`
- `String::IsAsciiLower(String{Flags:AutoMap}) -> Bool`
- `String::IsAsciiAlpha(String{Flags:AutoMap}) -> Bool`
- `String::IsAsciiAlnum(String{Flags:AutoMap}) -> Bool`
- `String::IsAsciiHex(String{Flags:AutoMap}) -> Bool`
- `String::LevensteinDistance(String{Flags:AutoMap}, String{Flags:AutoMap}) -> Uint64`
- `String::LeftPad(String{Flags:AutoMap}, Uint64, [String?]) -> String`
- `String::RightPad(String{Flags:AutoMap}, Uint64) -> String`
- `String::Hex(Uint64{Flags:AutoMap}) -> String`

- `String::SHex(Int64{Flags:AutoMap}) -> String`
- `String::Bin(Uint64{Flags:AutoMap}) -> String`
- `String::SBin(Int64{Flags:AutoMap}) -> String`
- `String::HexText(String{Flags:AutoMap}) -> String`
- `String::BinText(String{Flags:AutoMap}) -> String`
- `String::HumanReadableDuration(Uint64{Flags:AutoMap}) -> String`
- `String::HumanReadableQuantity(Uint64{Flags:AutoMap}) -> String`
- `String::HumanReadableBytes(Uint64{Flags:AutoMap}) -> String`
- `String::Prec(Double{Flags:AutoMap}, Uint64) -> String`
- `String::Reverse(String?) -> String?`

Alert

The functions from the String library don't support Cyrillic and can only work with ASCII characters. To work with UTF-8 encoded strings, use functions from Unicode.

Examples

```
SELECT String::Base64Encode("YQL"); -- "WVFM"
SELECT String::Base64Decode("WVFM"); -- "YQL"
SELECT String::Strip("YQL ");       -- "YQL"
SELECT String::SplitToList("1,2,3,4,5,6,7", ",", 3 as Limit); -- ["1", "2", "3", "4,5,6,7"]
```

Unicode

Functions for Unicode strings.

List of functions

- `Unicode::IsUtf(String) -> Bool`

  Checks whether a string is a valid UTF-8 sequence. For example, the string `"\xF0"` isn't a valid UTF-8 sequence, but the string `"\xF0\x9F\x90\xB1"` correctly describes a UTF-8 cat emoji.
- `Unicode::GetLength(Utf8{Flags:AutoMap}) -> Uint64`

  Returns the length of a utf-8 string in unicode code points. Surrogate pairs are counted as one character.

  ```
  SELECT Unicode::GetLength("жніўня"); -- 6
  ```
- `Unicode::Find(string:Utf8{Flags:AutoMap}, subString:Utf8, [pos:Uint64?]) -> Uint64?`
- `Unicode::RFind(string:Utf8{Flags:AutoMap}, subString:Utf8, [pos:Uint64?]) -> Uint64?`

  Finding the first (`RFind` - the last) occurrence of a substring in a string starting from the `pos` position. Returns the position of the first character from the found substring. In case of failure, returns Null.

  ```
  SELECT Unicode::Find("aaa", "bb"); -- Null
  ```
- `Unicode::Substring(string:Utf8{Flags:AutoMap}, from:Uint64?, len:Uint64?) -> Utf8`

  Returns a `string` substring starting with `from` that is `len` characters long. If the `len` argument is omitted, the substring is taken to the end of the source string.

  If `from` exceeds the length of the original string, an empty string `""` is returned.

  ```
  SELECT Unicode::Substring("0123456789abcdefghij", 10); -- "abcdefghij"
  ```
- The `Unicode::Normalize..` functions convert the passed UTF-8 string to a normalization form:
  - `Unicode::Normalize(Utf8{Flags:AutoMap}) -> Utf8` -- NFC
  - `Unicode::NormalizeNFD(Utf8{Flags:AutoMap}) -> Utf8`
  - `Unicode::NormalizeNFC(Utf8{Flags:AutoMap}) -> Utf8`
  - `Unicode::NormalizeNFKD(Utf8{Flags:AutoMap}) -> Utf8`
  - `Unicode::NormalizeNFKC(Utf8{Flags:AutoMap}) -> Utf8`
- `Unicode::Translit(string:Utf8{Flags:AutoMap}, [lang:String?]) -> Utf8`

  Transliterates with Latin letters the words from the passed string, consisting entirely of characters of the alphabet of the language passed by the second argument. If no language is specified, the words are transliterated from Russian. Available languages: "kaz", "rus", "tur", and "ukr".

  ```
  SELECT Unicode::Translit("Тот уголок земли, где я провел"); -- "Tot ugolok zemli, gde ya provel"
  ```
- `Unicode::LevensteinDistance(stringA:Utf8{Flags:AutoMap}, stringB:Utf8{Flags:AutoMap}) -> Uint64`

  Calculates the Levenshtein distance for the passed strings.
- `Unicode::Fold(Utf8{Flags:AutoMap}, [ Language:String?, DoLowerCase:Bool?, DoRenyxa:Bool?, DoSimpleCyr:Bool?, FillOffset:Bool? ]) -> Utf8`

  Performs case folding on the passed string.

  Parameters:

  - `Language` is set according to the same rules as in `Unicode::Translit()`.
  - `DoLowerCase` converts a string to lowercase letters, defaults to `true`.
  - `DoRenyxa` converts diacritical characters to similar Latin characters, defaults to `true`.
  - `DoSimpleCyr` converts diacritical Cyrillic characters to similar Latin characters, defaults to `true`.
  - `FillOffset` parameter is not used.

  ```
  SELECT Unicode::Fold("Kongreßstraße", false AS DoSimpleCyr, false AS DoRenyxa); -- "kongressstrasse"
  SELECT Unicode::Fold("çурт"); -- "сурт"
  SELECT Unicode::Fold("Eylül", "Turkish" AS Language); -- "eylul"
  ```
- `Unicode::ReplaceAll(input:Utf8{Flags:AutoMap}, find:Utf8, replacement:Utf8) -> Utf8`
- `Unicode::ReplaceFirst(input:Utf8{Flags:AutoMap}, find:Utf8, replacement:Utf8) -> Utf8`
- `Unicode::ReplaceLast(input:Utf8{Flags:AutoMap}, find:Utf8, replacement:Utf8) -> Utf8`

  Replaces all/first/last occurrences of the `find` string in the `input` with `replacement`.
- `Unicode::RemoveAll(input:Utf8{Flags:AutoMap}, symbols:Utf8) -> Utf8`
- `Unicode::RemoveFirst(input:Utf8{Flags:AutoMap}, symbols:Utf8) -> Utf8`
- `Unicode::RemoveLast(input:Utf8{Flags:AutoMap}, symbols:Utf8) -> Utf8`

  Deletes all/first/last occurrences of characters in the `symbols` set from the `input`. The second argument is interpreted as an unordered set of characters to be removed.

```
SELECT Unicode::ReplaceLast("absence", "enc", ""); -- "abse"
SELECT Unicode::RemoveAll("abandon", "an"); -- "bdo"
```

- `Unicode::ToCodePointList(Utf8{Flags:AutoMap}) -> List<Uint32>`

  Splits a string into a Unicode sequence of codepoints.
- `Unicode::FromCodePointList(List<Uint32>{Flags:AutoMap}) -> Utf8`

  Generates a Unicode string from codepoints.

```
SELECT Unicode::ToCodePointList("Щавель"); -- [1065, 1072, 1074, 1077, 1083, 1100]
SELECT Unicode::FromCodePointList(AsList(99,111,100,101,32,112,111,105,110,116,115,32,99,111,110,118,10
1,114,116,101,114)); -- "code points converter"
```

- `Unicode::Reverse(Utf8{Flags:AutoMap}) -> Utf8`

  Reverses a string.
- `Unicode::ToLower(Utf8{Flags:AutoMap}) -> Utf8`
- `Unicode::ToUpper(Utf8{Flags:AutoMap}) -> Utf8`
- `Unicode::ToTitle(Utf8{Flags:AutoMap}) -> Utf8`

  Converts a string to UPPER, lower, or Title case.
- `Unicode::SplitToList(string:Utf8?, separator:Utf8, [DelimeterString:Bool?, SkipEmpty:Bool?, Limit:Uint64?
  ]) -> List<Utf8>`

  Splits a string into substrings by separator.
  `string` -- Source string. `separator` -- Separator. Parameters:

  - DelimeterString:Bool? — treating a delimiter as a string (true, by default) or a set of characters "any of" (false)
  - SkipEmpty:Bool? - whether to skip empty strings in the result, is false by default
  - Limit:Uint64? - Limits the number of fetched components (unlimited by default); if the limit is exceeded, the raw suffix of the source string is returned in the last item
- `Unicode::JoinFromList(List<Utf8>{Flags:AutoMap}, separator:Utf8) -> Utf8`

  Concatenates a list of strings via a `separator` into a single string.

```
SELECT Unicode::SplitToList("One, two, three, four, five", ", ", 2 AS Limit); -- ["One", "two", "three,
four, five"]
SELECT Unicode::JoinFromList(["One", "two", "three", "four", "five"], ";"); -- "One;two;three;four;five"
```

- `Unicode::ToUint64(string:Utf8{Flags:AutoMap}, [prefix:Uint16?]) -> Uint64`

  Converts a string to a number.

  The second optional argument sets the number system. By default, 0 (automatic detection by prefix).
  Supported prefixes: `0x(0X)` - base-16, `0` - base-8. Defaults to base-10.
  The `-` sign before a number is interpreted as in C unsigned arithmetic. For example, `-0x1` -> UI64_MAX.
  If there are incorrect characters in a string or a number goes beyond ui64, the function terminates with an error.
- `Unicode::TryToUint64(string:Utf8{Flags:AutoMap}, [prefix:Uint16?]) -> Uint64?`

  Similar to the `Unicode::ToUint64()` function, except that it returns `NULL` instead of an error.

```
SELECT Unicode::ToUint64("77741"); -- 77741
SELECT Unicode::ToUint64("-77741"); -- 18446744073709473875
SELECT Unicode::TryToUint64("asdh831"); -- Null
```

Url

Normalize

- `Url::Normalize(String) -> String?`

Normalizes the URL in a robot-friendly way: converts the hostname into lowercase, strips out certain fragments, and so on.
The normalization result only depends on the URL itself. The normalization **DOES NOT** include operations depending on the external data: transformation based on duplicates, mirrors, etc.

Returned value:

- Normalized URL.
- `NULL`, if the passed string argument can't be parsed as a URL.

Examples

```
SELECT Url::Normalize("hTTp://wWw.yDb.TECH/"); -- "http://www.ydb.tech/"
SELECT Url::Normalize("http://ydb.tech#foo");      -- "http://ydb.tech/"
```

NormalizeWithDefaultHttpScheme

- `Url::NormalizeWithDefaultHttpScheme(String?) -> String?`

Normalizes similarly to `Url::Normalize`, but inserts the `http://` schema in case there is no schema.

Returned value:

- Normalized URL.
- Source URL, if the normalization has failed.

Examples

```
SELECT Url::NormalizeWithDefaultHttpScheme("wWw.yDb.TECH");    -- "http://www.ydb.tech/"
SELECT Url::NormalizeWithDefaultHttpScheme("http://ydb.tech#foo"); -- "http://ydb.tech/"
```

Encode / Decode

Encode a UTF-8 string to the urlencoded format (`Url::Encode`) and back (`Url::Decode`).

List of functions

- `Url::Encode(String?) -> String?`
- `Url::Decode(String?) -> String?`

Examples

```
SELECT Url::Decode("http://ydb.tech/%D1%81%D1%82%D1%80%D0%B0%D0%BD%D0%B8%D1%86%D0%B0");
  -- "http://ydb.tech/page"
SELECT Url::Encode("http://ydb.tech/page");
  -- "http://ydb.tech/%D1%81%D1%82%D1%80%D0%B0%D0%BD%D0%B8%D1%86%D0%B0"
```

Parse

Parses the URL into parts.

```
Url::Parse(Parse{Flags:AutoMap}) -> Struct< Frag: String?, Host: String?, ParseError: String?, Pass: String?,
Path: String?, Port: String?, Query: String?, Scheme: String?, User: String? >
```

Examples

```
SELECT Url::Parse(
  "https://en.wikipedia.org/wiki/Isambard_Kingdom_Brunel?s=24&g=h-24#Great_Western_Railway");
/*
(
  "Frag": "Great_Western_Railway",
  "Host": "en.wikipedia.org",
  "ParseError": null,
  "Pass": null,
  "Path": "/wiki/Isambard_Kingdom_Brunel",
  "Port": null,
  "Query": "s=24&g=h-24",
  "Scheme": "https",
  "User": null
)
*/
```

Get...

Get a component of the URL.

List of functions

- `Url::GetScheme(String{Flags:AutoMap}) -> String`
- `Url::GetHost(String?) -> String?`
- `Url::GetHostPort(String?) -> String?`

- `Url::GetSchemeHost(String?) -> String?`
- `Url::GetSchemeHostPort(String?) -> String?`
- `Url::GetPort(String?) -> String?`
- `Url::GetTail(String?) -> String?` -- everything following the host: path + query + fragment
- `Url::GetPath(String?) -> String?`
- `Url::GetFragment(String?) -> String?`
- `Url::GetCGIParam(String?, String) -> String?` -- The second parameter is the name of the intended CGI parameter.
- `Url::GetDomain(String?, Uint8) -> String?` -- The second parameter is the required domain level.
- `Url::GetTLD(String{Flags:AutoMap}) -> String`
- `Url::IsKnownTLD(String{Flags:AutoMap}) -> Bool` -- Registered on iana.org.
- `Url::IsWellKnownTLD(String{Flags:AutoMap}) -> Bool` -- Belongs to a small whitelist of com, net, org, ru, and so on.
- `Url::GetDomainLevel(String{Flags:AutoMap}) -> Uint64`
- `Url::GetSignificantDomain(String{Flags:AutoMap}, [List<String>?]) -> String`

  Returns a second-level domain in most cases and a third-level domain for the hostnames like: `***.XXX.YY`, where `XXX` is com, net, org, co, gov, or edu. You can redefine this list using an optional second argument
- `Url::GetOwner(String{Flags:AutoMap}) -> String`

  Returns the domain that's most likely owned by an individual or organization. Unlike `Url::GetSignificantDomain`, it uses a special whitelist. Besides the `***.co.uk` domains, it can return a third-level domain used by free hosting sites and blogs (for example: something.livejournal.com)

Examples

```
SELECT Url::GetScheme("https://ydb.tech");       -- "https://"
SELECT Url::GetDomain("http://www.ydb.tech", 2); -- "ydb.tech"
```

Cut...

- `Url::CutScheme(String?) -> String?`

  Returns the passed URL without the schema (`http://`, `https://`, etc.).
- `Url::CutWWW(String?) -> String?`

  Returns the passed domain without the "www." prefix (if any).
- `Url::CutWWW2(String?) -> String?`

  Returns the passed domain without the prefixes like "www.", "www2.", "wwww777." (if any).
- `Url::CutQueryStringAndFragment(String{Flags:AutoMap}) -> String`

  Returns a copy of the passed URL, stripping out all the CGI parameters and fragments ("?foo=bar" and/or "#baz").

Examples

```
SELECT Url::CutScheme("http://www.ydb.tech"); -- "www.ydb.tech"
SELECT Url::CutWWW("www.ydb.tech");           -- "ydb.tech"
```

...Punycode...

Punycode transformations.

List of functions

- `Url::HostNameToPunycode(String{Flag:AutoMap}) -> String?`
- `Url::ForceHostNameToPunycode(String{Flag:AutoMap}) -> String`
- `Url::PunycodeToHostName(String{Flag:AutoMap}) -> String?`
- `Url::ForcePunycodeToHostName(String{Flag:AutoMap}) -> String`
- `Url::CanBePunycodeHostName(String{Flag:AutoMap}) -> Bool`

Examples

```
SELECT Url::PunycodeToHostName("xn--80aniges7g.xn--j1aef"); -- "example.com"
```

...Query...

Query transformations.

List of functions

```
Url::QueryStringToList(String{Flag:AutoMap}, [
  KeepBlankValues:Bool?,  -- Empty values in percent-encoded queries are interpreted as empty strings, defaul
ts to false.
  Strict:Bool?,           -- If false, parsing errors are ignored and incorrect fields are skipped, defaults
to true.
  MaxFields:Uint32?,      -- The maximum number of fields. If exceeded, an exception is thrown. Defaults to M
ax<Uint32>.
  Separator:String?       -- A key-value pair separator, defaults to '&'.
]) -> List<Tuple<String, String>>
Url::QueryStringToDict(String{Flag:AutoMap}, [
  KeepBlankValues:Bool?,  -- Empty values in percent-encoded queries are interpreted as empty strings, defaul
ts to false.
  Strict:Bool?,           -- If false, parsing errors are ignored and incorrect fields are skipped, defaults
to true.
  MaxFields:Uint32?,      -- The maximum number of fields. If exceeded, an exception is thrown. Defaults to M
ax<Uint32>.
  Separator:String?       -- A key-value pair separator, defaults to '&'.
]) -> Dict<String, List<String>>
Url::BuildQueryString(Dict<String, List<String?>>{Flag:AutoMap}, [
  Separator:String?       -- A key-value pair separator, defaults to '&'.
]) -> String
Url::BuildQueryString(Dict<String, String?>{Flag:AutoMap}, [
  Separator:String?       -- A key-value pair separator, defaults to '&'.
]) -> String
Url::BuildQueryString(List<Tuple<String, String?>>{Flag:AutoMap}, [
  Separator:String?       -- A key-value pair separator, defaults to '&'.
]) -> String
```

Examples

```
SELECT Url::QueryStringToList("a=1&b=2&a=3");                      -- [("a", "1"), ("b", "2"), ("a", "3")]
SELECT Url::QueryStringToDict("a=1&b=2&a=3");                      -- {"b" : ["2"], "a" : ["1", "3"]}
SELECT Url::BuildQueryString([("a", "1"), ("a", "3"), ("b", "2")]); -- "a=1&a=3&b=2"
SELECT Url::BuildQueryString({"a" : "1", "b" : "2"});              -- "b=2&a=1"
SELECT Url::BuildQueryString({"a" : ["1", "3"], "b" : ["2", "4"]}); -- "b=2&b=4&a=1&a=3"
```

Yson

YSON is a JSON-like data format developed at Yandex.

- Similarities with JSON:
  - Does not have a strict scheme.
  - Besides simple data types, it supports dictionaries and lists in arbitrary combinations.
- Some differences from JSON:
  - It also has a binary representation in addition to the text representation.
  - The text representation uses semicolons instead of commas and equal signs instead of colons.
- The concept of "attributes" is supported, that is, named properties that can be assigned to a node in the tree.

Implementation specifics and functionality of the module:

- Along with YSON, this module also supports standard JSON to expand the application scope in a way.
- It works with a DOM representation of YSON in memory that in YQL terms is passed between functions as a "resource" (see the description of special data types). Most of the module's functions have the semantics of a query to perform a specified operation with a resource and return an empty optional type if the operation failed because the actual data type mismatched the expected one.
- Provides several main classes of functions (find below a complete list and detailed description of functions):
  - `Yson::Parse***`: Getting a resource with a DOM object from serialized data, with all further operations performed on the obtained resource.
  - `Yson::From`: Getting a resource with a DOM object from simple YQL data types or containers (lists or dictionaries).
  - `Yson::ConvertTo***`: Converting a resource to primitive data types or containers.
  - `Yson::Lookup***`: Getting a single list item or a dictionary with optional conversion to the relevant data type.
  - `Yson::YPath***`: Getting one element from the document tree based on the relative path specified, optionally converting it to the relevant data type.
  - `Yson::Serialize***`: Getting a copy of data from the resource and serializing the data in one of the formats.
- For convenience, when serialized Yson and Json are passed to functions expecting a resource with a DOM object, implicit conversion using `Yson::Parse` or `Yson::ParseJson` is done automatically. In SQL syntax, the dot or square brackets operator automatically adds a `Yson::Lookup` call. To serialize a resource, you still need to call `Yson::ConvertTo***` or `Yson::Serialize***`. It means that, for example, to get the "foo" element as a string from the Yson column named mycolumn and serialized as a dictionary, you can write: `SELECT Yson::ConvertToString(mycolumn["foo"]) FROM mytable;` or `SELECT Yson::ConvertToString(mycolumn.foo) FROM mytable;`. In the variant with a dot, special characters can be escaped by general rules for IDs.

The module's functions must be considered as "building blocks" from which you can assemble different structures, for example:

- `Yson::Parse*** -> Yson::Serialize***`: Converting from one format to other.
- `Yson::Parse*** -> Yson::Lookup -> Yson::Serialize***`: Extracting the value of the specified subtree in the source YSON tree.
- `Yson::Parse*** -> Yson::ConvertToList -> ListMap -> Yson::Lookup***`: Extracting items by a key from the YSON list.

Examples

```
$node = Json(@@
  {"abc": {"def": 123, "ghi": "hello"}}
@@);
SELECT Yson::SerializeText($node.abc) AS `yson`;
-- {"def"=123;"ghi"="\xD0\xBF\xD1\x80\xD0\xB8\xD0\xB2\xD0\xB5\xD1\x82"}
```

```
$node = Yson(@@
  <a=z;x=y>[
    {abc=123; def=456};
    {abc=234; xyz=789};
  ]
@@);
$attrs = Yson::YPath($node, "/@");

SELECT
  ListMap(Yson::ConvertToList($node), ($x) -> { return Yson::LookupInt64($x, "abc") }) AS abcs,
  Yson::ConvertToStringDict($attrs) AS attrs,
  Yson::SerializePretty(Yson::Lookup($node, "7", Yson::Options(false AS Strict))) AS miss;

/*
- abcs: `[123; 234]`
- attrs: `{"a"="z";"x"="y"}`
- miss: `NULL`
*/
```

Yson::Parse...

```
Yson::Parse(Yson{Flags:AutoMap}) -> Resource<'Yson2.Node'>
Yson::ParseJson(Json{Flags:AutoMap}) -> Resource<'Yson2.Node'>
Yson::ParseJsonDecodeUtf8(Json{Flags:AutoMap}) -> Resource<'Yson2.Node'>

Yson::Parse(String{Flags:AutoMap}) -> Resource<'Yson2.Node'>? -- accepts YSON in any format
Yson::ParseJson(String{Flags:AutoMap}) -> Resource<'Yson2.Node'>?
Yson::ParseJsonDecodeUtf8(String{Flags:AutoMap}) -> Resource<'Yson2.Node'>?
```

The result of all three functions is non-serializable: it can only be passed as the input to other function from the Yson library. However, you can't save it to a table or return to the client as a result of the operation: such an attempt results in a typing error. You also can't return it outside subqueries: if you need to do this, call Yson::Serialize, and the optimizer will remove unnecessary serialization and

deserialization if materialization isn't needed in the end.

> **Note**
>
> The `Yson::ParseJsonDecodeUtf8` expects that characters outside the ASCII range must be additionally escaped.

Yson::From

```
Yson::From(T) -> Resource<'Yson2.Node'>
```

`Yson::From` is a polymorphic function that converts most primitive data types and containers (lists, dictionaries, tuples, structures, and so on) into a Yson resource. The source object type must be Yson-compatible. For example, in dictionary keys, you can only use the `String` or `Utf8` data types, but not `String?` or `Utf8?` .

Example

```
SELECT Yson::Serialize(Yson::From(TableRow())) FROM table1;
```

Yson::WithAttributes

```
Yson::WithAttributes(Resource<'Yson2.Node'>{Flags:AutoMap}, Resource<'Yson2.Node'>{Flags:AutoMap}) -> Resourc
e<'Yson2.Node'>?
```

Adds attributes (the second argument) to the Yson node (the first argument). The attributes must constitute a map node.

Yson::Equals

```
Yson::Equals(Resource<'Yson2.Node'>{Flags:AutoMap}, Resource<'Yson2.Node'>{Flags:AutoMap}) -> Bool
```

Checking trees in memory for equality. The operation is tolerant to the source serialization format and the order of keys in dictionaries.

Yson::GetHash

```
Yson::GetHash(Resource<'Yson2.Node'>{Flags:AutoMap}) -> Uint64
```

Calculating a 64-bit hash from an object tree.

Yson::Is...

```
Yson::IsEntity(Resource<'Yson2.Node'>{Flags:AutoMap}) -> bool
Yson::IsString(Resource<'Yson2.Node'>{Flags:AutoMap}) -> bool
Yson::IsDouble(Resource<'Yson2.Node'>{Flags:AutoMap}) -> bool
Yson::IsUint64(Resource<'Yson2.Node'>{Flags:AutoMap}) -> bool
Yson::IsInt64(Resource<'Yson2.Node'>{Flags:AutoMap}) -> bool
Yson::IsBool(Resource<'Yson2.Node'>{Flags:AutoMap}) -> bool
Yson::IsList(Resource<'Yson2.Node'>{Flags:AutoMap}) -> bool
Yson::IsDict(Resource<'Yson2.Node'>{Flags:AutoMap}) -> bool
```

Checking that the current node has the appropriate type. The Entity is `#`.

Yson::GetLength

```
Yson::GetLength(Resource<'Yson2.Node'>{Flags:AutoMap}) -> Uint64?
```

Getting the number of elements in a list or dictionary.

Yson::ConvertTo...

```
Yson::ConvertTo(Resource<'Yson2.Node'>{Flags:AutoMap}, Type<T>) -> T
Yson::ConvertToBool(Resource<'Yson2.Node'>{Flags:AutoMap}) -> Bool?
Yson::ConvertToInt64(Resource<'Yson2.Node'>{Flags:AutoMap}) -> Int64?
Yson::ConvertToUint64(Resource<'Yson2.Node'>{Flags:AutoMap}) -> Uint64?
Yson::ConvertToDouble(Resource<'Yson2.Node'>{Flags:AutoMap}) -> Double?
Yson::ConvertToString(Resource<'Yson2.Node'>{Flags:AutoMap}) -> String?
Yson::ConvertToList(Resource<'Yson2.Node'>{Flags:AutoMap}) -> List<Resource<'Yson2.Node'>>
Yson::ConvertToBoolList(Resource<'Yson2.Node'>{Flags:AutoMap}) -> List<Bool>
Yson::ConvertToInt64List(Resource<'Yson2.Node'>{Flags:AutoMap}) -> List<Int64>
Yson::ConvertToUint64List(Resource<'Yson2.Node'>{Flags:AutoMap}) -> List<Uint64>
Yson::ConvertToDoubleList(Resource<'Yson2.Node'>{Flags:AutoMap}) -> List<Double>
Yson::ConvertToStringList(Resource<'Yson2.Node'>{Flags:AutoMap}) -> List<String>
Yson::ConvertToDict(Resource<'Yson2.Node'>{Flags:AutoMap}) -> Dict<String,Resource<'Yson2.Node'>>
Yson::ConvertToBoolDict(Resource<'Yson2.Node'>{Flags:AutoMap}) -> Dict<String,Bool>
Yson::ConvertToInt64Dict(Resource<'Yson2.Node'>{Flags:AutoMap}) -> Dict<String,Int64>
Yson::ConvertToUint64Dict(Resource<'Yson2.Node'>{Flags:AutoMap}) -> Dict<String,Uint64>
Yson::ConvertToDoubleDict(Resource<'Yson2.Node'>{Flags:AutoMap}) -> Dict<String,Double>
Yson::ConvertToStringDict(Resource<'Yson2.Node'>{Flags:AutoMap}) -> Dict<String,String>
```

Warning

These functions do not do implicit type casting by default, that is, the value in the argument must exactly match the function called.

`Yson::ConvertTo` is a polymorphic function that converts the data type that is specified in the second argument and supports containers (lists, dictionaries, tuples, structures, and so on) into a Yson resource.

Example

```
$data = Yson(@@{
    "name" = "Anya";
    "age" = 15u;
    "params" = {
        "ip" = "95.106.17.32";
        "last_time_on_site" = 0.5;
        "region" = 213;
        "user_agent" = "Mozilla/5.0"
    }
}@@);
SELECT Yson::ConvertTo($data,
    Struct<
        name: String,
        age: Uint32,
        params: Dict<String,Yson>
    >
);
```

Yson::Contains

```
Yson::Contains(Resource<'Yson2.Node'>{Flags:AutoMap}, String) -> Bool?
```

Checks for a key in the dictionary. If the object type is a map, then it searches among the keys.
If the object type is a list, then the key must be a decimal number, i.e., an index in the list.

Yson::Lookup...

```
Yson::Lookup(Resource<'Yson2.Node'>{Flags:AutoMap}, String) -> Resource<'Yson2.Node'>?
Yson::LookupBool(Resource<'Yson2.Node'>{Flags:AutoMap}, String) -> Bool?
Yson::LookupInt64(Resource<'Yson2.Node'>{Flags:AutoMap}, String) -> Int64?
Yson::LookupUint64(Resource<'Yson2.Node'>{Flags:AutoMap}, String) -> Uint64?
Yson::LookupDouble(Resource<'Yson2.Node'>{Flags:AutoMap}, String) -> Double?
Yson::LookupString(Resource<'Yson2.Node'>{Flags:AutoMap}, String) -> String?
Yson::LookupDict(Resource<'Yson2.Node'>{Flags:AutoMap}, String) -> Dict<String,Resource<'Yson2.Node'>>?
Yson::LookupList(Resource<'Yson2.Node'>{Flags:AutoMap}, String) -> List<Resource<'Yson2.Node'>>?
```

The above functions are short notations for a typical use case: `Yson::YPath`: go to a level in the dictionary and then extract the value — `Yson::ConvertTo***`. For all the listed functions, the second argument is a key name from the dictionary (unlike YPath, it has no `/` prefix) or an index from the list (for example, `7`). They simplify the query and produce a small gain in speed.

Yson::YPath

```
Yson::YPath(Resource<'Yson2.Node'>{Flags:AutoMap}, String) -> Resource<'Yson2.Node'>?
Yson::YPathBool(Resource<'Yson2.Node'>{Flags:AutoMap}, String) -> Bool?
Yson::YPathInt64(Resource<'Yson2.Node'>{Flags:AutoMap}, String) -> Int64?
Yson::YPathUint64(Resource<'Yson2.Node'>{Flags:AutoMap}, String) -> Uint64?
Yson::YPathDouble(Resource<'Yson2.Node'>{Flags:AutoMap}, String) -> Double?
Yson::YPathString(Resource<'Yson2.Node'>{Flags:AutoMap}, String) -> String?
Yson::YPathDict(Resource<'Yson2.Node'>{Flags:AutoMap}, String) -> Dict<String,Resource<'Yson2.Node'>>?
Yson::YPathList(Resource<'Yson2.Node'>{Flags:AutoMap}, String) -> List<Resource<'Yson2.Node'>>?
```

Lets you get a part of the resource based on the source resource and the part's path in YPath format.

Yson::Attributes

```
Yson::Attributes(Resource<'Yson2.Node'>{Flags:AutoMap}) -> Dict<String,Resource<'Yson2.Node'>>
```

Getting all node attributes as a dictionary.

Yson::Serialize...

```
Yson::Serialize(Resource<'Yson2.Node'>{Flags:AutoMap}) -> Yson -- A binary representation
Yson::SerializeText(Resource<'Yson2.Node'>{Flags:AutoMap}) -> Yson
Yson::SerializePretty(Resource<'Yson2.Node'>{Flags:AutoMap}) -> Yson -- To get a text result, wrap it in ToBy
tes(...)
```

Yson::SerializeJson

```
Yson::SerializeJson(Resource<'Yson2.Node'>{Flags:AutoMap}, [Resource<'Yson2.Options'>?, SkipMapEntity:Bool?,
EncodeUtf8:Bool?, WriteNanAsString:Bool?]) -> Json?
```

- `SkipMapEntity` serializes `#` values in dictionaries. The value of attributes is not affected by the flag. By default, `false`.

- `EncodeUtf8` responsible for escaping non-ASCII characters. By default, `false`.
- `WriteNanAsString` allows serializing `NaN` and `Inf` values as strings. By default, `false`.

The `Yson` and `Json` data types returned by serialization functions are special cases of a string that is known to contain data in the given format (Yson/Json).

Yson::Options

```
Yson::Options([AutoConvert:Bool?, Strict:Bool?]) -> Resource<'Yson2.Options'>
```

It's passed in the last optional argument (omitted for brevity) to the methods `Parse...`, `ConvertTo...`, `Contains`, `Lookup...`, and `YPath...` that accept the result of the `Yson::Options` call. By default, all the `Yson::Options` fields are false and when enabled (true), they modify the behavior as follows:

- **AutoConvert**: If the value passed to Yson doesn't match the result data type exactly, the value is converted where possible. For example, `Yson::ConvertToInt64` in this mode will convert even Double numbers to Int64.
- **Strict**: By default, all functions from the Yson library return an error in case of issues during query execution (for example, an attempt to parse a string that is not Yson/Json, or an attempt to search by a key in a scalar type, or when a conversion to an incompatible data type has been requested, and so on). If you disable the strict mode, `NULL` is returned instead of an error in most cases. When converting to a dictionary or list (`ConvertTo<Type>Dict` or `ConvertTo<Type>List`), improper items are excluded from the resulting collection.

Example

```
$yson = @@{y = true; x = 5.5}@@y;
SELECT Yson::LookupBool($yson, "z"); --- null
SELECT Yson::LookupBool($yson, "y"); --- true

SELECT Yson::LookupInt64($yson, "x"); --- Error
SELECT Yson::LookupInt64($yson, "x", Yson::Options(false as Strict)); --- null
SELECT Yson::LookupInt64($yson, "x", Yson::Options(true as AutoConvert)); --- 5

SELECT Yson::ConvertToBoolDict($yson); --- Error
SELECT Yson::ConvertToBoolDict($yson, Yson::Options(false as Strict)); --- { "y": true }
SELECT Yson::ConvertToDoubleDict($yson, Yson::Options(false as Strict)); --- { "x": 5.5 }
```

If you need to use the same Yson library settings throughout the query, it's more convenient to use PRAGMA yson.AutoConvert; and/or PRAGMA yson.Strict;. Only with these `PRAGMA` you can affect implicit calls to the Yson library occurring when you work with Yson/Json data types.

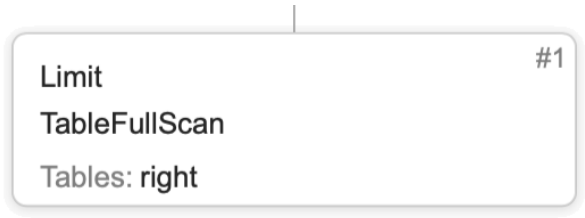
Query plan structure

To understand how a query will be executed, you can build and analyze its plan. The query plan structure in YDB is represented as a graph, where each node contains information about operations and tables.



Below, you can find information about node types, and an example of analyzing a specific query plan can be found here.

Node types

Stage

Query execution stage.

UI representation

A stage can contain the following operations:

TableFullScan

Full table scan. This operation's resource consumption is proportional to the table size, so it should be avoided whenever possible.

Attribute	Description
Table	table name
ReadColumns	read columns list
ReadLimit	read rows limit
Reverse	flag indicating the order in which the rows will be read, by default the order is forward (ascending), but if the flag is set to `true`, the reading order will be reversed (descending).
Parallel	flag indicating that rows will be read from shards in parallel

TableRangeScan

Reading a table by a specific primary key range.

Attribute	Description
Table	table name
ReadColumns	read columns list
ReadRange	key range
ReadLimit	read rows limit
Reverse	flag indicating the order in which the rows will be read, by default the order is forward (ascending), but if the flag is set to `true`, the reading order will be reversed (descending).
Parallel	flag indicating that rows will be read from shards in parallel

TablePointLookup

Reading a table by specific primary key values. Note that for this operation, all components of the primary key should be specified. Reading by a key prefix is performed as a `TableRangeScan` operation.

Attribute	Description
Table	table name
ReadColumns	read columns list

Upsert

Updates or inserts multiple rows to a table based on a comparison by the primary key. The values of the specified columns are updated for the existing rows, but the values of the other columns are preserved.

Attribute	Description
Table	table name
Columns	columns contained in the row

Delete

Deleting rows from the table.

Attribute	Description
Table	table name

Join

Combine two data sources (subqueries or tables) by keys. The join strategy is specified in the operation description.

Filter

Filtering rows, keeping only those for which a predicate returns `true`.

Attribute	Description
Predicate	filtering condition
Limit	rows limit

Aggregate

Grouping rows by the values of the specified columns or expressions.

Attribute	Description
GroupBy	columns or expressions used for aggregation
Aggregation	aggregate function

Sort

Sorting rows.

Attribute	Description
SortBy	columns or expressions used for sorting

TopSort

Partial rows sorting with a specified limit.

Attribute	Description
TopSortBy	columns or expressions used for sorting
Limit	rows limit

Top

Returns the first N elements that are less or equal to the N+1 element if the entire sequence were sorted.

Attribute	Description
TopBy	columns or expressions by which the first N rows will be taken
Limit	rows limit

Limit

Limit on the number of rows.

Attribute	Description
Limit	limit value

Offset

Offset, allowing to skip the first N elements of a given set of rows.

Attribute	Description
Offset	offset value

Union

Concatenate the results of two or more subqueries into a single row set.

Iterator

Iterates through a given set of rows. Typically uses a precompute as an argument.

PartitionByKey

Partitioning by key. Typically uses a precompute.

Connection

Data dependencies between stages.

UI representation

Each stage is executed as a certain number of tasks. For example, a reading stage may be executed in N tasks, where N is the number of table shards. The method of transferring data between stages depends on the type of connection. Below is a description of different connections.

UnionAll

Combines the results of all producer stage tasks and sends them as a single result to a single consumer stage task.

Merge

This is a special case of `UnionAll`. The results of the producer stage are sorted by a specified set of columns and merged into a result that is also sorted.

Broadcast

Sends the result of a single producer stage task to all consumer stage tasks.

Map

Implements 1-to-1 relationships between tasks of stages, the producer and consumer stages should have the same number of tasks.

HashShuffle

Sends the results of producer stage tasks to consumer stage tasks based on a certain rule for specified columns. The rule is defined in the code, but the list of columns is specified in the connection.

ResultSet

The query execution result.

UI representation

Precompute

Materialized intermediate result.

UI representation

Stages that depend on precomputes should be executed after the precompute has been completed.

Using YDB UI

YDB provides tools for monitoring and determining system health:

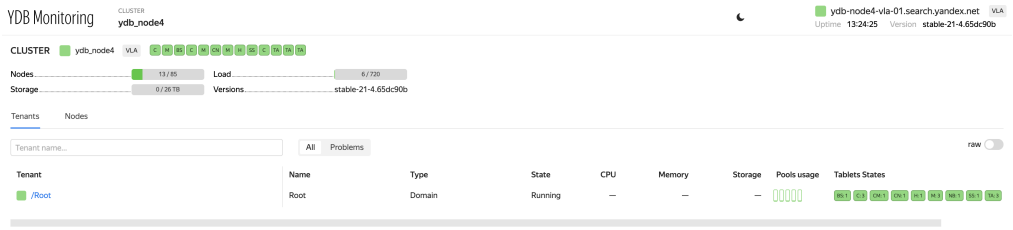
- YDB Monitoring: The main monitor of the cluster. It shows the health of nodes and storage groups.
- Interconnect overview: The state of cluster interconnects.
- Logs: Each YDB component writes messages to logs of different levels. They can be used to detect severe issues or identify the root causes of issues.
- Charts: YDB collects a range of metrics that can be used to determine the health of the entire system or of a specific component.

Using YDB UI

YDB provides tools for monitoring and determining system health:

- YDB Monitoring: The main monitor of the cluster. It shows the health of nodes and storage groups.
- Interconnect overview: The state of cluster interconnects.
- Logs: Each YDB component writes messages to logs of different levels. They can be used to detect severe issues or identify the root causes of issues.
- Charts: YDB collects a range of metrics that can be used to determine the health of the entire system or of a specific component.

YDB Monitoring



YDB Monitoring is a set of web pages that display the system health according to a range of different aspects. The pages contain lists of components and their current parameters. Many components have a health color indicator before the name.

Home page

The page is available at:

```
http://<endpoint>:8765/monitoring/cluster
```

An example of the page layout is shown in the screenshot below.

In the upper-right corner of the page, you can see details about the node that created the current page:

- host.
- node uptime.
- ydb version run by the node.

Below is the cluster summary:

- cluster name, list of running tablets.
- **Nodes**: The number of nodes.
- **Load**: The total CPU utilization level on all nodes.
- **Storage**: The used/total storage space.
- **Versions**: The list of YDB versions run on the cluster nodes.

Next, you will find lists of tenants and nodes on the Tenants and Nodes tabs, respectively.

Tenant list

YDB is a multi-tenant DBMS that lets you execute isolated queries against databases of different users called tenants. Each database belongs to one tenant.

The tenants list contains the following information on each tenant:

- **Tenant**: Tenant path.
- **Name**: Tenant name.
- **Type**: Tenant type.
- **State**: Tenant health.
- **CPU**: CPU utilization by the tenant's nodes.
- **Memory**: RAM consumption by the tenant's nodes.
- **Storage**: Estimated amount of data stored by the tenant.
- **Pools usage**: CPU usage by the nodes broken down by the internal stream pools.
- **Tablets States**: Tablets running in the given tenant.

`Domain` type tenants serve the system components needed to ensure all tenants can operate. This includes all storage nodes and system tablets. `Dedicated` type tenants perform database maintenance.

If you click on the tenant's path, you can go to the tenant page.

Node list

The list includes all nodes in the cluster. For each node, you can see:

- #: Node ID.
- **Host**: The host running the node.
- **Endpoints**: The ports being listened to.
- **Version**: The YDB version being run.
- **Uptime**: The node uptime.
- **Memory used**: The amount of RAM used.
- **Memory limit**: The RAM utilization limit set via cgroup.
- **Pools usage**: CPU utilization broken down by the internal stream pools.
- **Load average**: The average CPU utilization on the host.

To open the node page, click the host name.

Node page

The page is available at:

```
http://<endpoint>:8765/monitoring/node/<node-id>/
```

Information about the node is presented in the following sections:

- **Pools**: CPU utilization broken down by the internal stream pools, with roughly the following pool functions:

    - **System**: The tasks of critical system components.
    - **User**: User tasks, queries executed by tablets.
    - **Batch**: Long-running background tasks.
    - **IO**: Blocking I/O operations.
    - **IC**: Networking operations.

  High pool utilization might degrade performance and increase the system response time.
- **Common info**: Basic information about the node:
    - **Version**: The YDB version.
    - **Uptime**: The node uptime.
    - **DC**: The availability zone where the node resides.
    - **Rack**: The ID of the rack where the node resides.
- **Load average**: Average host CPU utilization for different time intervals:
    - 1 minute.
    - 5 minutes.
    - 15 minutes.

The node page has the Storage and Tablets tabs with a list of storage groups and a list of tablets, respectively.

List of storage groups on the node

For storage nodes, the list includes storage groups that store data on this node's disk. For dynamic nodes, the list shows the storage groups of the tenant that the node belongs to.

Storage groups are grouped by storage pools. Each pool can be expanded into a list of groups.

For each group, the following information is provided:

- The ID of the storage group.
- The performance indicator of the group.
- The number of VDisks in the group.
- The data storage topology.

Each storage group can also be expanded into a list of VDisks, with the following information provided for each VDisk:

- VDiskID.
- The unique (within the node) PDiskID where the VDisk resides.
- The ID of the node where the VDisk resides.
- Free/available space on the block store volume.
- Path used to access block storage.

This list can be used to identify storage groups that were affected by disk or node failure.

List of tablets residing on the node

Many YDB components are implemented as tablets. The system can move tablets between nodes. A certain number of tablets can be run on any node.

In the upper part of the list of tablets, there's a big indicator for tablets running on the given node. It shows the ratio of fully launched and running tablets.

Under the indicator, you can see a list of tablets, where each tablet is shown as a small color indicator icon. When you hover over the indicator, the tablet summary is shown:

- **Tablet**: The ID of the tablet.
- **NodeID**: The ID of the node where the tablet resides.
- **State**: The state of the tablet.
- **Type**: The type of tablet.
- **Uptime**: The uptime since the tablet was last launched.
- **Generation**: The tablet's generation (the number of the current launch attempt).

Tenant page

```
http://<endpoint>:8765/monitoring/tenant/healthcheck?name=<tenant-path>
```

Like the previous pages, this page includes the tenant summary, but unlike the other pages, this section is initially collapsed.

In the `Tenant Info` section, you can see the following information:

- **Pools**: Total CPU utilization by the tenant nodes broken down by internal stream pools (for more information about pools, see the tenant page).
- **Metrics**: Data about tablet utilization for this tenant:
    - **Memory**: The RAM utilized by tablets.
    - **CPU**: CPU utilized by tablets.
    - **Storage**: The amount of data stored by tablets.
    - **Network**: The estimated amount of data transferred between nodes.
    - **Read throughput**: The read stream created by the tenant's tablets.
    - **Write throughput**: The write stream created by the tenant's tablets.
- **Tablets/running**: The number of running tablets.

The tenant page also includes the following tabs:

- **HealthCheck**: The report regarding cluster issues, if any.
- **Storage**: List of storage groups showing the nodes and block store volumes hosting each VDisk.
- **Compute**: List of nodes showing the nodes and tablets running on them.

- **Schema**: Tenant schema that enables you to view tables, execute YQL queries, view a list of the slowest queries and the most loaded shards.
- **Network**: Cluster network health.

List of storage groups in the tenant

Similarly to the list of groups in the node, this page shows a list of storage groups in the given tenant. Storage groups are grouped by storage pools in the list. Each pool can be expanded into a list of groups.

List of nodes belonging to the tenant

Here you can see a list of nodes belonging to the current tenant. If the tenant has the domain type, the list includes storage nodes.

Each node is represented by the following parameters:

- #: Node ID.
- **Host**: The host running the node.
- **Uptime**: The node uptime.
- **Endpoints**: The ports being listened to.
- **Version**: The YDB version being run.
- **Pools usage**: CPU utilization broken down by the internal stream pools.
- **CPU**: CPU utilization by tablets.
- **Memory**: RAM consumption by tablets.
- **Network**: Network usage by tablets.
- **Tablets**: A list of tablets running on the node, grouped by type.

Tenant schema

The left part of the page shows a diagram of tenant objects where you can select specific tables and view their details.

The right part includes the tabs:

- **Info**: Information about the table and its schema.
- **Preview**: A preview of the first items in the table.
- **Graph**: A range of built-in graphs with information about the table status.
- **Describe**: The result of running the describe command.
- **Query**: The form for executing YQL queries.
- **Tablets**: The list of tablets serving the table.
- **ACL**: The Access Control List.
- **Top queries**: The top most time-consuming queries to the table.
- **Top shards**: The top most loaded table shards.

Network health

On the left side of the page, you can see the tenant's nodes as squares of health indicators.

Whenever you select a node, the right side of the screen shows details about the health of the network connection between this node and other nodes.

Whenever you select the ID and Racks checkboxes, you can also see the IDs of nodes and their location in racks.

Monitoring static groups

To perform a health check on a static group, go to the **Storage** panel. By default, it shows a list of groups with issues.

Enter `static` in the search bar. If the result is empty, no issues have been found for the static group. But if the panel shows a **static** group, check the VDisk health status in it. Acceptable health indicators are green (no issues) and blue (VDisk replication is in progress). Red indicator signals of an issue. Hover over the indicator to get a text description of the issue.

Health indicators

To the left of a component name, you might see a color indicating its health status.

The indicator colors have the following meaning:

- **Green**: There are no problems, the component is working normally.
- **Blue**: Data replication is in progress, no other issues observed.
- **Yellow**: There might be problems, the component is still running.
- **Red**: There are critical problems, the component is down (or runs with limitations).

If a component includes other components, then in the absence of its own issues, the state is determined by aggregating the states of its parts.

Hive web-viewer

The Hive web-viewer provides an interface for working with Hive.
Hive can be shared by a cluster or be tenant.
You can go to the Hive web-viewer from the YDB Monitoring.

Home page

The home page provides information about the distribution and usage of resources by tablets on each node in the form of a table.

The table is preceded by the following brief information:

- **Tenant**: The tenant that Hive is responsible for.
- **Tablets**: The percentage of tablets started and the number of running tablets to their total number.
- **Boot Queue**: The number of tablets in the boot queue.
- **Wait Queue**: The number of tablets that can't be started.
- **Resource Total**: Resource utilization by tablets (cpu, net).
- **Resource StDev**: Standard deviation of resource utilization (cnt, cpu, mem, net).

Then there is a table where each row represents a node managed by Hive. It has the following columns:

- **Node**: The node number.
- **Name**: The node FQDN and ic-port.
- **DC**: The datacenter where the node resides.
- **Domain**: The node tenant.
- **Uptime**: The node uptime.
- **Unknown**: The number of tablets whose state is unknown.
- **Starting**: The number of tablets being started.
- **Running**: The number of tablets running.
- **Types**: Tablet distribution by type.
- **Usage**: A normalized dominant resource.
- **Resources**:
  - **cnt**: The number of tablets that are not using any resources.
  - **cpu**: CPU usage by tablets.
  - **mem**: RAM usage by tablets.
  - **net**: Bandwidth usage by tablets.
- **Active**: Enables/disables the node to move tablets to this node.
- **Freeze**: Disables tablets to be deployed on other nodes.
- **Kick**: Moves all tablets from the node at once.
- **Drain**: Smoothly moves all tablets from the node.

Additional pages are presented below the table:

- **Bad tablets**: A list of tablets having issues or errors.
- **Heavy tablets**: A list of tablets utilizing a lot of resources.
- **Waiting tablets**: A list of tablets that can't be started.
- **Resources**: Resource utilization by each tablet.
- **Tenants**: A list of tenants indicating their local Hive tablets.
- **Nodes**: A list of nodes.
- **Storage**: A list of storage group pools.
- **Groups**: A list of storage groups for each tablet.
- **Settings**: The Hive configuration page.
- **Reassign Groups**: The page for reassigning storage groups across tablets.

You can also view what tablets use a particular group and, vice versa, what groups are used on a particular tablet.

Settings

The **Settings** page lists Hive configuration options that you can edit through the web-viewer.

Reassign Groups

Click **Reassign Groups** to open the window with parameters for balancing:

- **Storage pool**: Pool of storage groups for balancing.
- **Storage group**: If the previous item is not specified, you can specify only one group separately.
- **Type**: Type of tablets that balancing will be performed for.
- **Channels**: Range of channels that balancing will be performed for.
- **Percent**: Percentage of the total number of tablet channels that will be moved as a result of balancing.
- **Inflight**: The number of tablets being moved to other groups at the same time.

After specifying all the parameters, click "Query" to get the number of channels moved and unlock the "Reassign" button.
Clicking this button starts reassigning.

Interconnect Overview

Overview of cluster node interconnects. Available at:

```
http://<endpoint>:8765/actors/interconnect/overview
```

Shows, for every other node:

- ping
- system clock difference
- connection availability
- last written error

Logs

Logging levels

Level	Numeric value	Value
TRACE	8	Very detailed debugging information.
DEBUG	7	Debugging information for developers.
INFO	6	Debugging information for collecting statistics.
NOTICE	5	An event essential for the system or the user has occurred.
WARN	4	This is a warning, it should be responded to and fixed unless it's temporary.
ERROR	3	A non-critical error.
CRIT	2	A critical state.
ALERT	1	System degradation is possible, system components may fail.
EMERG	0	System outage (for example, cluster failure) is possible.

The logging level for different YDB components can be configured individually. For each component, either an explicitly set value or a default logging level value can be applied. The default logging level value can also be changed.

Changing the logging level

To change the logging level:

1. Follow the link in the format

   ```
   http://<endpoint>:8765/cms
   ```

   The `Cluster Management System` page opens.
2. On the **Configs** tab, click on the `LogConfigItems` line. The `Create new item` button will show up along with a list of already created configuration elements.
3. Click `Create new item` to create a new configuration item (or click the pencil button to edit a previously created item).
4. To change the default logging level, select the desired logging level from the `Level` drop-down list under `Default log settings`. The default global setting is `NOTICE`.
5. To change the logging level for individual components, use the table under `Component log settings`. In the line with the name of the component whose logging level you want to change, in the `Component` column, select the desired logging level from the drop-down list in the `Log level` column.
6. To save changes, click `Submit`

Charts

To view charts, use Grafana.

The main metrics of the system are displayed on the dashboard:

- **CPU Usage**: The total CPU utilization on all nodes (1 000 000 = 1 CPU).
- **Memory Usage**: RAM utilization by nodes.
- **Disk Space Usage**: Disk space utilization by nodes.
- **SelfPing**: The highest actual delivery time of deferred messages in the actor system over the measurement interval. Measured for messages with a 10 ms delivery delay. If this value grows, it might indicate microbursts of workload, high CPU utilization, or displacement of the YDB process from CPU cores by other processes.

Integrations YDB

This section provides the main information about YDB integrations with third-party systems.

> **Note**
>
> In addition to its own native protocol, YDB has a compatibility layer that allows external systems to connect to databases via the Apache Kafka network protocol. Due to the compatibility layer, many tools designed to work with Kafka can also interact with YDB. The compatibility level of each specific application needs to be clarified separately.

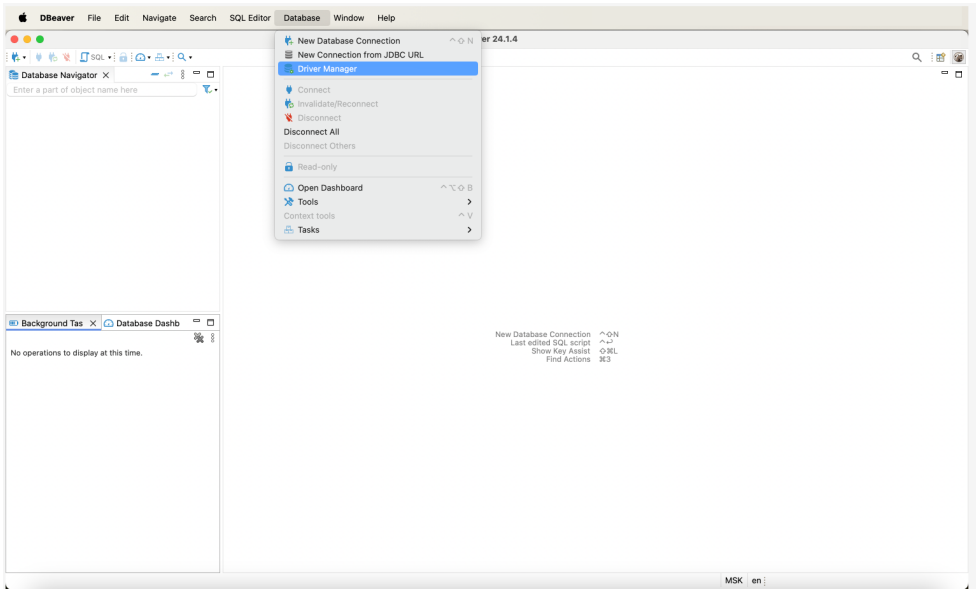
Connecting to YDB with DBeaver

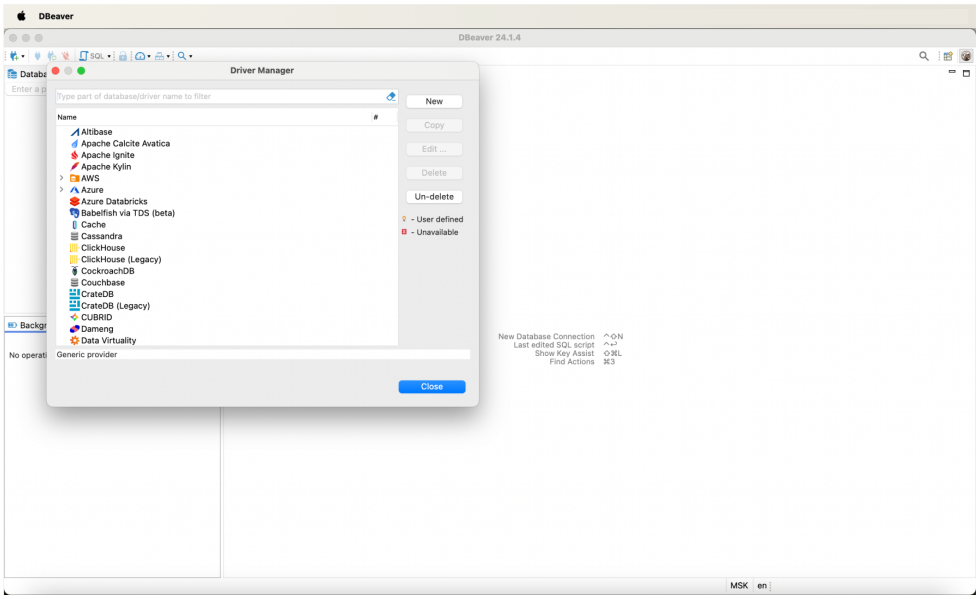
DBeaver is a free, cross-platform, open-source database management tool that provides a visual interface for connecting to various databases and executing SQL queries. It supports many database management systems, including MySQL, PostgreSQL, Oracle, and SQLite.

DBeaver allows you to work with YDB using the Java DataBase Connectivity (JDBC) protocol. This article demonstrates how to set up this integration.



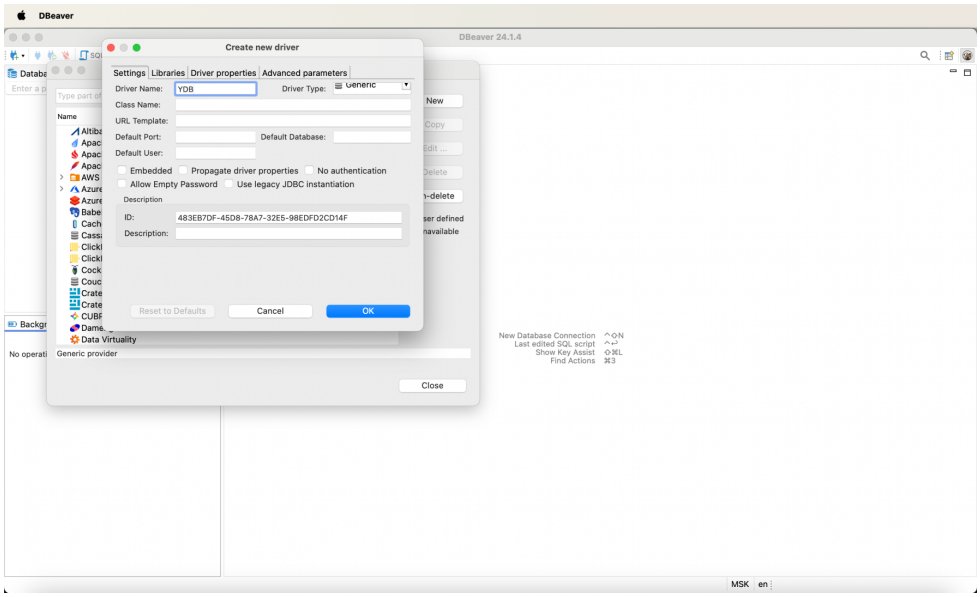
Connecting the YDB JDBC Driver to DBeaver

To connect to YDB from DBeaver, you will need the JDBC driver. Follow these steps to download the JDBC driver:

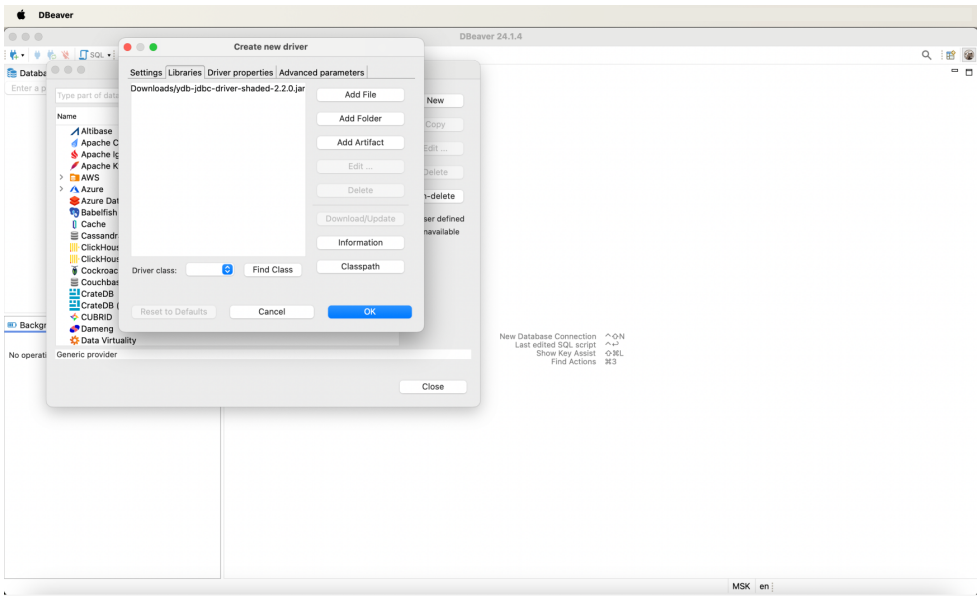


1. Go to the ydb-jdbc-driver repository.
2. Select the latest release (tagged as `Latest`) and save the `ydb-jdbc-driver-shaded-<driver-version>.jar` file.

Follow these steps to connect the downloaded JDBC driver:

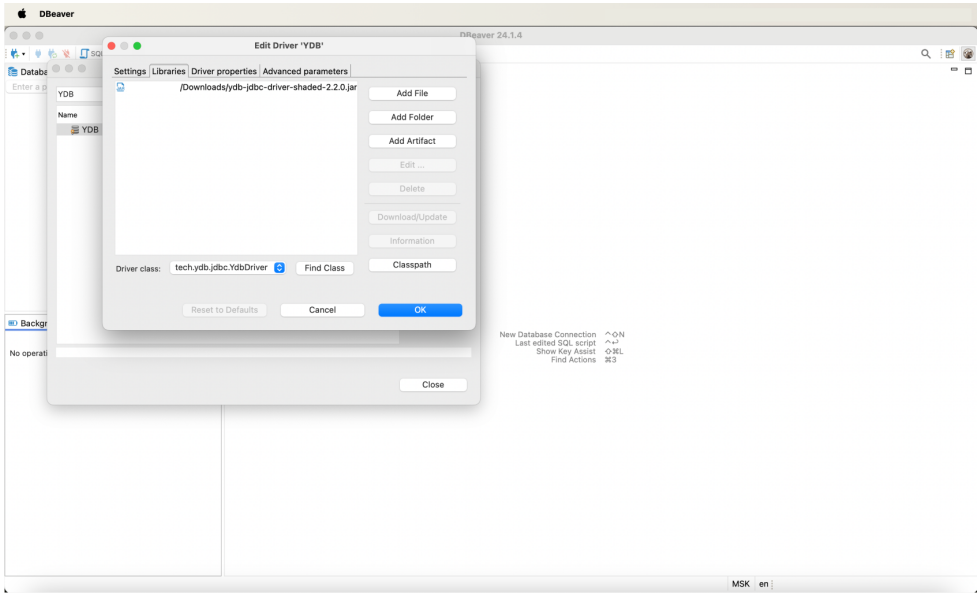


1. In the top menu of DBeaver, select the **Database** option, then select **Driver Manager**:



2. To create a new driver, click the **New** button in the **Driver Manager** window that opens

3. In the **Create Driver** window that opens, specify `YDB` in the **Driver Name** field:

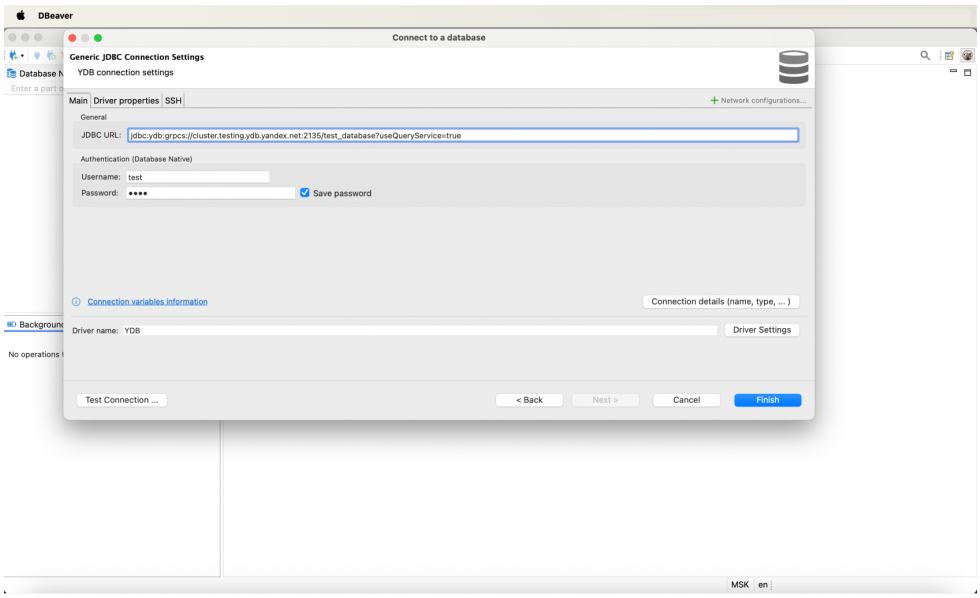


4. Go to the **Libraries** section, click **Add File**, specify the path to the previously downloaded YDB JDBC driver (the `ydb-jdbc-driver-shaded-<driver-version>.jar` file), and click **OK**:

5. The **YDB** item will appear in the list of drivers. Double-click the new driver and go to the **Libraries** tab, click **Find Class**, and select `tech.ydb.jdbc.YdbDriver` from the dropdown list.

> **Warning**
>
> Be sure to explicitly select the `tech.ydb.jdbc.YdbDriver` item from the dropdown list by clicking on it. Otherwise, DBeaver will consider that the driver has not been selected.

Creating a Connection to YDB



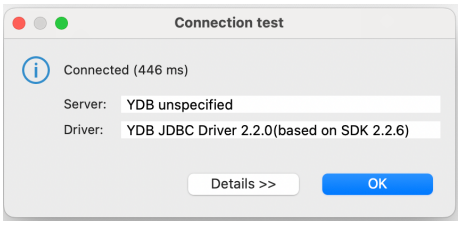
Perform the following steps to establish a connection:

1. In DBeaver, create a new connection, specifying the `YDB` connection type.
2. In the window that opens, go to the **Main** section.
3. In the **General** subsection, in the **JDBC URL** input field, specify the following connection string:

   ```
   jdbc:ydb:<ydb_endpoint>/<ydb_database>?useQueryService=true
   ```

   Where:

   - `ydb_endpoint` — the endpoint of the YDB cluster to which the connection will be made.
   - `ydb_database` — the path to the database in the YDB cluster to which queries will be made.

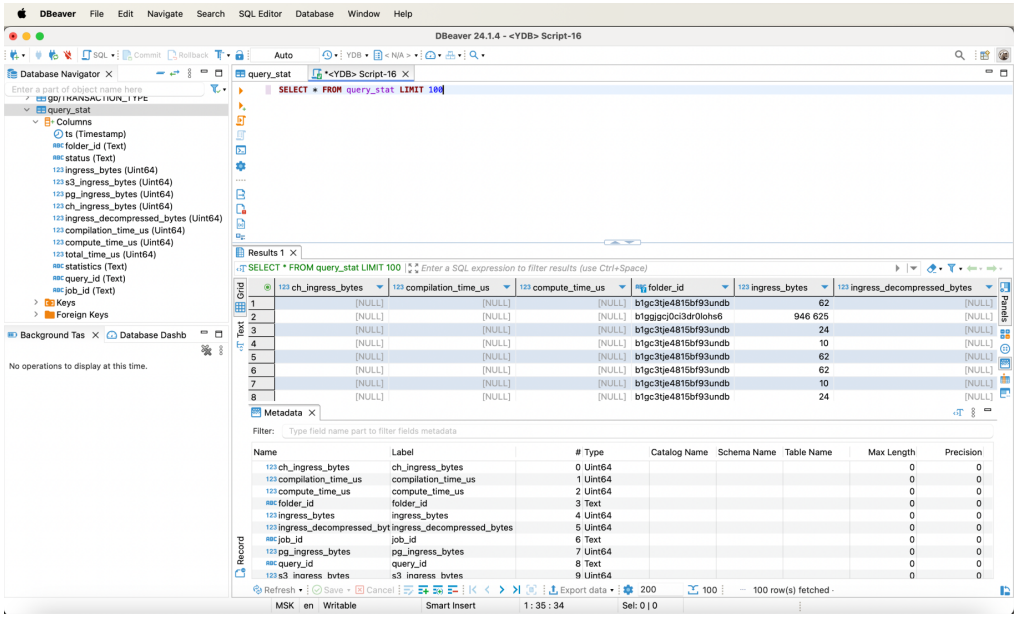


4. In the **User** and **Password** fields, enter the login and password for connecting to the database. A complete list of authentication methods and connection strings for YDB is provided in the JDBC driver description.

> **Note**
>
> In Managed installations of YDB login and password authentication is not available.

1. Click **Test Connection...** to verify the settings.

   If all settings are correct, a message indicating successful connection testing will appear:



2. Click **Finish** to save the connection.

Working with YDB

With DBeaver, you can view the list and structure of tables:

As well as execute queries on the data:

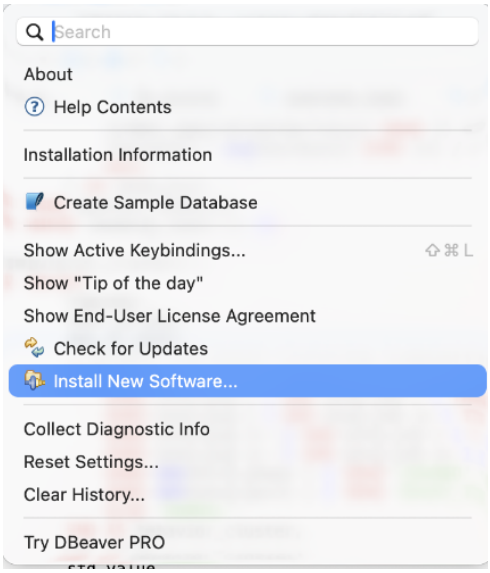
Connecting to YDB Using the DBeaver Plugin

DBeaver is a free cross-platform open-source database management tool that provides a visual interface for connecting to various databases and executing SQL queries.

YDB DBeaver Plugin is a DBeaver extension with native support for YDB. Unlike connecting via a JDBC driver, the plugin provides a specialized interface for working with YDB objects: a hierarchical navigator for tables, topics, views, external data sources, support for all authentication methods, a YQL editor, query execution plan visualization, session and cluster monitoring, access control (ACL) management, and other features.

Key Features of the Plugin

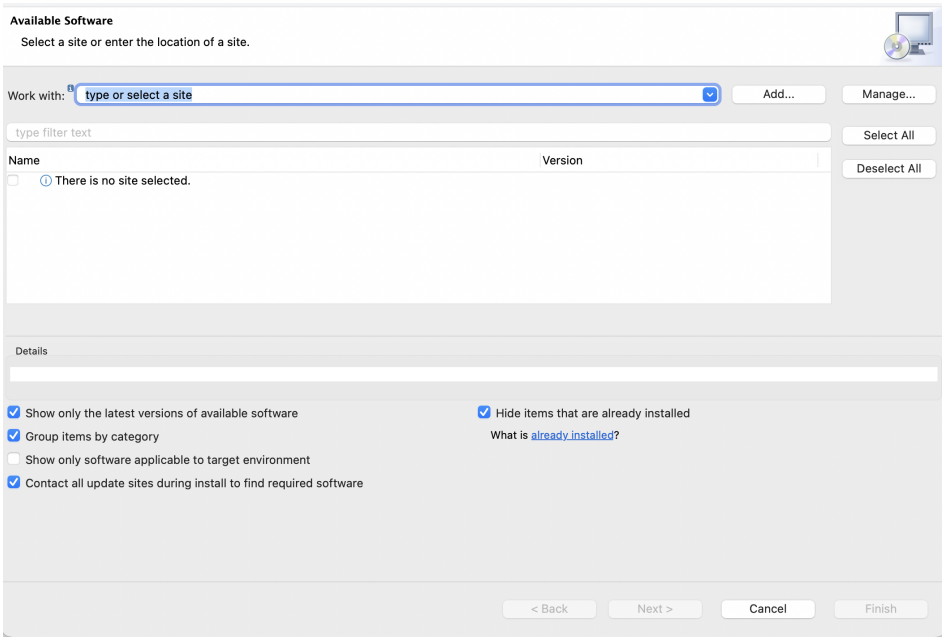
- Connecting to YDB with all authentication methods: anonymous, static, token-based, service account, metadata-based.
- Hierarchical object navigator: tables, topics, external data sources, external tables, views.
- System objects: system views (`.sys`), resource pools, and resource pool classifiers.
- YQL editor with syntax highlighting for over 150 keywords and built-in functions.
- Visualization of the query execution plan (`EXPLAIN` / `EXPLAIN ANALYZE`).
- Monitoring of active sessions via `.sys/query_sessions`.
- Cluster dashboard: CPU load, disk usage, memory usage, network traffic, node status (updated every 5 seconds).
- Access control (ACL) management: granting, revoking, and viewing permissions.
- Management of streaming queries: viewing, modifying, starting, stopping.
- Federated queries via external data sources (S3, databases).
- SQL Dialect Converter from other dialects (PostgreSQL, MySQL, ClickHouse, etc.) to YQL.
- Specialized editors for `JSON`, `JSONDOCUMENT`, `YSON` data types.



Requirements

The plugin requires DBeaver Community Edition version 24.x or later.

Installing the Plugin

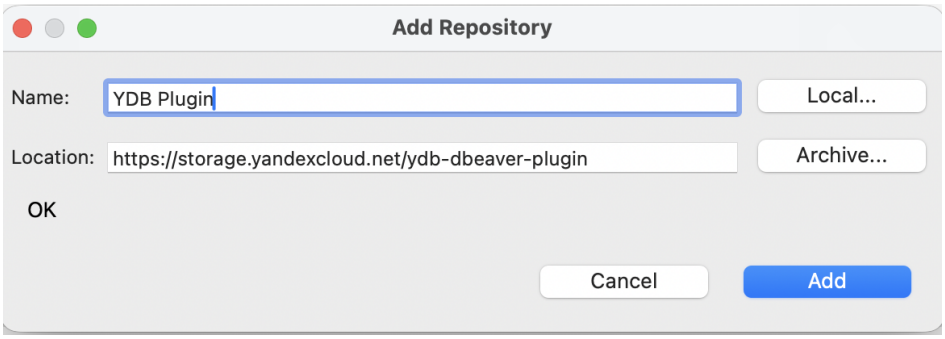


The plugin is installed via DBeaver's extension installation mechanism from a URL repository, which ensures automatic updates.

1. Open DBeaver. In the top menu, select **Help** → **Install New Software...**.
   Screenshot

2. Click the **Add...** button to the right of the **Work with:** field.

Screenshot

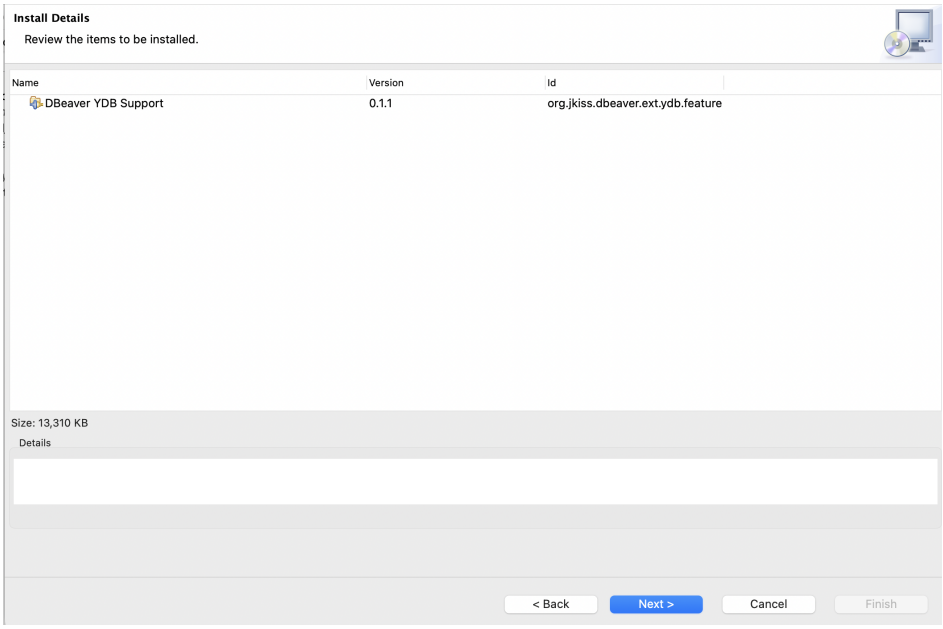


3. In the **Add Repository** window that opens, specify a repository name (for example, `YDB Plugin`) and paste the following URL into the **Location** field:

   ```
   https://storage.yandexcloud.net/ydb-dbeaver-plugin
   ```

   Click **Add**. DBeaver will load the repository metadata.

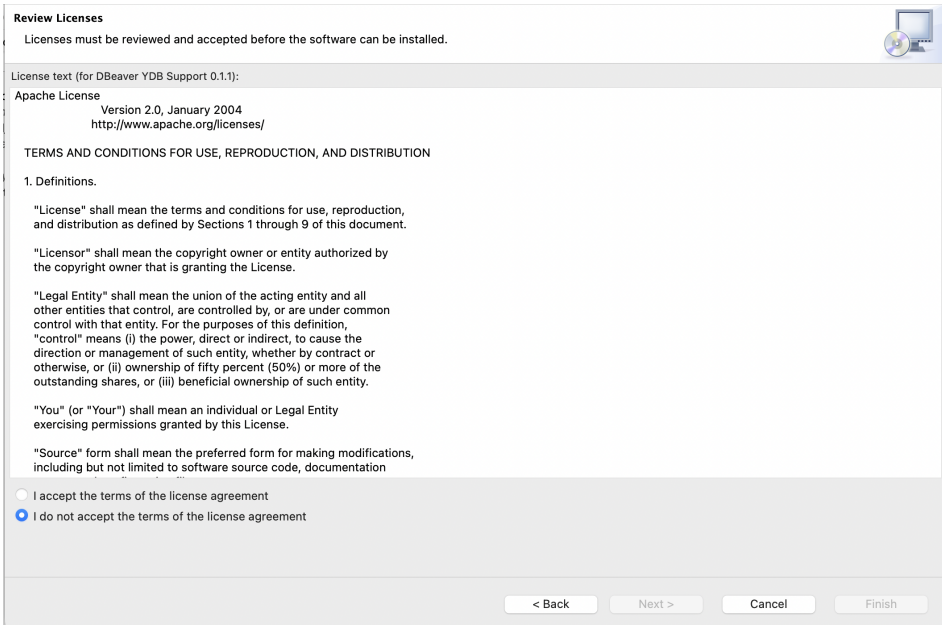
   Screenshot



4. The **DBeaver YDB Support** category will appear in the component list. Select it and click **Next >**.
   Screenshot

5. On the **Install Details** screen, make sure both components (`org.jkiss.dbeaver.ext.ydb` and `org.jkiss.dbeaver.ext.ydb.ui`) are listed, then click **Next >**.

   Screenshot



6. DBeaver may display a warning about unsigned content. This is expected behavior — the plugin's JAR files are not signed with a commercial certificate. Click **Install Anyway**.

> **Note**
>
> Eclipse, on which DBeaver is based, checks JAR file signatures to verify authenticity. This open-source plugin is distributed without a signature; the source code is available in the repository.

7. Review the license (Apache License 2.0), select **I accept the terms of the license agreements**, and click **Finish**.

   Screenshot

8. DBeaver will install the plugin and prompt you to restart. Click **Restart Now**. After restarting, the plugin will become active.

Creating a Connection to YDB

To create a connection to YDB, follow these steps:

1. In the top menu, select **Database** → **New Database Connection** (or press `Ctrl+Shift+N`).
2. In the search field, type `YDB`. Select **YDB** from the list and click **Next**.
3. The YDB connection setup page will open. Fill in the fields:

Field	Description	Example
Host	Host of the endpoint for the YDB cluster	`ydb.example.com`
Port	Port (default is `2135`)	`2135`

Database	Path to the database	`/Root/database`
Monitoring URL	URL of the YDB UI with the database path, used for the dashboard (optional)	`http://ydb.example.com:8765/monitoring/tenant?name=%2FRoot%2Fdatabase`
Use secure connection	Use a secure connection (`grpcs://`)	☑
Enable autocomplete API	Autocomplete via YDB API	☑

4. Select an authentication method from the **Auth type** dropdown list (see Authentication Methods).
5. Click the **Test Connection** button to verify the settings. If the connection is successful, a dialog will appear with the connection time in milliseconds.
6. Click the **Finish** button. The connection will appear in the **Database Navigator** panel.

Authentication Methods

The plugin supports all authentication methods available in YDB. The method is selected from the **Auth type** dropdown list on the connection setup page.

Anonymous

Connection without credentials. Used for local or test installations of YDB. No additional fields need to be filled out.

Static (Username and Password)

Authentication using a username and password. Enter the username in the **User** field and the password in the **Password** field. Used if YDB server has username and password authentication enabled.

> **Note**
>
> In managed installations of YDB, username and password authentication is disabled: managed services use the centralized access control system of the cloud platform (IAM).

Token

Authentication using an IAM or OAuth token. Enter the token in the **Token** field. The token is passed in the header of each request.

Service Account

Authentication using the key of a Yandex Cloud service account. Specify the path to the JSON file with the key in the **SA Key File** field (use the **...** button to select the file). For more information on how to create an authorized key, see the Yandex Cloud documentation.

Key file format:

```
{
  "id": "aje...",
  "service_account_id": "aje...",
  "private_key": "-----BEGIN RSA PRIVATE KEY-----\n..."
}
```

Metadata

Authentication via the Yandex Cloud metadata service. The plugin obtains an IAM token from the virtual machine's metadata service. Used only when DBeaver is running on a Yandex Cloud virtual machine.

Object Navigator

After connecting, the YDB object hierarchy is displayed in the **Database Navigator** panel. The root node is the connection, and inside it is the database path, which contains the following folders:

- **Tables** — tables organized by subdirectories according to the path in YDB (for example, a table with the path `folder1/subfolder/mytable` will be nested under `folder1 → subfolder`).
- **Topics** — topics.
- **Views** — views.
- **External Data Sources** — external data sources.
- **External Tables** — external tables.
- **System Views (.sys)** — system views, such as `partition_stats` , `query_sessions` .
- **Resource Pools** — resource pools.

Working with the Plugin

YQL Editor

Open the **SQL Editor** (`F3` or double-click on the connection). The editor supports:

- Syntax highlighting for YQL: keywords (`UPSERT` , `REPLACE` , `EVALUATE` , `PRAGMA` , `WINDOW` , and 145+ others), data types, built-in functions.
- Autocompletion of table, column, and function names.
- Query execution: `Ctrl+Enter` for the current query, `Ctrl+Shift+Enter` for the entire script.

Example YQL query:

```
UPSERT INTO `users` (id, name, created_at)
VALUES (1, "Alice", CurrentUtcDatetime());
```

EXPLAIN and Execution Plan

Click **Explain** (or `Ctrl+Shift+E`) to get the query execution plan. The plugin displays:

- **Text plan** — a tree of operations in text form.
- **Diagram** — a graphical representation as a DAG.
- **SVG plan** — an interactive visualization.

`EXPLAIN ANALYZE` additionally shows execution statistics (number of rows, execution time).

Session Manager

Right-click on the connection and select **Manage Sessions**, or use the **Database** → **Manage Sessions** menu item. The opened view displays all active sessions with the current query, state, and duration (data from the system view `.sys/query_sessions`). The **Hide Idle** checkbox hides sessions without an active query.

Cluster Dashboard

Open the **Dashboard** tab in the connection editor (requires the **Monitoring URL** field to be filled in during connection setup).

> **Warning**
>
> The dashboard is only available when working with self-hosted installations of YDB where access to the YDB UI is available. In Yandex Cloud Managed Service for YDB, the YDB UI is not published, so dashboard data is unavailable — use cloud platform tools for monitoring.

The dashboard displays real-time data (updated every 5 seconds):

- CPU load by nodes.
- Disk space usage.
- Memory usage.
- Network traffic.
- Number of executing queries.
- Status of cluster nodes.

Streaming Queries

In the navigator, expand the **Streaming Queries** folder. For each query, you can:

- View the original YQL.
- View errors (issues).
- View the execution plan.
- Perform actions: **Start**, **Stop**, **Alter**.

SQL Dialect Converter

The plugin allows you to convert an SQL query written in another dialect (PostgreSQL, MySQL, ClickHouse, etc.) to YQL. The converter is available on the **Convert Dialect** tab in the connection editor.

To convert a query:

1. In the **Source Dialect** dropdown list, select the source SQL dialect. The list of dialects is requested from the plugin's external service when the tab is first opened.
2. Paste the source SQL code into the **Input SQL** field.
3. Click **Convert**. The result will appear in the lower field.
4. Click **Copy** to copy the result to the clipboard.

For more information on how the converter works, supported dialects, and limitations, see the SQL Dialect Converter to YQL article.

> **Warning**
>
> The plugin sends the original query to an external HTTPS service for conversion. Do not use the converter for queries containing confidential data.

Creating Objects

Right-click on a folder or object and select **Create New**:

- **Create Table** — create a new table.
- **Create Topic** — create a new topic.
- **Create Resource Pool** — create a resource pool.

Updating the Plugin

DBeaver uses the Eclipse P2 mechanism to detect and install updates. When you install the plugin, DBeaver remembers the source — the repository URL. When a new version is published, DBeaver compares the installed version with the version in the repository and offers an update in one of two ways:

1. Automatically on the next DBeaver startup (if update checks are enabled in **Window** → **Preferences** → **Install/Update** → **Automatic Updates**).
2. Manually via **Help** → **Check for Updates**: select the available update and follow the same steps as during the initial installation (license → warning about unsigned content → restart).

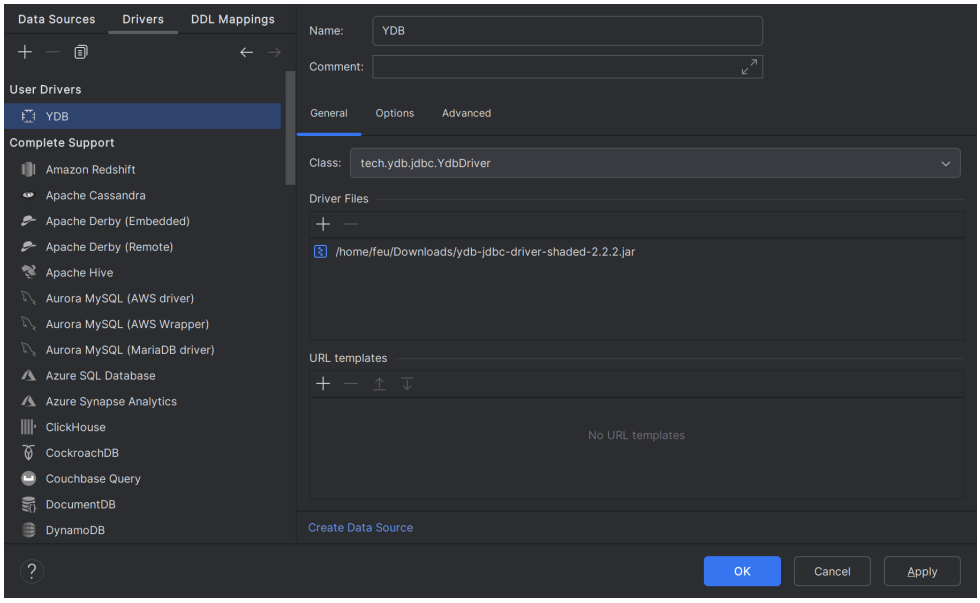
Connecting to YDB with DataGrip

DataGrip is a powerful cross-platform tool for relational and NoSQL databases.

DataGrip allows you to work with YDB using the Java Database Connectivity (JDBC) protocol. This article demonstrates how to set up this integration.

Adding the YDB JDBC Driver to DataGrip

To connect to YDB from DataGrip, you need the YDB JDBC driver.



To download the YDB JDBC driver, follow these steps:

1. Go to the ydb-jdbc-driver repository.
2. Select the latest release (tagged as `Latest`) and save the `ydb-jdbc-driver-shaded-<driver-version>.jar` file.

To add the downloaded JDBC driver to DataGrip, follow these steps:

1. In DataGrip, go to **File | Data Sources...**.

   The **Data Sources and Drivers** dialog box appears.
2. In the **Data Sources and Drivers** dialog box, open the **Drivers** tab and click the **+** button.
3. In the **Name** field, specify `YDB`.
4. In the **Driver Files** section, click the **+** button, choose **Custom JARs...**, specify the path to the previously downloaded YDB JDBC driver (the `ydb-jdbc-driver-shaded-<driver-version>.jar` file), and click **OK**:
5. In the **Class** drop-down list, select `tech.ydb.jdbc.YdbDriver`.

6. Click **OK**.

Creating a Connection to YDB

To establish a connection, perform the following steps:

1. In DataGrip, go to **File | Data Sources...**.

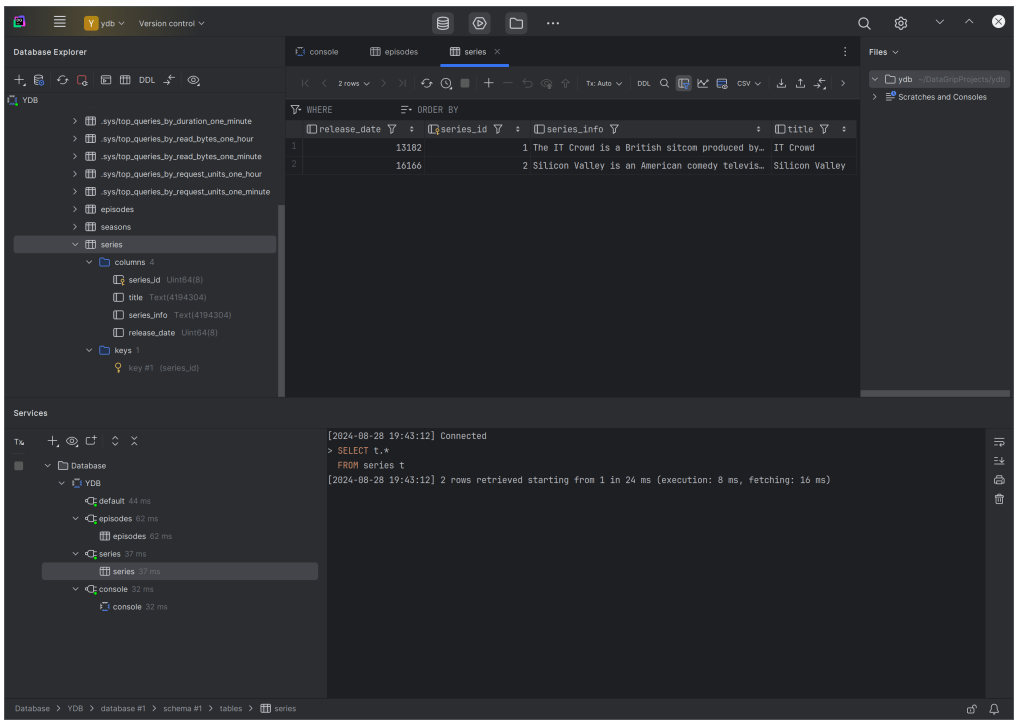
   The **Data Sources and Drivers** dialog box appears.
2. In the **Data Sources and Drivers** dialog box, on the **Data Sources** tab, click the **+** button and select `YDB`.
3. In the **Authentication** drop-down list, select an authentication method.
4. If you selected the `User & Password` authentication method, in the **User** and **Password** fields, enter your YDB login and password.
5. On the **General** tab, in the **URL** field, specify the following connection string:

   ```
   jdbc:ydb:<ydb_endpoint>/<ydb_database>?useQueryService=true
   ```

   Where:

   - `ydb_endpoint` — the endpoint of the YDB cluster.
   - `ydb_database` — the path to the database in the YDB cluster.

   A complete list of authentication methods and connection strings for YDB is provided in the JDBC driver description.



6. Click **Test Connection** to verify the settings.

   If all the settings are correct, a message appears indicating a successful connection test.
7. Click **OK** to save the connection.

Working with YDB

With DataGrip you can view the list and structure of tables.

You can also execute queries on the data.

Work with YDB from Jupyter Notebook

Jupyter Notebook is an open-source tool for creating shareable documents that combine code, plain language descriptions, data, rich visualizations, and interactive controls.

The ydb-sqlalchemy dialect enables working with YDB from tools such as:

- Pandas
- JupySQL

Example

A detailed usage example is available as a notebook.

Prerequisites:

1. Python 3.8+
2. Jupyter Notebook
3. Existing YDB cluster, a single-node one from quickstart will suffice

To run the example, download the notebook file YDB SQLAlchemy - Jupyter Notebook Example.ipynb, open it in Jupyter, and follow each cell sequentially, executing code as necessary.

Data visualization (Business intelligence, BI)

Environment	Compatibility Level	Instruction
Apache Superset	ydb-sqlalchemy	Instruction
DataLens	Full	Instruction
Grafana	Full	Instruction

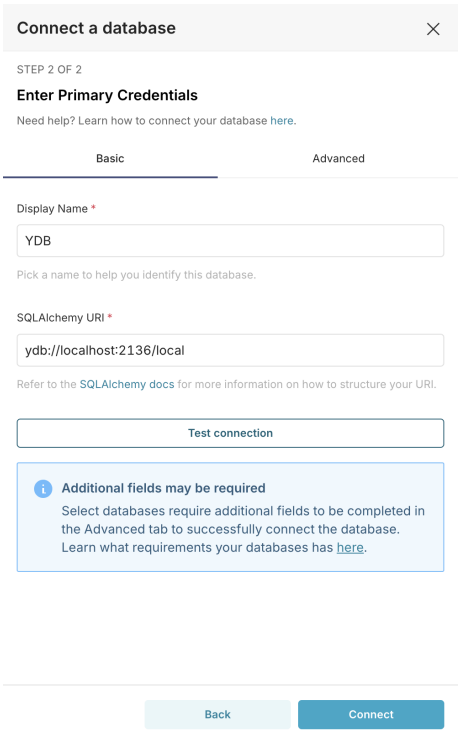
Apache Superset

Apache Superset is a modern data exploration and visualization platform. This article explains how to create visualizations using data stored in YDB.

Installation of dependencies

To connect to YDB from Superset, install the ydb-sqlalchemy driver.

The installation method depends on your Superset setup. For detailed instructions, see the official documentation.



Adding a database connection to YDB

Native connection using SQLAlchemy driver

To connect to YDB from Apache Superset **version 5.0.0 and higher**, follow these steps:

1. In the Apache Superset toolbar, hover over **Settings** and select **Database Connections**.
2. Click the **+ DATABASE** button.

   The **Connect a database** wizard will appear.
3. In **Step 1** of the wizard, choose **YDB** from the **Supported databases** list. If the **YDB** option is not available, make sure that all the steps from prerequisites are completed.
4. In **Step 2** of the wizard, enter the YDB credentials in the corresponding fields:
   - **Display Name**. The YDB connection name in Apache Superset.
   - **SQLAlchemy URI**. A string in the format `ydb://{host}:{port}/{database_name}`, where **host** and **port** are parts of the endpoint of the YDB cluster to which the connection will be made, and **database_name** is the path to the database.

5. To enhance security, you can specify credentials parameters in the **Secure Extra** field under the **Advanced / Security** tab.

   Define the parameters as follows:

   Password

   ```
   {
       "credentials": {
           "username": "...",
           "password": "..."
       }
   }
   ```

   Access Token

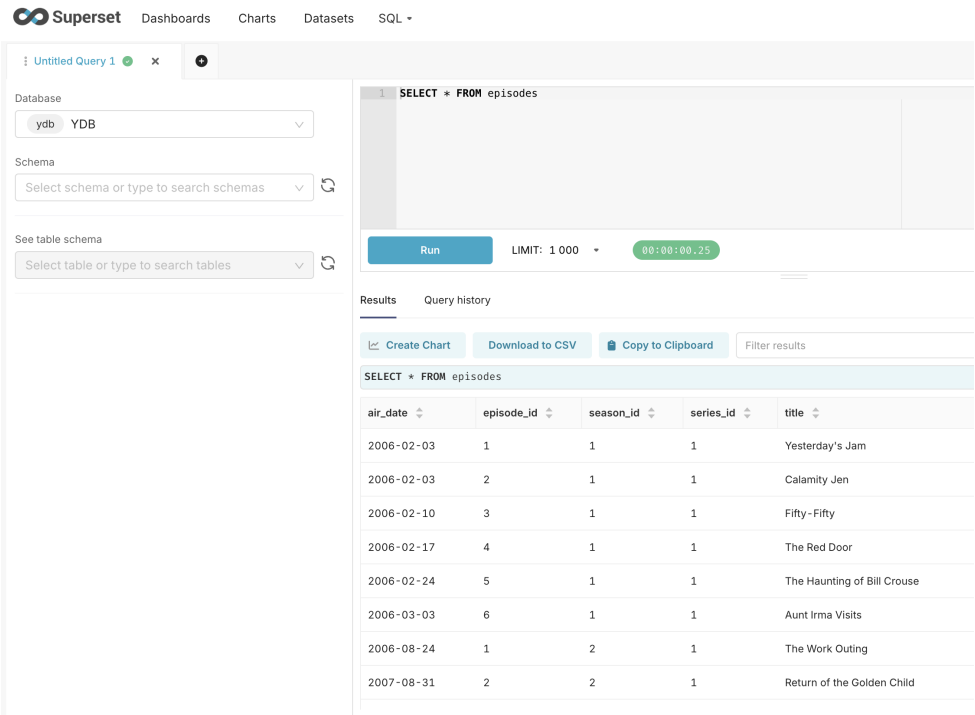
   ```
   {
       "credentials": {
           "token": "...",
       }
   }
   ```

Service Account

```
{
    "credentials": {
        "service_account_json": {
            "id": "...",
            "service_account_id": "...",
            "created_at": "...",
            "key_algorithm": "...",
            "public_key": "...",
            "private_key": "..."
        }
    }
}
```

6. Click **CONNECT**.
7. To save the database connection, click **FINISH**.

For more information about configuring a YDB connection, refer to the YDB section in the official documentation.



Creating a dataset

To create a dataset for a YDB table, follow these steps:

1. In the Apache Superset toolbar, hover over the **+** button and select **SQL query**.
2. In the **DATABASE** drop-down list, select the YDB database connection.
3. Enter the SQL query in the right section of the page. For example, `SELECT * FROM <ydb_table_name>`.

> **Tip**
>
> To create a dataset for a table located in a subdirectory of a YDB database, specify the table path in the table name. For example:
>
> ```
> SELECT * FROM "<path/to/subdirectory/table_name>";
> ```

1. Click **RUN** to test the SQL query.

2. Click the down arrow next to the **SAVE** button, then click **Save dataset**.

   The **Save or Overwrite Dataset** dialog box appears.
3. In the **Save or Overwrite Dataset** dialog box, select **Save as new**, enter the dataset name, and click **SAVE & EXPLORE**.

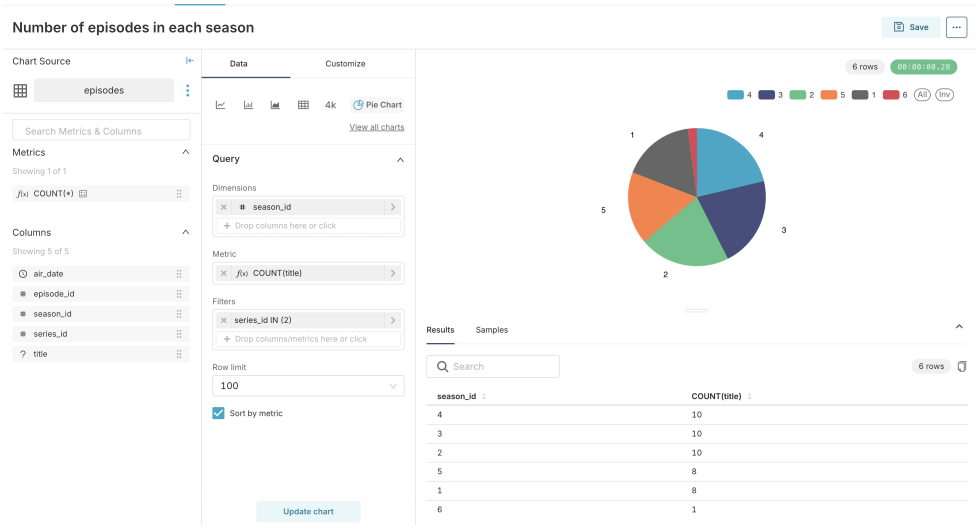
After creating datasets, you can use data from YDB to create charts in Apache Superset. For more information, refer to the Apache Superset documentation.

Creating a chart

Let's create a sample chart with the dataset from the `episodes` table that is described in the YQL tutorial.

The table contains the following columns:

- series_id
- season_id
- episode_id



- title
- air_date

Let's say that we want to make a pie chart to show how many episodes each season contains.

To create a chart, follow these steps:

1. In the Apache Superset toolbar, hover over the **+** button and select **Chart**.
2. In the **Choose a dataset** drop-down list, select a dataset for the `episodes` table.
3. In the **Choose chart type** pane, select `Pie chart`.
4. Click **CREATE NEW CHART**.
5. In the **Query** pane, configure the chart:
   - In the **DIMENSIONS** drop-down list, select the `season_id` column.
   - In the **METRIC** field, specify the `COUNT(title)` function.
   - In the **FILTERS** field, specify the `series_id in (2)` filter.
6. Click **CREATE CHART**.

   The pie chart will appear in the preview pane on the right.

7. Click **SAVE**.

   The **Save chart** dialog box will appear.
8. In the **Save chart** dialog box, in the **CHART NAME** field, enter the chart name.
9. Click **SAVE**.

DataLens

DataLens is an open-source business intelligence (BI) and data visualization tool that enables users to analyze and display data from various sources, including YDB. DataLens allows you to describe data models, create charts and other visualizations, build dashboards, and provide collaborative access to analytics.

Prerequisites

DataLens must be deployed and configured.

> **Note**
>
> This article covers the integration of self-managed YDB and DataLens. For documentation on integrating the respective managed services, refer to the Yandex Cloud documentation.

Adding a database connection to YDB

To create a connection to YDB:

1. Go to the workbook page or create a new one.
2. In the top right corner, click **Create** → **Connection**.
3. Select the **YDB** connection.
4. Choose an authentication type:

   Anonymous

   - **Host name**. Specify the hostname for YDB connection.
   - **Port**. Specify the connection port for YDB. The default port is 2135.
   - **Database path**. Specify the name of the database to connect to.

   Password

   - **Host name**. Specify the hostname for YDB connection.
   - **Port**. Specify the connection port for YDB. The default port is 2135.
   - **Database path**. Specify the name of the database to connect to.
   - **Username**. Enter the username to connect to YDB.
   - **Password**. Enter the user password.

   OAuth

   - **OAuth token**. Provide the OAuth token to access YDB.
   - **Host name**. Specify the hostname for YDB connection.
   - **Port**. Specify the connection port for YDB. The default port is 2135.
   - **Database path**. Specify the name of the database to connect to.
   - **Cache lifetime in seconds**. Set the cache lifetime or leave the default value. The recommended value is 300 seconds (5 minutes).
   - **SQL query access level**. Allows the use of custom SQL queries to create a dataset.
5. Click **Create connection**.
6. Specify a connection name and click **Create**.
7. Proceed to creating a dataset.

Example

YDB data source for Grafana

The YDB data source plugin allows you to use Grafana to query and visualize data from YDB.

Installation

Prerequisites: the plugin requires Grafana v9.2 or higher.

Follow the Grafana's plugin installation docs to install a plugin named `ydb-grafana-datasource-plugin`.

Configuration

YDB user for the data source

Set up an YDB user account with **read-only** permissions (more about permissions) and access to databases and tables you want to query.

> **Warning**
>
> Please note that Grafana does not validate that queries are safe. Queries can contain any SQL statements, including data modification instructions.

Data transfer protocol support

The plugin supports gRPC and gRPCS transport protocols.

Configuration via UI

Once the plugin is installed on your Grafana instance, follow these instructions to add a new YDB data source, and enter configuration options.

Configuration with provisioning system

Alternatively, Grafana's provisioning system allows you to configure data sources using configuration files. To read about how it works, including all the settings you can set for this data source, refer to the Provisioning Grafana data sources documentation.

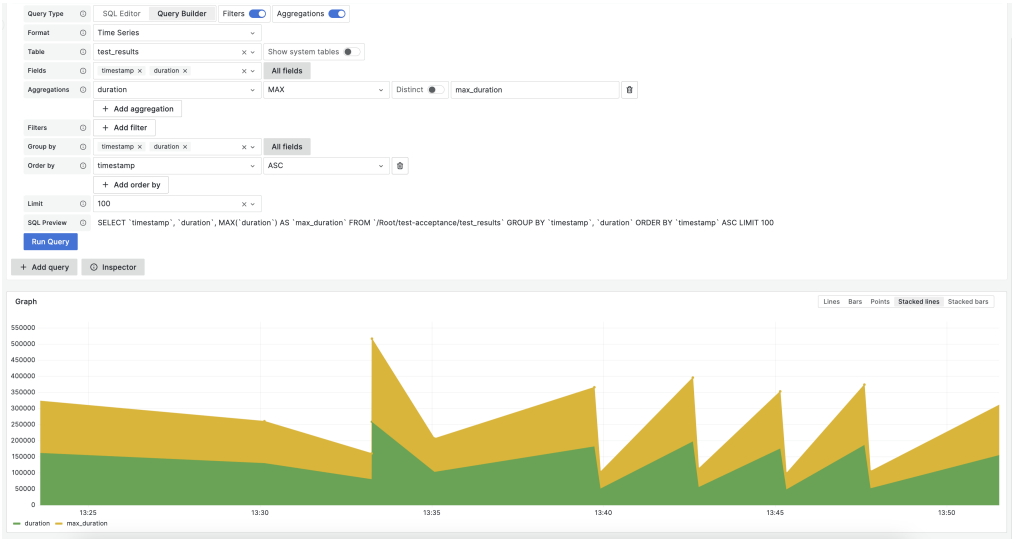
Authentication

The Grafana plugin supports the following authentication methods: Anonymous, Access Token, Metadata, Service Account Key and Static Credentials.

Below is an example config for authenticating a YDB data source using username and password:

```
apiVersion: 1
datasources:
  - name: YDB
    type: ydbtech-ydb-datasource
    jsonData:
      authKind: '<password>'
      endpoint: 'grpcs://<hostname>:2135'
      dbLocation: '<location_to_db>'
      user: '<username>'
    secureJsonData:
      password: '<userpassword>'
      certificate: |
        <full content of *.pem file>
```

Here are fields that are supported in connection configuration:



Name	Description	Type
authKind	Authentication type	`"Anonymous"`, `"ServiceAccountKey"`, `"AccessToken"`, `"UserPassword"`, `"MetaData"`
endpoint	Database endpoint	`string`
dbLocation	Database location	`string`
user	User name	`string`
serviceAccAuthAccessKey	Service account access key	`string` (secured)
accessToken	Access token	`string` (secured)
password	User password	`string` (secured)
certificate	If self-signed certificates are used on your YDB cluster nodes, specify the Certificate Authority certificate used to issue them	`string` (secured)

Building queries

YDB is queried with a SQL dialect named YQL.
The query editor allows to get data in different representations: time series, table, or logs.

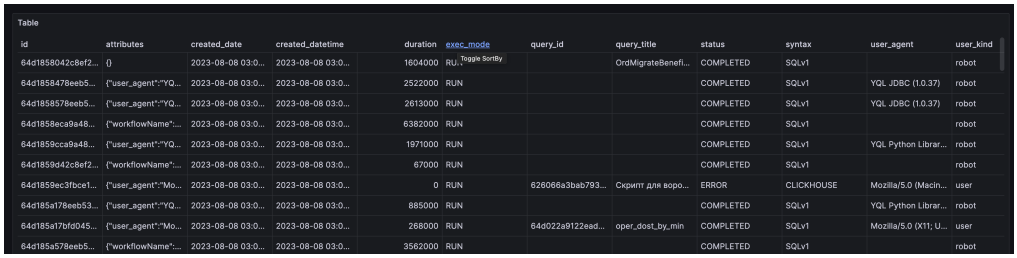
Time series

Time series visualization options are selectable if the query returns at least one field with `Date`, `Datetime`, or `Timestamp` type (for now, working with time is supported only in UTC timezone) and at least one field with `Int64`, `Int32`, `Int16`, `Int8`, `Uint64`, `Uint32`, `Uint16`, `Uint8`, `Double` or `Float` type. Then, you can select time series visualization options. Any other column is treated as a value column.

Multi-line time series

To create a multi-line time series, the query must return at least 3 fields:

- field with `Date`, `Datetime` or `Timestamp` type (for now, working with time is supported only in UTC timezone)
- metric - field with `Int64`, `Int32`, `Int16`, `Int8`, `Uint64`, `Uint32`, `Uint16`, `Uint8`, `Double` or `Float` type
- either metric or field with `String` or `Utf8` type - the value for splitting metrics into separate series.



For example:

```
SELECT
    `timestamp`,
    `responseStatus`
    AVG(`requestTime`) AS `avgReqTime`
FROM `/database/endpoint/my-logs`
GROUP BY `responseStatus`, `timestamp`
ORDER BY `timestamp`
```

> **Tip**
>
> For this kind of queries, using column-oriented tables will likely be beneficial in terms of performance.

Tables

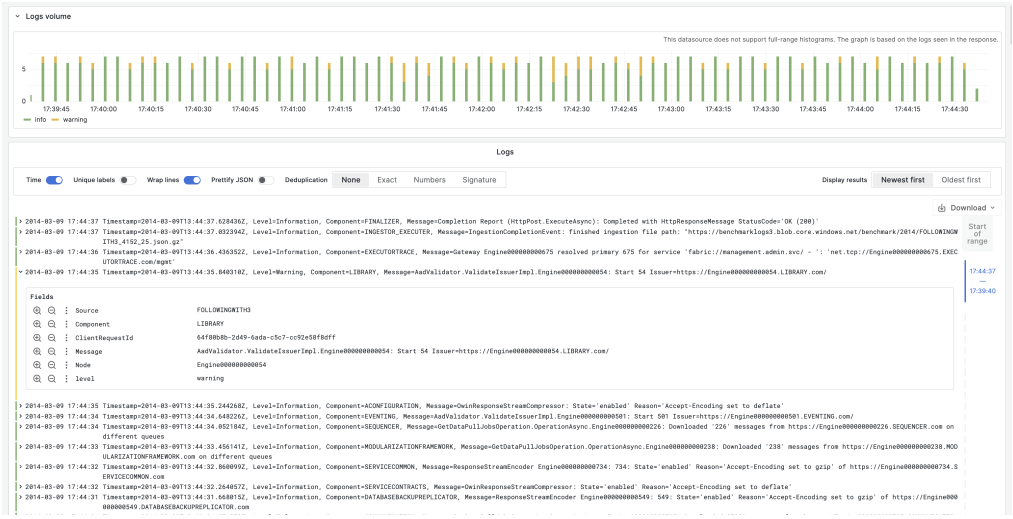


Table visualizations will always be available for any valid YDB query that returns exactly one result set.

Visualizing logs with the Logs Panel

To use the Logs panel, your query must return a `Date`, `Datetime`, or `Timestamp` value and a `String` value. You can select logs visualizations using the visualization options.

Only the first text field will be represented as a log line by default. This behavior can be customized using the query builder.

Macros

The query can contain macros, which simplify syntax and allow for dynamic parts, like date range filters.
There are two kinds of macros - Grafana-level and YDB-level. The plugin will parse query text and, before sending it to YDB, substitute variables and Grafana-level macros with particular values. After that YDB-level macroses will be treated by YDB server-side.

Here is an example of a query with a macro that will use Grafana's time filter:

```
SELECT `timeCol`
FROM `/database/endpoint/my-logs`
WHERE $__timeFilter(`timeCol`)
```

```
SELECT `timeCol`
FROM `/database/endpoint/my-logs`
WHERE $__timeFilter(`timeCol` + Interval("PT24H"))
```

Macro	Description	Output example
`$__timeFilter(expr)`	Replaced by a conditional that filters the data (using the provided column or expression) based on the time range of the panel in microseconds	`foo >= CAST(1636717526371000 AS Timestamp) AND foo <= CAST(1668253526371000 AS Timestamp)' )`
`$__fromTimestamp`	Replaced by the starting time of the range of the panel cast to Timestamp	`CAST(1636717526371000 AS Timestamp)`
`$__toTimestamp`	Replaced by the ending time of the range of the panel cast to Timestamp	`CAST(1636717526371000 AS Timestamp)`
`$__varFallback(condition, $templateVar)`	Replaced by the first parameter when the template variable in the second parameter is not provided.	

Templates and variables

To add a new YDB query variable, refer to Add a query variable.
After creating a variable, you can use it in your YDB queries by using Variable syntax.
For more information about variables, refer to Templates and variables.

Learn more

- Add Annotations.
- Configure and use Templates and variables.

- Add Transformations.
- Set up alerting; refer to Alerts overview.

Orchestration

System	Instruction
Apache Airflow™	Instruction

Apache Airflow™

Integration of YDB with Apache Airflow™ allows you to automate and manage complex workflows. Apache Airflow™ provides features for scheduling tasks, monitoring their execution, and managing dependencies between them, such as orchestration. Using Airflow to orchestrate tasks such as uploading data to YDB, executing queries, and managing transactions allows you to automate and optimize operational processes. This is especially important for ETL tasks, where large amounts of data require regular extraction, transformation, and loading.

YDB provider package apache-airflow-providers-ydb allows to work with YDB from Apache Airflow™. Apache Airflow™ tasks are Python applications consisting of a set of Apache Airflow™ operators and their dependencies, defining the order of execution.

Setup

Execute the following command on all Apache Airflow™ hosts to install the `apache-airflow-providers-ydb` package:

```
pip install ydb apache-airflow-providers-ydb
```

Python version 3.8 or higher is required.

Object model

The `airflow.providers.ydb` package contains a set of components for interacting with YDB:

- Operator `YDBExecuteQueryOperator` for integrating tasks into the Apache Airflow™ scheduler.
- Hook `YDBHook` for direct interaction with YDB.

YDBExecuteQueryOperator

To make requests to YDB, use the Apache Airflow™ operator `YDBExecuteQueryOperator`.

Required arguments

- `task_id` — the name of the Apache Airflow™ task.
- `sql` — the text of the SQL query to be executed in YDB.

Optional arguments

- `ydb_conn_id` — the connection identifier with the `YDB` type, containing the connection parameters for YDB. If omitted, a connection named `ydb_default` is used. The `ydb_default` connection is preinstalled as part of Apache Airflow™ and does not need to be configured separately.
- `is_ddl` — indicates that SQL DDL is running. If omitted or set to `False`, then SQL DML is running.
- `params` — a dictionary of query parameters.

Example:

```
ydb_operator = YDBExecuteQueryOperator(task_id="ydb_operator", sql="SELECT 'Hello, world!'")
```

In this example, a Apache Airflow™ task is created with the ID `ydb_operator`, which executes the query `SELECT 'Hello, world!'`.

YDBHook

The Apache Airflow™ class `YDBHook` is used to execute low-level commands in YDB.

Optional arguments

- `ydb_conn_id` — the connection identifier with the `YDB` type, containing the connection parameters for YDB. If omitted, a connection named `ydb_default` is used. The `ydb_default` connection is preinstalled as part of Apache Airflow™ and does not need to be configured separately.
- `is_ddl` — indicates that SQL DDL is running. If omitted or set to `False`, then SQL DML is running.

`YDBHook` supports the following methods:

- `bulk_upsert`
- `get_conn`

bulk_upsert

Performs batch data insertion into YDB tables.

Required arguments

- `table_name` — the name of the YDB table where the data will be inserted.
- `rows` — an array of rows to insert.
- `column_types` — a description of column types.

Example:

```
hook = YDBHook(ydb_conn_id=...)
column_types = (
        ydb.BulkUpsertColumns()
        .add_column("pet_id", ydb.OptionalType(ydb.PrimitiveType.Int32))
        .add_column("name", ydb.PrimitiveType.Utf8)
        .add_column("pet_type", ydb.PrimitiveType.Utf8)
        .add_column("birth_date", ydb.PrimitiveType.Utf8)
        .add_column("owner", ydb.PrimitiveType.Utf8)
    )

rows = [
    {"pet_id": 3, "name": "Lester", "pet_type": "Hamster", "birth_date": "2020-06-23", "owner": "Lily"},
    {"pet_id": 4, "name": "Quincy", "pet_type": "Parrot", "birth_date": "2013-08-11", "owner": "Anne"},
]
hook.bulk_upsert("pet", rows=rows, column_types=column_types)
```

In this example, a `YDBHook` object is created, through which the `bulk_upsert` batch data insertion operation is performed.

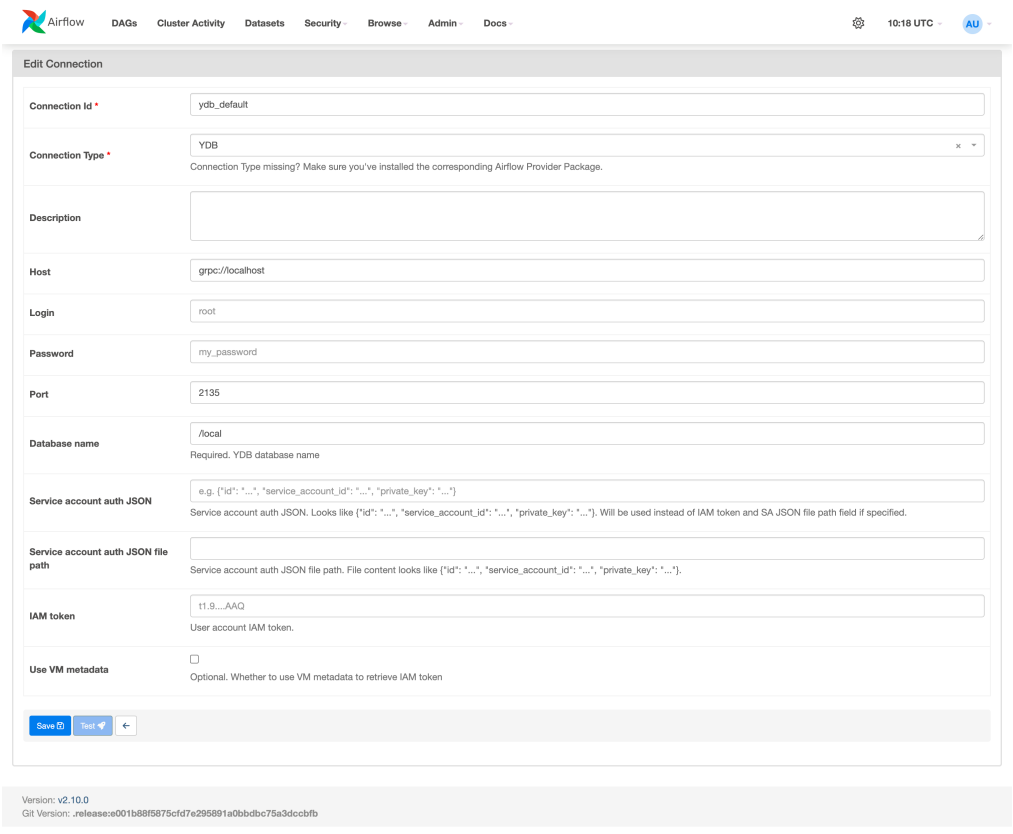
get_conn

Returns the `YDBConnection` object, which implements the `DbApiConnection` interface for working with data. The `DbApiConnection` class provides a standardized interface for interacting with the database, allowing operations such as establishing connections, executing SQL queries, and managing transactions, regardless of the specific database management system.

Example:

```
hook = YDBHook(ydb_conn_id=...)

# Execute the SQL query and get the cursor
connection = hook.get_conn()
cursor = connection.cursor()
cursor.execute("SELECT * from pet;")



# Extract the result and column names
result = cursor.fetchall()
columns = [desc[0] for desc in cursor.description]

# Close cursor and connection
cursor.close()
connection.close()
```

In this example, a `YDBHook` object is created, and a `YDBConnection` object is requested from the created object. This connection is then used to read data and retrieve a list of columns.

Connection to YDB

To connect to YDB, you must create a new or edit an existing Apache Airflow™ connection with the `YDB` type.

Where:

- `Connection Id` — the Apache Airflow™ connection identifier.
- `Host` — the protocol and cluster address of YDB.

- `Port` — the port of YDB.
- `Database name` — the name of the YDB database.

Specify the details for one of the following authentication methods on the YDB cluster:

- `Login` and `Password` — specify user credentials for using static credentials.
- `Service account auth JSON` — specify the value of the `Service Account Key`.
- `Service account auth JSON file path` — specify the path to the `Service Account Key` file.
- `IAM token` — specify the IAM token.
- `Use VM metadata` — enable this option to use virtual machine metadata.

Matching between YQL and Python types

Below are the rules for converting YQL types to Python results. Types not listed below are not supported.

Scalar types

YQL type	Python type	Example in Python
`Int8`, `Int16`, `Int32`, `Uint8`, `Uint16`, `Uint32`, `Int64`, `Uint64`	`int`	`647713`
`Bool`	`bool`	`True`
`Float`, `float`	`float` NaN and Inf are represented as `None`	`7.88731023` `None`
`Decimal`	`Decimal`	`45.23410083`
`Utf8`	`str`	`"Text of string"`
`String`	`str`	`"Text of string"`

Complex types

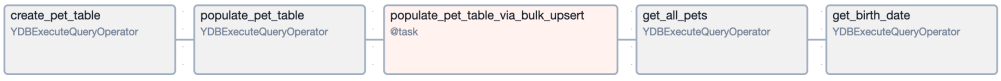
YQL type	Python type	Example in Python
`Json`, `JsonDocument`	`str` (the entire node is inserted as a string)	`{"a":[1,2,3]}`
`Date`	`datetime.date`	`2022-02-09`
`Datetime`, `Timestamp`	`datetime.datetime`	`2022-02-09 10:13:11`

Optional types

YQL type	Python type	Example in Python
`Optional`	Original type or `None`	`1`

Containers

YQL type	Python type	Example in Python
`List<Type>`	`list`	`[1,2,3,4]`
`Dict<KeyType, ValueType>`	`dict`	`{"key1": "value1", "key2": "value2"}`
`Set<KeyType>`	`set`	`{"key_value1", "key_value2"}`
`Tuple<Type1, Type2>`	`tuple`	`(element1, element2)`
`Struct<Name:Utf8, Age:Int32>`	`dict`	`{"Name": "value1", "Age": value2}`



Special types

YQL type	Python type
`Void`, `Null`	`None`
`EmptyList`	`[]`
`EmptyDict`	`{}`

Example

To make requests to YDB, the package provides the Apache Airflow™ operator `YDBExecuteQueryOperator` and hook `YDBHook`.

In the example below, a `create_pet_table` task is launched to create a table in YDB. After the table is successfully created, the `populate_pet_table` task runs to populate the table with data using `UPSERT` commands. Additionally, the `populate_pet_table_via_bulk_upsert` task fills the table using `bulk_upsert`. After data insertion, a read operation is performed using the `get_all_pets` task and the `get_birth_date` task for parameterized data reading.

To execute queries in YDB, a pre-created connection of type YDB Connection named `test_ydb_connection` is used.

```
from __future__ import annotations

import datetime

import ydb
from airflow import DAG
from airflow.decorators import task
from airflow.providers.ydb.hooks.ydb import YDBHook
from airflow.providers.ydb.operators.ydb import YDBExecuteQueryOperator

@task
def populate_pet_table_via_bulk_upsert():
    hook = YDBHook(ydb_conn_id="test_ydb_connection")
    column_types = (
        ydb.BulkUpsertColumns()
        .add_column("pet_id", ydb.OptionalType(ydb.PrimitiveType.Int32))
        .add_column("name", ydb.PrimitiveType.Utf8)
        .add_column("pet_type", ydb.PrimitiveType.Utf8)
        .add_column("birth_date", ydb.PrimitiveType.Utf8)
        .add_column("owner", ydb.PrimitiveType.Utf8)
    )

    rows = [
        {"pet_id": 3, "name": "Lester", "pet_type": "Hamster", "birth_date": "2020-06-23", "owner": "Lily"},
        {"pet_id": 4, "name": "Quincy", "pet_type": "Parrot", "birth_date": "2013-08-11", "owner": "Anne"},
    ]
    hook.bulk_upsert("pet", rows=rows, column_types=column_types)

Log records collection using FluentBit

This section describes the integration between YDB and the log capture tool FluentBit to save and analyze the log records in YDB.

Overview

FluentBit is a tool that can collect text data, manipulate it (modify, transform, combine), and send it to various repositories for further processing. A custom plugin library for FluentBit has been developed to support saving the log records into YDB. The library's source code is available in the fluent-bit-ydb repository.

Deploying a log delivery scheme using FluentBit and YDB as the destination database includes the following steps:

1. Create YDB tables for the log data storage
2. Deploy FluentBit and YDB plugin for FluentBit
3. Configure FluentBit to collect and process the logs
4. Configure FluentBit to send the logs to YDB tables

Creating tables for log data

Tables for log data storage must be created in the chosen YDB database. The structure of the tables is determined by a set of fields of a specific log supplied using FluentBit. Depending on the requirements, different log types may be saved to different tables. Normally, the table for log data contains the following fields:

- timestamp
- log level
- hostname
- service name
- message text or its semi-structural representation as JSON document

YDB tables must have a primary key, uniquely identifying each table's row. A timestamp does not always uniquely identify messages coming from a particular source because messages might be generated simultaneously. To enforce the uniqueness of the primary key, a hash value can be added to the table. The hash value is computed using the CityHash64 algorithm over the log record data.

Row-based and columnar tables can both be used for log data storage. Columnar tables are recommended, as they support more efficient data scans for log data retrieval.

Example of the row-based table for log data storage:

```
CREATE TABLE `fluent-bit/log` (
    `timestamp`         Timestamp NOT NULL,
    `hostname`          Text NOT NULL,
    `input`             Text NOT NULL,
    `datahash`          Uint64 NOT NULL,
    `level`             Text NULL,
    `message`           Text NULL,
    `other`             JsonDocument NULL,
    PRIMARY KEY (
         `datahash`, `timestamp`, `hostname`, `input`
    )
);
```

Example of the columnar table for log data storage:

```
CREATE TABLE `fluent-bit/log` (
    `timestamp`         Timestamp NOT NULL,
    `hostname`          Text NOT NULL,
    `input`             Text NOT NULL,
    `datahash`          Uint64 NOT NULL,
    `level`             Text NULL,
    `message`           Text NULL,
    `other`             JsonDocument NULL,
    PRIMARY KEY (
         `timestamp`, `hostname`, `input`, `datahash`
    )
) PARTITION BY HASH(`timestamp`, `hostname`, `input`)
  WITH (STORE = COLUMN);
```

The command that creates the columnar table differs in the following details:

- it specifies the columnar storage type and the table's partitioning key in the last two lines;
- the `timestamp` column is the first column of the primary key, which is optimal and recommended for columnar, but not for row-based tables. See the specific guidelines for choosing the primary key for columnar tables and for row-based tables.

TTL configuration can be optionally applied to the table, limiting the data storage period and enabling the automatic removal of obsolete data. Enabling TTL requires an extra setting in the `WITH` section of the table creation command. For example, `TTL = Interval("P14D") ON timestamp` sets the storage period to 14 days, based on the `timestamp` field's value.

FluentBit deployment and configuration

FluentBit deployment should be performed according to its documentation.

YDB plugin for FluentBit is available in the source code form in the repository, along with the build instructions. A docker image is provided for container-based deployments: `ghcr.io/ydb-platform/fluent-bit-ydb`.

General logic, configuration syntax and procedures to set up the receiving, processing, and delivering logs in the FluentBit environment are defined in the corresponding FluentBit documentation.

Writing logs to YDB tables

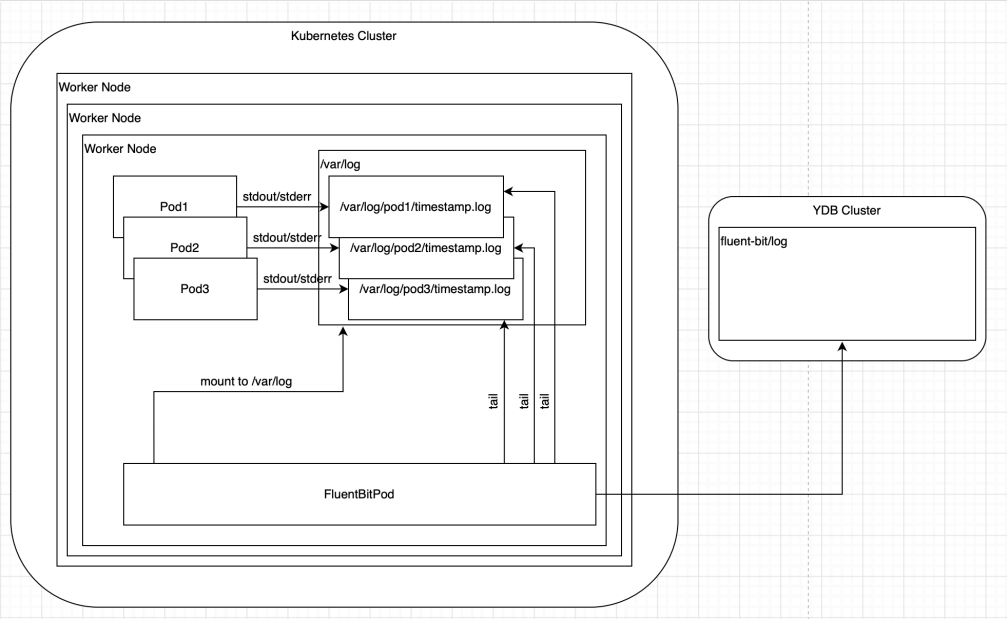
Before using the YDB output plugin, it needs to be enabled in the FluentBit settings. The list of the enabled FluentBit plugins is configured in a file (for example, `plugins.conf`), which is referenced through the `plugins_file` parameter in the `SERVICE` section of the main FluentBit configuration file. Below is the example of such a file with YDB plugin enabled (plugin library path may be different depending on your setup):

```
# plugins.conf
[PLUGINS]
    Path /usr/lib/fluent-bit/out_ydb.so
```

The table below lists the configuration parameters supported by the YDB output plugin for FluentBit.

Parameter	Description
`Name`	Plugin type, should be value `ydb`
`Match`	(optional) Tag matching expression to select log records which should be routed to YDB
`ConnectionURL`	YDB connection URL, including the protocol, endpoint, and database path (see the documentation)
`TablePath`	Table path starting from database root (example: `fluent-bit/log`)
`Columns`	JSON structure mapping the fields of FluentBit record to the columns of the target YDB table. May include the pseudo-columns listed below
`CredentialsAnonymous`	Configured as `1` for anonymous YDB authentication
`CredentialsToken`	Token value, to use the token authentication YDB mode
`CredentialsYcMetadata`	Configure as `1` for virtual machine metadata YDB authentication
`CredentialsStatic`	Username and password for YDB authentication, specified in the following format: `username:password@`
`CredentialsYcServiceAccountKey`	Path of a file containing the service account (SA) key, to use the SA key YDB authentication
`CredentialsYcServiceAccountKeyJson`	JSON data of the service account key to be used instead of the filename (useful in K8s environment)
`Certificates`	Path to the certificate authority (CA) trusted certificates file, or the literal trusted CA certificate value
`LogLevel`	Plugin-specific logging level should be one of `disabled` (default), `trace`, `debug`, `info`, `warn`, `error`, `fatal` or `panic`

The following pseudo-columns are available, in addition to the actual FluentBit log record fields, to be used as source values in the column map (`Columns` parameter):



- `.timestamp` - log record timestamp (mandatory)
- `.input` - log input stream name (mandatory)
- `.hash` - uint64 hash code, computed over the log record fields (optional)
- `.other` - JSON document containing all log record fields that were not explicitly mapped to any table column (optional)

Example of `Columns` parameter value:

```
{".timestamp": "timestamp", ".input": "input", ".hash": "datahash", "log": "message", "level": "level", "hos
t": "hostname", ".other": "other"}
```

Collecting logs in a Kubernetes cluster

FluentBit is often used to collect logs in the Kubernetes environment. Below is the schema of the log delivery process, implemented using FluentBit and YDB, for applications running in the Kubernetes cluster:

In this diagram:

- Application pods write logs to stdout/stderr
- Text from stdout/stderr is saved as files on Kubernetes worker nodes
- Pod with FluentBit:
  - Mounts a folder with log files for itself
  - Reads the contents from the log files
  - Enriches log records with additional metadata
  - Saves records to YDB database

Table to store Kubernetes logs

Below is the YDB table structure to store the Kubernetes logs:

```
CREATE TABLE `fluent-bit/log` (
    `timestamp`         Timestamp NOT NULL,
    `file`              Text NOT NULL,
    `pipe`              Text NOT NULL,
    `message`           Text NULL,
    `datahash`          Uint64 NOT NULL,
    `message_parsed`    JSON NULL,
    `kubernetes`        JSON NULL,

    PRIMARY KEY (
         `timestamp`, `file`, `datahash`
    )
) PARTITION BY HASH(`timestamp`, `file`)
  WITH (STORE = COLUMN, TTL = Interval("P14D") ON `timestamp`);
```

Columns purpose:

- `timestamp` – the log record timestamp;
- `file` – the name of the source from which the log was read. In the case of Kubernetes, this will be the name of the file on the worker node in which the logs of a specific pod are written;
- `pipe` – stdout or stderr stream where application-level writing was done;
- `datahash` – hash code computed over the log record;
- `message` – the textual part of the log record;
- `message_parsed` – log record fields in the structured form, if it could be parsed using the configured FluentBit parsers from the textual part;
- `kubernetes` – information about the pod, including name, namespace, and annotations.

Optionally, TTL can be configured for the table, as shown in the example.

FluentBit configuration

In order to deploy FluentBit in the Kubernetes environment, a configuration file with the log collection and processing parameters must be prepared (typical file name: `values.yaml`). This section provides the necessary comments on this file's content with the examples.

It is necessary to replace the repository and image version of the FluentBit container:

```
image:
  repository: ghcr.io/ydb-platform/fluent-bit-ydb
  tag: latest
```

In this image, a plugin library has been added that implements YDB support.

The following lines define the rules for mounting log folders in FluentBit pods:

```
volumeMounts:
  - name: config
    mountPath: /fluent-bit/etc/conf

daemonSetVolumes:
  - name: varlog
    hostPath:
      path: /var/log
  - name: varlibcontainers
    hostPath:
      path: /var/lib/containerd/containers
  - name: etcmachineid
    hostPath:
      path: /etc/machine-id
      type: File

daemonSetVolumeMounts:
  - name: varlog
    mountPath: /var/log
  - name: varlibcontainers
    mountPath: /var/lib/containerd/containers
    readOnly: true
  - name: etcmachineid
    mountPath: /etc/machine-id
    readOnly: true
```

FluentBit startup parameters should be configured as shown below:

```
command:
  - /fluent-bit/bin/fluent-bit

args:
  - --workdir=/fluent-bit/etc
  - --plugin=/fluent-bit/lib/out_ydb.so
  - --config=/fluent-bit/etc/conf/fluent-bit.conf
```

The FluentBit pipeline for collecting, converting, and delivering logs should be defined according to the example:

```
config:
  inputs: |
    [INPUT]
        Name tail
        Path /var/log/containers/*.log
        multiline.parser cri
        Tag kube.*
        Mem_Buf_Limit 5MB
        Skip_Long_Lines On

  filters: |
    [FILTER]
        Name kubernetes
        Match kube.*
        Keep_Log On
        Merge_Log On
        Merge_Log_Key log_parsed
        K8S-Logging.Parser On
        K8S-Logging.Exclude On

    [FILTER]
        Name modify
        Match kube.*
        Remove time
        Remove _p

  outputs: |
    [OUTPUT]
        Name ydb
        Match kube.*
        TablePath fluent-bit/log
        Columns {".timestamp":"timestamp",".input":"file",".hash":"datahash","log":"message","log_parsed":"me
ssage_structured","stream":"pipe","kubernetes":"metadata"}
        ConnectionURL ${OUTPUT_YDB_CONNECTION_URL}
        CredentialsToken ${OUTPUT_YDB_CREDENTIALS_TOKEN}
```

Configuration blocks description:

- `inputs` - this block specifies where to read and how to parse logs. In this case, `*.log` files will be read from the `/var/log/containers/` folder, which is mounted from the host
- `filters` - this block specifies how the logs will be processed. In this case, for each log record, the corresponding metadata is added (using the Kubernetes filter), and unused fields (`_p` , `time`) are cut out
- `outputs` - this block specifies where the logs will be sent. In this case, logs are saved into the `fluent-bit/log` table in the YDB database. Database connection parameters (in the shown example, `ConnectionURL` and `CredentialsToken`) are defined using the environment variables – `OUTPUT_YDB_CONNECTION_URL` , `OUTPUT_YDB_CREDENTIALS_TOKEN` . Authentication parameters and the set of corresponding environment variables are updated depending on the configuration of the YDB cluster being used.

Environment variables are defined as shown below:

```
env:
  - name: OUTPUT_YDB_CONNECTION_URL
    value: grpc://ydb-endpoint:2135/path/to/database
  - name: OUTPUT_YDB_CREDENTIALS_TOKEN
    valueFrom:
      secretKeyRef:
        key: token
        name: fluent-bit-ydb-plugin-token
```

Authentication data should be stored as the secret object in the Kubernetes cluster configuration. Example command to create a Kubernetes secret:

```
kubectl create secret -n ydb-fluent-bit-integration generic fluent-bit-ydb-plugin-token --from-literal=token=
<YDB TOKEN>
```

Deploying FluentBit in a Kubernetes cluster

HELM is a tool to package and install applications in a Kubernetes cluster. To deploy FluentBit, the corresponding chart repository (containing the installation scenario) should be added using the following command:

```
helm repo add fluent https://fluent.github.io/helm-charts
```

After that, FluentBit can be deployed to a Kubernetes cluster with the following command:

```
helm upgrade --install fluent-bit fluent/fluent-bit \
  --version 0.37.1 \
  --namespace ydb-fluent-bit-integration \
  --create-namespace \
  --values values.yaml
```

The argument `--values` in the example command shown above references the file containing the FluentBit settings.

Installation verification

Check that FluentBit has started by reading its logs (there should be no `[error]` level entries):

```
kubectl logs -n ydb-fluent-bit-integration -l app.kubernetes.io/instance=fluent-bit
```

Check that there are records in the YDB table (they will appear approximately a few minutes after launching FluentBit):

```
SELECT * FROM `fluent-bit/log` LIMIT 10 ORDER BY `timestamp` DESC;
```

Resources cleanup

To remove FluentBit, it is sufficient to delete the Kubernetes namespace which was used for the installation:

```
kubectl delete namespace ydb-fluent-bit-integration
```

After uninstalling FluentBit, the log storage table can be dropped from the YDB database:

```
DROP TABLE `fluent-bit/log`;
```

Integrating Logstash and YDB

This section describes the integration options between YDB and Logstash, a server-side data collection and processing pipeline.

Introduction

Logstash dynamically ingests, transforms, and ships data regardless of format or complexity. A Logstash pipeline can contain different types of plugins: input, output, and filter. The YDB Logstash plugins repository is hosted on GitHub and contains the following plugins:

- **Storage Plugin** for persisting Logstash events in row-oriented or column-oriented YDB tables;
- **Input Topic Plugin** for reading Logstash events from YDB topics;
- **Output Topic Plugin** for sending Logstash events to YDB topics.

These plugins can be built from the source code or downloaded as pre-built artifacts for the two latest versions of Logstash.

> **Note**
>
> Further code snippets use the placeholder `<path-to-logstash>`, which must be replaced by a path to a directory with installed Logstash.

Execute the following command to install any Logstash plugin:

```
<path-to-logstash>/bin/logstash-plugin install </path/to/logstash-plugin.gem>
```

Check that the plugin has been installed:

```
<path-to-logstash>/bin/logstash-plugin list
```

The command will return a list of all installed plugins, which contain the plugin's name.

Configure YDB connection

All plugins use the same set of parameters to configure the connection to YDB. This set contains only one required parameter, `connection_string`. Other parameters are optional and allow configuring an authentication mode. An anonymous mode will be used if the configuration doesn't contain any of these parameters.

```
# This example demonstrates configuration for ydb_storage plugin.
# The plugins ydb_topics_output and ydb_topics_input configure the same way.
ydb_storage {
    # Database connection string contains a schema, hostname, port, and database path
    connection_string => "grpc://localhost:2136/local"
    # Authentication token (for using the "Access Token" mode)
    token_auth => "<token_value>"
    # Authentication token file path (for using the "Access Token" mode)
    token_file => "</path/to/token/file>"
    # Service account key file path (for using the "Service Account Key" mode)
    sa_key_file => "</path/to/key.json>"
    # Flag to use metadata authentication service (for using the "Metadata" mode)
    use_metadata => true
}
```

YDB Storage Plugin

This plugin allows storing the Logstash events stream in YDB tables for further analysis. This is especially useful with column-oriented tables optimized for handling Online Analytical Processing (OLAP) requests. Every field of a Logstash event will be stored in a column with a corresponding name. Fields that do not match any column will be ignored.

Configuration

The plugin configuration is done by adding a `ydb_storage` block in the `output` section of the Logstash pipeline config file. The plugin supports the standard set of connection parameters and a few additional options:

- `table_name` — the required name of the destination table.
- `uuid_column` — the optional name of the column that the plugin will use for storing an auto-generated identifier.
- `timestamp_column` — the optional name of the column that the plugin will use for storing the events' timestamp.

> **Warning**
>
> The Storage plugin doesn't check if the Logstash event has correct and unique values for the table's primary key. It uses the bulk upsert method for storing data in YDB, and if multiple events have the same primary keys, they will overwrite each other. The primary key is recommended to contain those event fields that will be present in every event and can uniquely identify each event. If no such set of fields exists, add an extra column to the primary key and fill it with a random value using the `uuid_column` parameter.

Usage example

Creating a table

Create a new column-oriented table with the necessary columns in any existing YDB database. For example, the table below uses a random value generated by the plugin.

```
CREATE TABLE `logstash_demo` (
    `uuid`     Text NOT NULL,      -- identifier
    `ts`       Timestamp NOT NULL, -- timestamp of event creation
    `message`  Text,
    `user`     Text,
    `level`    Int32,

    PRIMARY KEY (
         `uuid`
    )
)
WITH (STORE = COLUMN);
```

Setup plugin in Logstash pipeline config

To activate the plugin, add the `ydb_storage` block in the `output` section of the Logstash pipeline config. Additionally, add the `http` block in the `input` section for creating test messages via HTTP requests:

```
output {
  ydb_storage {
    connection_string => "..."    # YDB connection string
    table_name => "logstash_demo" # the table name
    uuid_column => "uuid"         # the primary key column with a random UUID
    timestamp_column => "ts"      # the column for storing the event timestamp
  }
}

input {
  http {
    port => 9876 # Any free port
  }
}
```

To apply these changes, restart Logstash.

Send test messages

Send a few test messages:

```
curl -H "content-type: application/json" -XPUT 'http://127.0.0.1:9876/http/ping' -d '{ "user" : "demo_user",
"message" : "demo message", "level": 4}'
curl -H "content-type: application/json" -XPUT 'http://127.0.0.1:9876/http/ping' -d '{ "user" : "test1", "lev
el": 1}'
curl -H "content-type: application/json" -XPUT 'http://127.0.0.1:9876/http/ping' -d '{ "message" : "error",
"level": -3}'
```

All commands return `ok` if the messages are sent.

Check that the messages are stored in YDB

To check that all sent messages are written to the table, run the query with ydb sql (the `ydb table query execute -t scan` command is deprecated):

```
ydb sql -s 'SELECT * FROM `logstash_demo`;'
```

The query will return a list of written events:

```
┌───────┬─────────────┬──────────────────────────────┬─────────────┬──────────────────────────────────────
──┐
| level | message     | ts                           |  user       | uuid
|
├───────┼─────────────┼──────────────────────────────┼─────────────┼──────────────────────────────────────
──┤
| -3    | "error"     | "2024-05-22T13:16:06.491000Z" |  null       | "74cd4048-0b61-4fb9-9385-308714e2188
1" |
|  1    | null        | "2024-05-22T13:15:56.591000Z" | "test1"     | "1df27d0a-9aa0-42c7-9ea2-ab69bc1f5d8
7" |
|  4    | "demo message" | "2024-05-22T13:15:38.760000Z" | "demo_user" | "b7468cb1-e1e3-46fa-965d-83e604e80a3
1" |
└───────┴─────────────┴──────────────────────────────┴─────────────┴──────────────────────────────────────
──┘
```

YDB Topic Input Plugin

This plugin allows reading messages from YDB topics and transforming them into `Logstash` events.

Configuration

The plugin configuration is done by adding a `ydb_topic` block to the `input` section of the Logstash pipeline config. The plugin supports the standard set of connection parameters and a few additional options:

- `topic_path` — the required the full path of the topic for reading.
- `consumer_name` — the required the name of the topic consumer.
- `schema` — the optional mode for processing of the YDB events. By default, the plugin reads and sends messages as binary data, but if you specify the `JSON` mode, each message will be parsed as a JSON object.

Usage example

Create a topic

Create a topic and add a consumer to it in any existing YDB database:

```
ydb -e grpc://localhost:2136 -d /local topic create /local/logstash_demo_topic
ydb -e grpc://localhost:2136 -d /local topic consumer add --consumer logstash-consumer /local/logstash_demo_t
opic
```

Setup plugin in Logstash pipeline config

To activate the plugin, add the `ydb_topic` block in the `input` section of the Logstash pipeline config. Additionally, add the `stdout` plugin in the `output` section for logging all `Logstash` events:

```
input {
  ydb_topic {
    connection_string => "grpc://localhost:2136/local" # YDB connection string
    topic_path => "/local/logstash_demo_topic"         # The full path of the topic to read
    consumer_name => "logstash-consumer"               # The consumer name
    schema => "JSON"                                   # Use JSON mode
  }
}

output {
  stdout { }
}
```

To apply these changes, restart Logstash.

Write a test message to the topic

Send a few test messages to the topic:

```
echo '{"message":"test"}' | ydb -e grpc://localhost:2136 -d /local topic write /local/logstash_demo_topic
echo '{"user":123}' | ydb -e grpc://localhost:2136 -d /local topic write /local/logstash_demo_topic
```

Check if Logstash processed the messages

The `stdout` plugin writes the messages to the Logstash logs:

```
{
      "message" => "test",
      "@timestamp" => 2024-05-23T10:31:47.712896899Z,
      "@version" => "1"
}
{
      "user" => 123.0,
      "@timestamp" => 2024-05-23T10:34:08.574599108Z,

}
```

YDB Topic Output Plugin

This plugin allows writing `Logstash` events to a YDB topic.

Configuration

The plugin configuration is done by adding a `ydb_topic` block to the `output` section of the Logstash pipeline config. The plugin supports the standard set of connection parameters and a few additional options:

- `topic_path` — the required the full path of the topic for writing.

Usage example

Create a topic

Create a topic in any existing YDB database:

```
ydb -e grpc://localhost:2136 -d /local topic create /local/logstash_demo_topic
```

Setup plugin in Logstash pipeline config

To activate the plugin, add the `ydb_topic` block in the `output` section of the Logstash pipeline config. Additionally, add the `http` block in the `input` section for creating test messages via HTTP requests:

```
output {
  ydb_topic {
    connection_string => "grpc://localhost:2136/local" # YDB connection string
    topic_path => "/local/logstash_demo_topic"         # The topic name for writing
  }
}

input {
  http {
    port => 9876 # Any free port
  }
}
```

To apply these changes, restart Logstash.

Send a test message

Send a test message via the `http` plugin:

```
curl -H "content-type: application/json" -XPUT 'http://127.0.0.1:9876/http/ping' -d '{ "user" : "demo_user",
"message" : "demo message", "level": 4}'
```

The command returns `ok` if the message has been sent successfully.

Reading the message from the topic

Check that the plugin wrote the message to the topic successfully by reading this message via CLI:

```
ydb -e grpc://localhost:2136 -d /local topic consumer add --consumer logstash-consumer /local/logstash_demo_t
opic
ydb -e grpc://localhost:2136 -d /local topic read /local/logstash_demo_topic --consumer logstash-consumer --c
ommit true
```

The latter command will return the message content:

```
{"level":4,"message":"demo message","timestamp":1716470292640,"user":"demo_user"}
```

Importing table structures and data from JDBC data sources to YDB

Introduction

Table structures and data can be imported into YDB from data sources accessible via JDBC drivers using the JDBC import tool. This can be useful for migrating from other database management systems to YDB or just importing your real data to run some benchmarks on YDB.

Data import is performed using the following process:

1. The tool connects to the source database and determines the list of tables and custom SQL queries to be imported.
2. The structure of target YDB tables is generated and optionally saved as YQL script.
3. The target database is checked for the existence of the target tables. Missing tables are created, and already existing ones may be left as is or re-created.
4. Row data is imported by reading from the source database using the SELECT statements and written into the target YDB database using the Bulk Upsert mechanism.

All operations, including metadata extraction from the source database, table creation (and re-creation) in the target database, and row data import, are performed in parallel mode (thread-per-table), using multiple concurrent threads and multiple open connections to both source and target databases. The maximum degree of parallelism is configurable, although the number of concurrent operations can't exceed the number of imported tables or custom SQL queries.

Import tool installation

To run the import tool, JDK 8 or later is required, with the `java` executable available in the program search path. The tool has been built and tested using OpenJDK 8.

Import tool binary distribution is available on the Releases page. The import tool is provided as the ZIP archive, which needs to be unpacked into the local directory on the server where the tool is required to run.

The import tool distribution archive contains the configuration file examples as `*.xml` files, sample tool startup script `ydb-importer.sh`, and the executable code for the tool and its dependencies (including the YDB Java SDK) as `lib/*.jar` files.

Before running the import tool, the JDBC drivers for the source databases should be put (as `*.jar` files) into the `lib` subdirectory of the tool installation directory.

Using the import tool

The tool reads the XML configuration file on startup. When running the tool, the file name must be specified as a free command line argument. Settings in the configuration file define:

- source database type and connection preferences;
- YDB target database connection preferences;
- (optional) file name to save the generated YQL script with YDB target tables structure;
- the rules to filter source tables' names;
- the list of custom SQL queries to fetch data from the data source (can be used to define custom queries to get data from all or some of the tables);
- the rules to generate target tables' names based on the names of the source tables;
- the degree of parallelism (which determines the worker pool size, plus the connection pool sizes for both source and target databases).

The configuration file based on one of the provided samples needs to be prepared before running the import tool.

The example command to run the tool is provided in the ydb-importer.sh file, which can also be used to run the tool as shown below:

```
./ydb-importer.sh my-import-config.xml
```

Import tool limitations

The tested data sources include the following database management systems:

- PostgreSQL
- MySQL
- Oracle Database
- Microsoft SQL Server
- IBM Db2
- IBM Informix

Other data sources will likely work, too, as the tool uses the generic JDBC APIs to retrieve data and metadata.

Secondary indexes are not imported.

Some data types and table structures are known to be unsupported:

- the embedded tables for Oracle Database
- spatial data type for Microsoft SQL Server
- object data types for Informix

Handling tables without the primary key

Each YDB table must have a primary key. If a primary key (or at least a unique index) is defined on the source table, the tool creates the primary key for the target YDB table with the columns and order determined by the original primary key. When multiple unique indexes are defined on the source table, the tool prefers the index with the smallest number of columns.

In case the source table has no primary key and no unique indexes, primary key columns can be configured using the import settings in the configuration file as a sequence of `key-column` elements in the `table-ref` section (see below the example in the description of the configuration file format).

When no primary key is defined anywhere, the tool automatically adds the column `ydb_synth_key` to the target table and uses it as the primary key. The values of the synthetic primary key are computed as "SHA-256" hash code over the values of all row cells except the columns of the `BLOB` type.

If the input table contains several rows with completely identical values, the destination table will have only one row per each set of duplicate input rows. This also means that the tool cannot import the table in which all columns are of `BLOB` type.

Importing large objects (BLOB, XML)

For each BLOB field in the source database, the import tool creates an additional YDB target table (BLOB supplemental table) with the following schema:

```
CREATE TABLE `blob_table`(
    `id` Int64,
    `pos` Int32,
    `val` String,
    PRIMARY KEY(`id`, `pos`)
)
```

The name of the BLOB supplemental table is generated based on the `table-options` / `blob-name-format` setting in the configuration file.

Each BLOB field value is saved as a sequence of records in the BLOB supplemental table in YDB. Actual data is stored in the `val` field, storing no more than 64K bytes. The order of blocks stored is defined by the values of the `pos` column, containing the integer values `1..N`.

For each source BLOB value, a unique value of type `Int64` is generated and stored in the `id` field of the BLOB supplemental table. This identifier is also stored in the "main" target table in a field that has the same name as the BLOB field in the source table.

For PostgreSQL, working with the `EXTENSION lo` BLOBS may require extra permissions for the account used to connect to the data source. An alternative option is to enable the compatibility mode on the database level using the following statement:

```
ALTER DATABASE dbname SET lo_compat_privileges TO on;
```

Configuration file format

Sample configuration files:

- for PostgreSQL
- for MySQL
- for Oracle Database
- for Microsoft SQL Server
- for IBM Db2
- for IBM Informix

Below is the explanation of the configuration file structure:

```
<?xml version="1.0" encoding="UTF-8"?>
<ydb-importer>
    <workers>
        <!-- Number of worker threads (integer starting with 1).
             This setting also defines the maximum number of source and target database sessions.
         -->
        <pool size="4"/>
    </workers>
    <!-- Source database connection parameters.
         type - the required attribute defining the type of the data source
      -->
    <source type="generic|postgresql|mysql|oracle|mssql|db2|informix">
        <!-- JDBC driver class name to be used. Typical values:
              org.postgresql.Driver
              com.mysql.cj.jdbc.Driver
              org.mariadb.jdbc.Driver
              oracle.jdbc.driver.OracleDriver
              com.microsoft.sqlserver.jdbc.SQLServerDriver
              com.ibm.db2.jcc.DB2Driver
              com.informix.jdbc.IfxDriver
        -->
        <jdbc-class>driver-class-name</jdbc-class>
        <!-- JDBC driver URL. Value templates:
              jdbc:postgresql://hostname:5432/dbname
              jdbc:mysql://hostname:3306/dbname
              jdbc:mariadb://hostname:3306/dbname
              jdbc:oracle:thin:@//hostname:1521/serviceName
              jdbc:sqlserver://localhost;encrypt=true;trustServerCertificate=true;database=AdventureWorks202
2;
              jdbc:db2://localhost:50000/SAMPLE
              jdbc:informix-sqli://localhost:9088/stores_demo:INFORMIXSERVER=informix
        -->
        <jdbc-url>jdbc-url</jdbc-url>
        <username>username</username>
        <password>password</password>
    </source>
    <!-- Target YDB database connection parameters. -->
    <target type="ydb">
        <!-- If the following tag is defined, the tool will import
             The YQL script is used to generate YDB tables in the file specified.
             It can also be used without specifying the connection string,
             if the actual target schema creation is not required.
        -->
        <script-file>sample-database.yql.tmp</script-file>
        <!-- Connection string: protocol + endpoint + database. Typical values:
            grpcs://ydb.serverless.yandexcloud.net:2135?database=/ru-central1/b1gfvslmokutuvt2g019/etn63999hr
inbapmef6g
            grpcs://localhost:2135?database=/local
            grpc://localhost:2136?database=/Root/testdb
         -->
        <connection-string>ydb-connection-string</connection-string>
        <!-- Authentication mode:
          ENV      Configure authentication via environment variables
          NONE     Anonymous access, or static credentials in the connection string
          STATIC   Static credentials defined as login and password properties (see below)
          SAKEY    Service account key file authentication for YDB Managed Service
          METADATA Service account metadata authentication for YDB Managed Service
        -->
        <auth-mode>ENV</auth-mode>
        <!--
         For managed YDB in Yandex Cloud, authentication parameters can be specified
         in the environment variables, as specified in the documentation:
            https://ydb.tech/en/docs/reference/ydb-sdk/auth#env
         In case the Service Account authentication is used, either explicitly
         or through the YDB_SERVICE_ACCOUNT_KEY_FILE_CREDENTIALS env, the key file
         must be generated as written in the following document:
            https://yandex.cloud/en/docs/iam/operations/authorized-key/create
        -->
        <!-- Custom TLS certificates, if needed -->
        <tls-certificate-file>ca.crt</tls-certificate-file>
        <!-- For auth-mode: STATIC -->
        <static-login>username</static-login>
        <static-password>password</static-password>
        <!-- For auth-mode: SAKEY -->
        <sa-key-file>ydb-sa-keyfile.json</sa-key-file>
        <!-- Drop the already existing tables before loading the data -->
        <replace-existing>false</replace-existing>
        <!-- Should the tool actually load the data after creating tables? -->
        <load-data>true</load-data>
        <!-- Maximum rows per bulk upsert operation
             (used for writing into the main table) -->
        <max-batch-rows>1000</max-batch-rows>
        <!-- Maximum rows per blob bulk upsert operation
             (used for writing into the supplemental BLOB fields tables) -->
        <max-blob-rows>200</max-blob-rows>
    </target>
    <!-- Table name and structure conversion rules.
         Each rule is defined under a distinct name, and later referenced in the table mappings.
     -->
    <table-options name="default">
        <!--  Table name case conversion mode: ASIS (no changes, used by default), LOWER, UPPER. -->
```

```
        <case-mode>ASIS</case-mode>
        <!-- The template used to generate the full destination YDB table name,
             including the directory to put the table in.
             The values ${schema} and ${table} are used to substitute
             the schema and table name of the source table. -->
        <table-name-format>oraimp1/${schema}/${table}</table-name-format>
        <!-- The template used to generate the name of the supplemental table
             to store source BLOB field's data in YDB.
             The values ${schema}, ${table} and ${field}
             are used for source schema, table and BLOB field names. -->
        <blob-name-format>oraimp1/${schema}/${table}_${field}</blob-name-format>
        <!-- Date and timestamp data type values conversion mode.
             Possible values: DATE (use YDB Date datatype, default), INT, STR.
             DATE does not support input values before January, 1, 1970,
                 and there will be import errors for such values in the source
             INT saves date as 32-bit integer YYYYMMDD for dates,
                 and as a 64-bit milliseconds since epoch for timestamps.
             STR saves dates as character strings (Utf8) in format "YYYY-MM-DD",
                 and in "YYYY-MM-DD hh:mm:ss.xxx" for timestamps.
         -->
        <conv-date>INT</conv-date>
        <conv-timestamp>STR</conv-timestamp>
        <!-- If true, columns with unsupported types are skipped with warning,
             otherwise import error is generated, and the whole table is skipped. -->
        <skip-unknown-types>true</skip-unknown-types>
    </table-options>
    <!-- Table map filters the source tables and defines the conversion modes for them. -->
    <table-map options="default">
        <!-- Schemas to include, can be specified as regular expression or literal value -->
        <include-schemas regexp="true">.*</include-schemas>
        <!-- Schemas to exclude (of those included), as literal or regular expression -->
        <exclude-schemas>SOMESCHEMA</exclude-schemas>
        <!-- Particular tables can be included or excluded using the
             "include-tables" and "exclude-tables" tags,
             using literals or regular expressions as well. -->
    </table-map>
    <!-- Table reference may refer to a particular table in a particular schema
         and optionally specify the query to execute. The latter option allows to import
         virtual tables that do not actually exist on the data source. -->
    <table-ref options="default">
        <schema-name>ora$sys</schema-name>
        <table-name>all_tables</table-name>
        <!-- If the query text is defined, it is executed as shown. -->
        <query-text>SELECT * FROM all_tables</query-text>
        <!-- Primary key column names should be defined for the query result.  -->
        <key-column>OWNER</key-column>
        <key-column>TABLE_NAME</key-column>
    </table-ref>
</ydb-importer>
```

Importing table schemas and data from MySQL

Introduction

Migrating schemas and data from **MySQL** to YDB — including **large tables** whose size exceeds available RAM — is performed using the mysql2ydb utility.

The utility's goal is to get an exact one-to-one copy of the source database. Table and column names are preserved as in MySQL; data types are mapped to the nearest equivalents in YDB (`INT` → `Int32`, `VARCHAR` → `Text`, `AUTO_INCREMENT` → `BigSerial`, etc.). Since names are transferred unchanged, they must be valid identifiers in YDB (characters, length, reserved words). The result should be a YDB database that replicates the original structure and allows queries with minimal "translation" from MySQL.

Each data fragment is read from MySQL by a single bounded query `SELECT`, written to YDB in a batch (`BulkUpsert` or transactional `UPSERT`), and then freed from memory. The process repeats until the entire table is processed — no more than one batch is stored in memory at a time (no more than two with pipeline reading).

The import is performed in the following order:

1. The utility connects to MySQL and, based on the `information_schema` metadata, determines the list of tables and their structure.
2. Target tables with mapped data types are created in YDB.
3. Data is transferred in batches: reading from MySQL and writing to YDB.
4. After each batch is successfully written, the cursor position is saved to the state table — in case of failure, migration can be resumed from the last successful fragment.

MySQL schema mapping

When transferring the schema, mysql2ydb aims for **structural correspondence**: the same table and column names, indexes where YDB supports them, and types that preserve values without loss (unsigned integers remain unsigned, boolean types remain boolean, etc.).

The utility reads MySQL metadata from `information_schema` and generates YDB DDL directly. The main type mappings are:

MySQL type	Type in YDB
`INT`, `MEDIUMINT`, `SMALLINT`, `TINYINT`	`Int32`
`BIGINT`	`Int64`
`INT UNSIGNED`, `MEDIUMINT UNSIGNED`, `SMALLINT UNSIGNED`, `TINYINT UNSIGNED`	`Uint32`
`BIGINT UNSIGNED`	`Uint64`
`TINYINT(1)`	`Bool`
`FLOAT`	`Float`
`DOUBLE`, `REAL`	`Double`
`BIT`	`Uint64` (including `BIT(1)` — wrapped in `Uint64`, not in `Bool`)
`CHAR`, `VARCHAR`, `TEXT`, `MEDIUMTEXT`, `LONGTEXT`	`Text`
`ENUM`, `SET`, `JSON`	`Text`
`BINARY`, `VARBINARY`, `BLOB`, `MEDIUMBLOB`, `LONGBLOB`	`String` (bytes inline in the same column)
`DATE`	`Date`
`DATETIME`, `TIMESTAMP`	`Timestamp` — the value is stored as UTC. For `DATETIME` (a type without time zone), the interpretation depends on the `time_zone` MySQL setting during reading; keep this in mind when migrating historical data.
`DECIMAL(p, s)`, `NUMERIC(p, s)`	`Decimal(22, 9)` for all — the original `p` / `s` are not preserved; values that do not fit in 22 digits will be lost
`YEAR`	`Uint16`
Other types	`Text` (fallback)

Structural decisions

MySQL schema element	mysql2ydb decision
Table and column names	As in MySQL (`users`, `orders`, ...); must be valid YDB identifiers
`AUTO_INCREMENT`	`BigSerial` + `ALTER SEQUENCE … START WITH` from `TABLES.AUTO_INCREMENT`
Secondary `KEY` / `UNIQUE KEY`	`INDEX … GLOBAL ASYNC` / `GLOBAL UNIQUE SYNC` in `CREATE TABLE`
Table without `PRIMARY KEY`	Not supported when automatically creating the schema — see Tables without a primary key
Partitioning	Only `AUTO_PARTITIONING_BY_LOAD`

Secondary indexes

Non-unique MySQL keys become `INDEX … GLOBAL ASYNC`, unique ones (except the primary key) become `INDEX … GLOBAL UNIQUE SYNC`. Tables with synchronous unique indexes automatically switch to transactional `UPSERT` during data loading, because `BulkUpsert` only supports asynchronous indexes.

Examples

`AUTO_INCREMENT` — the MySQL column `id BIGINT AUTO_INCREMENT` becomes:

```
`id` BigSerial NOT NULL,
PRIMARY KEY (`id`)
```

After `CREATE TABLE`, if the value of `information_schema.TABLES.AUTO_INCREMENT` is known:

```
ALTER SEQUENCE `<db>/<table>/_serial_column_id` START WITH <next_value> RESTART
```

Tables without a primary key

In YDB, each table must have a `PRIMARY KEY`. mysql2ydb takes the key **only** from MySQL columns with `COLUMN_KEY = 'PRI'`; `UNIQUE KEY` indexes become secondary `GLOBAL UNIQUE SYNC`, but are **not** substituted for the primary key. If a table has no `PRIMARY KEY`, schema creation fails with an error (`PRIMARY KEY ()` — invalid DDL), and data transfer does not start.

Before migration, you need to set a key in MySQL for such tables, for example:

```
ALTER TABLE my_table ADD COLUMN id BIGINT AUTO_INCREMENT PRIMARY KEY FIRST;
```

or assign `PRIMARY KEY` to an existing column (or set of columns) if it is truly unique.

If you cannot add `PRIMARY KEY` in MySQL, but you can prepare the schema in YDB manually, create the table with the required key yourself and run the utility with the `-data-only` flag. Reading from MySQL without `PRIMARY KEY` in the metadata will go through `LIMIT/OFFSET`: on each page, MySQL rescans all previous rows, so migration time grows quadratically with table size — for large tables, it is better to add a key in MySQL beforehand. The key columns in YDB must be present among the MySQL columns.

If you need automatic import without a key in MySQL, consider YDB Importer — it adds a synthetic column `ydb_synth_key` (SHA-256 of the row). mysql2ydb does not create synthetic keys.

Efficient access to MySQL

The utility minimizes accesses to MySQL and limits the size of each query:

1. **Page-by-page reading by primary key** — `WHERE (pk…) > (?) ORDER BY pk LIMIT n`. Without full table scan into memory.
2. **Read → write pipeline** — one goroutine reads the next batch from MySQL while another writes the previous one to YDB. No more than two batches are in flight at the same time per table.
3. **Adaptive batch size** — the number of rows is limited by available RAM and the average row size from `information_schema`.
4. **Progress checkpoint** — after each successfully written batch, the cursor position and row counter are saved in the YDB service table; a restart continues from the last batch.

```
MySQL: SELECT batch N   →  BulkUpsert(batch N)   →  YDB
MySQL: SELECT batch N+1 →  BulkUpsert(batch N+1) →  YDB
...
```

Features

- **One-to-one schema copy** — original table and column names; mapping of MySQL types to the nearest YDB types (`AUTO_INCREMENT` → `BigSerial`, `UNSIGNED` → `Uint32` / `Uint64`, secondary indexes, `TINYINT(1)` → `Bool`; see the MySQL schema mapping section).
- **Schema creation** — tables in YDB are created from MySQL metadata (`information_schema`).
- **Fragment-by-fragment data migration**: the table is processed in fixed-size chunks; the data volume may exceed available RAM.
- **Upsert by key** — data is written via `BulkUpsert` or transactional `UPSERT`; re-running does not create duplicate rows.
- **Resumption** — progress for each table is stored in YDB; an interrupted migration can be resumed from the last batch.

Installation

Source code and build instructions are in the mysql-ydb-importer repository on GitHub.

Building requires Go version not lower than specified in `go.mod` of the repository:

```
git clone https://github.com/ydb-platform/mysql-ydb-importer.git
cd mysql-ydb-importer
go build -o mysql2ydb ./cmd/mysql2ydb
```

Usage procedure

MySQL connection parameters are read by default from the **~/.my.cnf** file (like the `mysql` client), section `[client]`. The `-mysql` flag overrides the configuration file.

Tables without primary key

Tables without `PRIMARY KEY` in MySQL **are not supported** during automatic schema creation. Before running, add a primary key in MySQL or prepare the schema manually and use `-data-only` (see the section Tables without a primary key).

Example `~/.my.cnf`:

```
[client]
user = myuser
password = mypass
host = localhost
port = 3306
database = mydb
```

If the server requires a secure connection (`require_secure_transport=ON`), add to `[client]`:

```
ssl-mode = REQUIRED
```

For a self-signed certificate (without verification):

```
ssl-mode = REQUIRED
ssl-verify = 0
```

Alternative option — `ssl=1` and `ssl-verify=0`.

Minimum startup when `~/.my.cnf` is present (only `-ydb` is required):

```
./mysql2ydb -ydb "grpc://localhost:2136"
```

With explicit MySQL DSN (ignores `~/.my.cnf`):

```
./mysql2ydb -mysql "user:$MYSQL_PASSWORD@tcp(localhost:3306)/mydb" -ydb "grpc://localhost:2136" -batch-size 1
0000
```

Command line flags

Flag	Description
`-mysql`	DSN MySQL (if specified, overrides `~/.my.cnf`)
`-ydb`	Endpoint YDB (required)
`-ydb-database`	Path to YDB database (default `local`)
`-schema-only`	Only create the schema, without data transfer
`-data-only`	Only transfer data (the schema in YDB must already exist — including one created manually)
`-batch-size`	Target batch size in rows (default 10,000)
`-max-chunk-rows`	Hard upper limit of rows in a batch (default 25,000)
`-parallel-tables`	Number of tables for parallel transfer (default 1)
`-tables`	Comma-separated list of tables (default – all)
`-force`	Migrate all tables from scratch, ignoring the saved state
`-force-recreate`	Delete all tables in YDB and recreate the schema from scratch

Examples

Schema only:

```
./mysql2ydb -mysql "..." -ydb "grpc://localhost:2136" -schema-only
```

Only data (after schema creation):

```
./mysql2ydb -mysql "..." -ydb "grpc://localhost:2136" -data-only -batch-size 5000
```

Selected tables:

```
./mysql2ydb -mysql "..." -ydb "grpc://localhost:2136" -tables "users,orders"
```

Fragment-based reading

- For tables with a **primary key** in MySQL, cursor-based pagination is used: `WHERE (pk > ?) ORDER BY pk LIMIT batch_size`. No more than one batch is kept in memory at a time.
- If there is no `PRIMARY KEY` in MySQL, but the schema in YDB has already been created manually (mode `-data-only`), `LIMIT batch_size OFFSET offset` is applied — see the section Tables without a primary key.

Writing to YDB

By default, data is written via `BulkUpsert`. For tables with synchronous unique indexes, the utility automatically switches to transactional `UPSERT`, since `BulkUpsert` only supports asynchronous indexes.

Queries to YDB are marked as idempotent, so the SDK automatically retries them on network failures. The absence of duplicates when restarting the migration is ensured by overwriting rows by key and saving progress in a service table (see the Features section, the "Resumption" item).

Comparison with YDB Importer

There are other tools for loading data into YDB. YDB Importer is a universal JDBC importer for PostgreSQL, Oracle, SQL Server, and other sources: XML configuration, parallel import, partitioning configuration.

mysql2ydb solves a more specific task — one-to-one migration of a MySQL database using a single binary file, without JVM. For migration only from MySQL with large tables, `~/.my.cnf` and the `-ydb` flag are sufficient; progress is saved in the service table YDB.

	YDB Importer	**mysql2ydb**
Runtime	Java + JDBC drivers + XML configuration	One binary file in Go, native MySQL protocol
Scope	Multiple JDBC sources	Only MySQL
Default batch size	1,000 rows (`max-batch-rows`)	10,000 rows (`-batch-size`), with auto-tuning
Large tables	Parallel ranges, partition buffers	Cursor-based paginated reading, batch size based on RAM
Resumption after failure	Re-running the import	Checkpoint per batch in the service table YDB
Setting	JDBC JAR files, XML configuration	`~/.my.cnf` and two flags

YDB Importer is designed for importing from many JDBC sources into a **configurable** YDB structure (`table-name-format` , `blob-name-format` , date conversion modes, optional synthetic keys). Below are the practical differences when importing the same MySQL database with two tools:

MySQL feature	mysql2ydb (one-to-one copy)	ydb-importer
Table names	As in MySQL (`users` , `orders` , …)	Rename by pattern, e.g., `mysql1/${schema}/${table}` → `mysql1/mydb/users` (configuration example)
Column names	As in MySQL	Sanitization: spaces, `.` , `/` , `` ` `` → `_`
`AUTO_INCREMENT`	`BigSerial` + `ALTER SEQUENCE … START WITH` from `TABLES.AUTO_INCREMENT`	Regular `Int32` / `Int64` ; no `BigSerial` or sequence reset
`INT UNSIGNED` , `BIGINT UNSIGNED` , …	`Uint32` / `Uint64`	JDBC maps integers to signed `Int32` / `Int64`
`TINYINT(1)`	`Bool`	`TINYINT` → `Int32` (`BOOLEAN` → `Bool`)
`BIT`	`Uint64`	`Bool` (JDBC `Types.BIT`)
Secondary `KEY` / `UNIQUE KEY`	`INDEX … GLOBAL ASYNC` / `GLOBAL UNIQUE SYNC` in `CREATE TABLE`	Only `PRIMARY KEY` in DDL; secondary indexes are not created
`ENUM` , `SET` , `JSON`	`Text`	`Text` (similar)
`BLOB` / `BINARY`	Same column, value inline in `String` (bytes)	Column becomes `Int64` (blob identifier); data is moved to a **separate table** `${schema}/${table}_${field}` with `(id, pos, val)` rows in 64 KB blocks
`TEXT` / `CLOB` (large text)	Inline `Text` in the main table	Optionally a separate CLOB table (32 K character blocks) or inline `Text` depending on settings
Table **without a primary key**	**Not supported** — `CREATE TABLE` fails with an error; add `PRIMARY KEY` in MySQL before migration	A column `ydb_synth_key Text` is added as PK (SHA-256 of the row); **duplicates are collapsed** into one row
`DATE`	`Date`	`Date32` by default (`conv-date=DATE_NEW`)
`DATETIME` / `TIMESTAMP`	`Timestamp`	`Datetime64` / `Timestamp64` by default
`TIME`	`Text` (fallback)	`Int32` (seconds since midnight)
`DECIMAL(p,s)`	`Decimal(22, 9)` for all	`Decimal(p,s)` when `allow-custom-decimal=true`
`YEAR`	`Uint16`	Not covered in MySQL type tests
Partitioning	Only `AUTO_PARTITIONING_BY_LOAD`	`PARTITION_AT_KEYS` , splitting by source partitions, `HASH` for column store, etc.

Working with BLOBs

MySQL table `attachments (id INT, data MEDIUMBLOB)` :

	Column `data` in the main table	Where bytes are stored
mysql2ydb	`data String`	In the same row
ydb-importer	`data Int64` (reference)	Separate table `…/attachments_data` with chunked rows

With mysql2ydb, you can perform `SELECT data FROM attachments WHERE id = 1` the same way as in MySQL. With ydb-importer, you need to join the main table with an additional blob table.

Integration of dbt with YDB

Introduction

dbt (data build tool) is a tool for data transformation in analytical data platforms, designed to organize data model development using software engineering practices. It covers the transformation (T) stage in ETL pipelines and enables structured modeling of data logic — from raw data to data marts — with support for testing, documentation, and data lineage, providing end-to-end traceability of data from source to final model.

Models in dbt are defined uniformly as `SELECT` statements, simplifying their maintenance and composability. The tool handles their materialization in the target system and tracks dependencies between models, including the evolution of data across transformation stages.

To integrate dbt with YDB, the dbt-ydb connector is used. It enables connecting to YDB as a target platform and supports model materialization as tables and views, incremental data processing, loading test datasets (seeds), as well as running data tests and generating documentation.

This section describes the connector's capabilities and provides steps to set up and start using it.

> **Warning**
>
> The dbt-ydb connector is in the Preview stage and does not currently support all dbt features. The sections below list the supported features and known limitations.

Features

Models and Their Materialization

A core concept in dbt is a data model. A model is essentially a SQL query that can reference any data source in your data warehouse, including other models. The dbt-ydb connector supports the following approaches to materializing models in YDB:

1. **View** — stored as a YDB view.
2. **Table** — stored as a table in YDB and re-created by dbt on each model update.

   The dbt-ydb connector allows you to specify the following table parameters using model configuration:

Parameter	Required	Default Value	Description
primary_key	Yes		Primary key of the table
store_type	No	`row`	Table type. `row` for row-oriented table or `column` for column-oriented table
auto_partitioning_by_size	No		Automatic partitioning by size
auto_partitioning_partition_size_mb	No		Partition size threshold
ttl	No		Time-To-Live rule

   Example of a model materialized as a table based on another model (using ref).
   Configured with a primary key, TTL, and automatic partitioning by size.

   ```
   {{ config(
      primary_key='id, created_at',
      store_type='row',
      auto_partitioning_by_size='ENABLED',
      auto_partitioning_partition_size_mb=256,
      ttl='Interval("P30D") on created_at'
   ) }}

   select
      id,
      name,
      created_at
   from {{ ref('source_table') }}
   ```

3. Incremental model — created as a table inside YDB, but instead of being recreated, it is updated with changed and new rows when refreshed by dbt.

   The dbt-ydb connector supports the same parameters as for table materialization, plus unique parameters for the incremental model:

Parameter	Required	Default Value	Description
incremental_strategy	No	`MERGE`	Incremental materialization strategy. The `MERGE` strategy is supported, using the YDB `UPSERT` operation. `APPEND` strategy support is under development.

> **Note**
>
> Another materialization type, ephemeral model, is not currently supported by the connector.

Snapshots

The snapshot mechanism is not currently supported by dbt-ydb.

Seeds (CSV-based reference/test data)

The dbt-ydb connector supports dbt seeds to upload reference and test data from CSV files into your project and use them in other models.

Data Testing

dbt-ydb supports standard dbt data tests, as well as singular tests within the capabilities of YQL.

Documentation Generation

dbt-ydb supports generating documentation from dbt projects for YDB.

Getting Started

Requirements

To start working with dbt on YDB, you will need:

- Python 3.10+;
- dbt Core 1.8+;
- An existing YDB cluster (a single-node installation from the quickstart is sufficient).

> **Note**
>
> dbt Fusion 2.0 is not supported at this time.

Installation

To install dbt-ydb, run:

```
pip install dbt-ydb
```

Connecting dbt to a YDB Cluster

dbt connects to YDB via the dbt-ydb connector using the standard way for YDB. To connect successfully, specify the endpoint, database path, and authentication parameters in the dbt profiles file.

Example profile file with possible authentication options and default values (in square brackets):

```
profile_name:
target: dev
outputs:
   dev:
      type: ydb
      host: [localhost] # YDB host
      port: [2136] # YDB port
      database: [/local] # YDB database
      schema: [<empty string>] # Optional subfolder for DBT models
      secure: [False] # If enabled, grpcs protocol will be used
      root_certificates_path: [<empty string>] # Optional path to root certificates file

      # Static Credentials
      username: [<empty string>]
      password: [<empty string>]

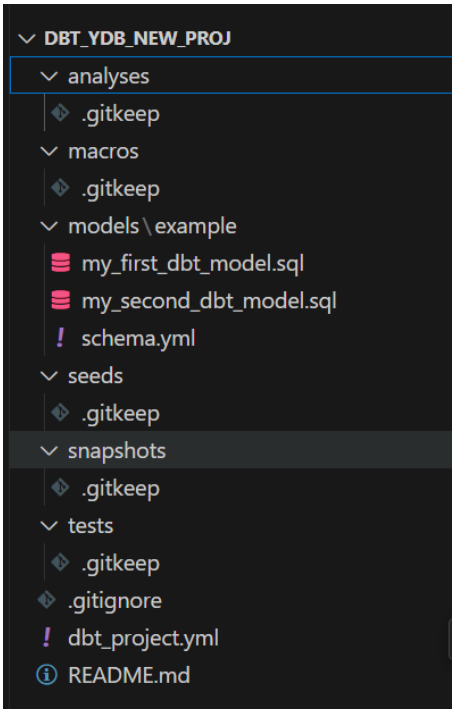
      # Access Token Credentials
      token: [<empty string>]

      # Service Account Credentials
      service_account_credentials_file: [<empty string>]
```

Creating a Project from Scratch via dbt init

1. Initialize a project:

   ```
   dbt init
   ```



2. Follow dbt's interactive prompts to select the dbt-ydb connector and authentication settings for your YDB cluster.
3. As a result, your project directory will be created along with a dbt profiles file in your home directory, containing a new connection to YDB:

   ```
   ~/.dbt/profiles.yml
   ```

4. Run `dbt debug` to verify the connection:

   ```
   dbt debug
   ```

5. Inside your project directory, you will find the following structure:

6. Adapt the model `my_first_dbt_model`.

   Currently, dbt does not support customizing the auto-generated example per connector. Therefore, to run this model with dbt-ydb, you need to update it as follows:

```
/*
   Welcome to your first dbt model!
   Did you know that you can also configure models directly within SQL files?
   This will override configurations stated in dbt_project.yml

   Try changing "table" to "view" below
*/

{{ config(materialized='table', primary_key='id') }}

select *
from (
   select 1 as id
   union all
   select null as id
)
```

7. Now you can run your project:

```
dbt run
```

Running the Example Project

The dbt-ydb connector comes with an example you can use to quickly test dbt functionality with YDB.

1. Clone the repository:

```
git clone https://github.com/ydb-platform/dbt-ydb.git
cd dbt-ydb/examples/jaffle_shop
```

2. Configure the connection profile in the `profiles.yml` file. For a single-node installation from the quickstart, the file should look like this:

```
profile_name:
   target: dev
   outputs:
      dev:
      type: ydb
      host: localhost # YDB host
      port: 2136 # YDB port
      database: /local # YDB database
      schema: jaffle_shop
```

3. Verify the connection:

```
dbt debug
```

4. Load test data (via seeds):

   This command will load CSV files from `data/` into `raw_*` tables in YDB.

```
dbt seed
```

5. Run models:

   This will create tables and views based on the project's example models.

   ```
   dbt run
   ```

6. Test model data:

   This will run standard data tests described in the example — such as checks for `null`, allowed values lists, and others.

   ```
   dbt test
   ```

7. Generate documentation and start a local web server to view it:

   The project documentation will be available in your browser at http://localhost:8080.

   ```
   dbt docs generate
   dbt docs serve --port 8080
   ```

Next Steps

You can find the official dbt documentation here.
Additionally, you can explore the connector's source code and contribute to its development in the public dbt-ydb repository on GitHub.

Migrating YDB data schemas with the Flyway migration tool

Introduction

Flyway is an open-source database migration tool. It strongly favors simplicity and convention over configuration. It has extensions for various database management systems (DBMS), including YDB.

Install

To use Flyway with YDB in a Java / Kotlin application or a Gradle / Maven plugin, you need to add dependencies for the Flyway core, the Flyway extension for YDB, and the YDB JDBC Driver:

Maven

```
<!-- Set actual versions -->
<dependency>
    <groupId>org.flywaydb</groupId>
    <artifactId>flyway-core</artifactId>
    <version>${flyway.core.version}</version>
</dependency>

<dependency>
    <groupId>tech.ydb.jdbc</groupId>
    <artifactId>ydb-jdbc-driver</artifactId>
    <version>${ydb.jdbc.version}</version>
</dependency>

<dependency>
    <groupId>tech.ydb.dialects</groupId>
    <artifactId>flyway-ydb-dialect</artifactId>
    <version>${flyway.ydb.dialect.version}</version>
</dependency>
```

Gradle

```
dependencies {
    // Set actual versions
    implementation "org.flywaydb:flyway-core:$flywayCoreVersion"
    implementation "tech.ydb.dialects:flyway-ydb-dialect:$flywayYdbDialecVersion"
    implementation "tech.ydb.jdbc:ydb-jdbc-driver:$ydbJdbcVersion"
}
```

To work with YDB via Flyway CLI, you need to install the `flyway` utility itself using one of the recommended methods.

Then the utility must be extended with the YDB dialect and the JDBC driver:

```
# install flyway
# cd $(which flyway) // prepare this command for your environment

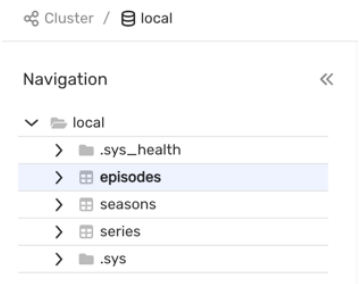
cd libexec
# set actual versions of .jar files

cd drivers && curl -L -o ydb-jdbc-driver-shaded-2.1.0.jar https://repo.maven.apache.org/maven2/tech/ydb/jdbc/
ydb-jdbc-driver-shaded/2.1.0/ydb-jdbc-driver-shaded-2.1.0.jar

cd ..

cd lib && curl -L -o flyway-ydb-dialect.jar https://repo.maven.apache.org/maven2/tech/ydb/dialects/flyway-ydb
-dialect/1.0.0-RC0/flyway-ydb-dialect-1.0.0-RC0.jar
```

Note



Flyway Desktop is currently not supported.

Migration management using Flyway

baseline

Command baseline initializes Flyway in an existing database, excluding all migrations up to and including the `baselineVersion`.

Suppose we have an existing project with the current database schema:

Let's write down our existing migrations as follows:

```
db/migration:
  V1__create_series.sql
  V2__create_seasons.sql
  V3__create_episodes.sql
```

Contents of SQL files:

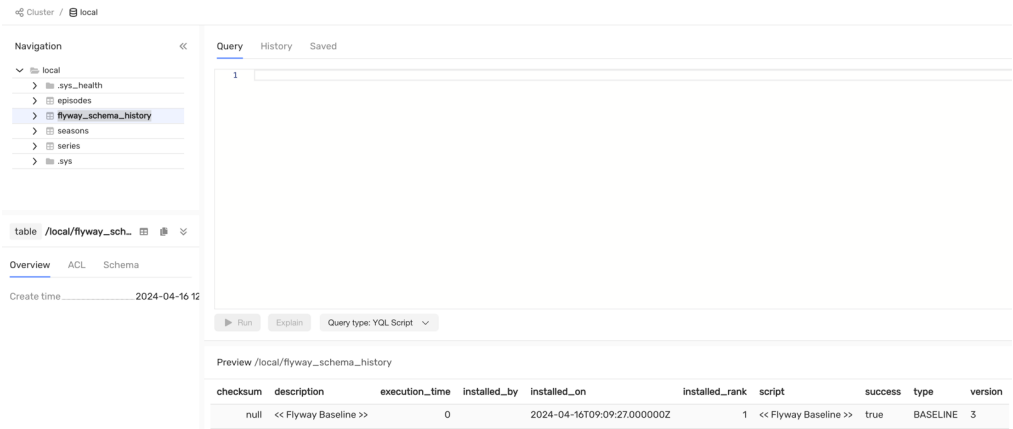
V1__create_series.sql

```
CREATE TABLE series -- series is the table name.
(                           -- Must be unique within the folder.
    series_id    Int64,
    title        Text,
    series_info  Text,
    release_date Int64,
    PRIMARY KEY (series_id) -- The primary key is a column or
    -- combination of columns that uniquely identifies
    -- each table row (contains only
    -- non-repeating values). A table can have
    -- only one primary key. For every table
    -- in YDB, the primary key is required.
);
```

V2__create_seasons.sql

```
CREATE TABLE seasons
(
    series_id Uint64,
    season_id Uint64,
    title Utf8,
    first_aired Uint64,
    last_aired Uint64,
    PRIMARY KEY (series_id, season_id)
);
```

V3__create_episodes.sql



```
CREATE TABLE episodes
(
    series_id Uint64,
    season_id Uint64,
    episode_id Uint64,
    title Utf8,
    air_date Uint64,
    PRIMARY KEY (series_id, season_id, episode_id)
);
```

Set `baselineVersion = 3`, then run the following command:

```
flyway -url=jdbc:ydb:grpc://localhost:2136/local -locations=db/migration -baselineVersion=3 baseline
```

> **Note**
>
> All examples use a Docker container, which does not require any additional authentication parameters.
>
> You can see how to connect to YDB in the next section.

As a result, a table named `flyway_schema_history` will be created, and it will contain a `baseline` record:

migrate

Command migrate evolves the database schema to the latest version. Flyway will create the schema history table automatically if it doesn't exist.

Let's add the migration of data downloads to the previous example:

```
db/migration:
  V1__create_series.sql
  V2__create_seasons.sql
  V3__create_episodes.sql
  V4__load_data.sql
```

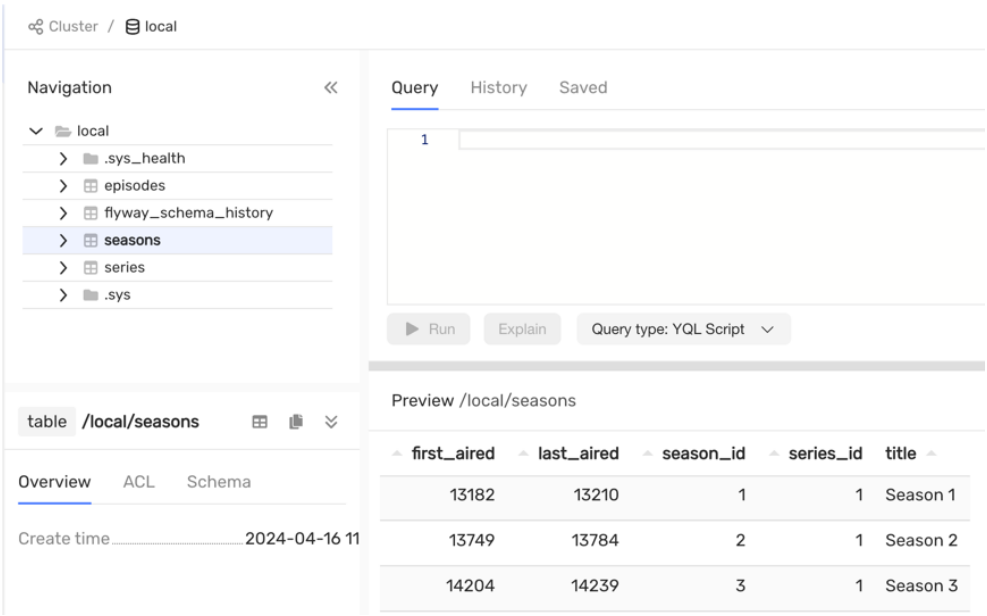
The contents of `V4__load_data.sql`

```
INSERT INTO series (series_id, title, release_date, series_info)
VALUES

    -- By default, numeric literals have type Int32
    -- if the value is within the range.
    -- Otherwise, they automatically expand to Int64.
    (1,
     "IT Crowd",
     CAST(Date ("2006-02-03") AS Uint64), -- CAST converts one datatype into another.
        -- You can convert a string
        -- literal into a primitive literal.
        -- The Date() function converts a string
        -- literal in ISO 8601 format into a date.

     "The IT Crowd is a British sitcom produced by Channel 4, written by Graham Linehan, produced by Ash
Atalla and starring Chris O'Dowd, Richard Ayoade, Katherine Parkinson, and Matt Berry."),
    (2,
     "Silicon Valley",
     CAST(Date ("2014-04-06") AS Uint64),
     "Silicon Valley is an American comedy television series created by Mike Judge, John Altschuler and D
ave Krinsky. The series focuses on five young men who founded a startup company in Silicon Valley.")
;

INSERT INTO seasons (series_id, season_id, title, first_aired, last_aired)
VALUES (1, 1, "Season 1", CAST(Date ("2006-02-03") AS Uint64), CAST(Date ("2006-03-03") AS Uint64)),
       (1, 2, "Season 2", CAST(Date ("2007-08-24") AS Uint64), CAST(Date ("2007-09-28") AS Uint64)),
       (1, 3, "Season 3", CAST(Date ("2008-11-21") AS Uint64), CAST(Date ("2008-12-26") AS Uint64)),
       (1, 4, "Season 4", CAST(Date ("2010-06-25") AS Uint64), CAST(Date ("2010-07-30") AS Uint64)),
       (2, 1, "Season 1", CAST(Date ("2014-04-06") AS Uint64), CAST(Date ("2014-06-01") AS Uint64)),
       (2, 2, "Season 2", CAST(Date ("2015-04-12") AS Uint64), CAST(Date ("2015-06-14") AS Uint64)),
       (2, 3, "Season 3", CAST(Date ("2016-04-24") AS Uint64), CAST(Date ("2016-06-26") AS Uint64)),
       (2, 4, "Season 4", CAST(Date ("2017-04-23") AS Uint64), CAST(Date ("2017-06-25") AS Uint64)),
       (2, 5, "Season 5", CAST(Date ("2018-03-25") AS Uint64), CAST(Date ("2018-05-13") AS Uint64))
;



INSERT INTO episodes (series_id, season_id, episode_id, title, air_date)
VALUES (1, 1, 1, "Yesterday's Jam", CAST(Date ("2006-02-03") AS Uint64)),
       (1, 1, 2, "Calamity Jen", CAST(Date ("2006-02-03") AS Uint64)),
       (1, 1, 3, "Fifty-Fifty", CAST(Date ("2006-02-10") AS Uint64)),
       (1, 1, 4, "The Red Door", CAST(Date ("2006-02-17") AS Uint64)),
       (1, 1, 5, "The Haunting of Bill Crouse", CAST(Date ("2006-02-24") AS Uint64)),
       (1, 1, 6, "Aunt Irma Visits", CAST(Date ("2006-03-03") AS Uint64)),
       (1, 2, 1, "The Work Outing", CAST(Date ("2006-08-24") AS Uint64)),
       (1, 2, 2, "Return of the Golden Child", CAST(Date ("2007-08-31") AS Uint64)),
       (1, 2, 3, "Moss and the German", CAST(Date ("2007-09-07") AS Uint64)),
       (1, 2, 4, "The Dinner Party", CAST(Date ("2007-09-14") AS Uint64)),
       (1, 2, 5, "Smoke and Mirrors", CAST(Date ("2007-09-21") AS Uint64)),
       (1, 2, 6, "Men Without Women", CAST(Date ("2007-09-28") AS Uint64)),
       (1, 3, 1, "From Hell", CAST(Date ("2008-11-21") AS Uint64)),
       (1, 3, 2, "Are We Not Men?", CAST(Date ("2008-11-28") AS Uint64)),
       (1, 3, 3, "Tramps Like Us", CAST(Date ("2008-12-05") AS Uint64)),
       (1, 3, 4, "The Speech", CAST(Date ("2008-12-12") AS Uint64)),
       (1, 3, 5, "Friendface", CAST(Date ("2008-12-19") AS Uint64)),
       (1, 3, 6, "Calendar Geeks", CAST(Date ("2008-12-26") AS Uint64)),
       (1, 4, 1, "Jen The Fredo", CAST(Date ("2010-06-25") AS Uint64)),
       (1, 4, 2, "The Final Countdown", CAST(Date ("2010-07-02") AS Uint64)),
       (1, 4, 3, "Something Happened", CAST(Date ("2010-07-09") AS Uint64)),
       (1, 4, 4, "Italian For Beginners", CAST(Date ("2010-07-16") AS Uint64)),
       (1, 4, 5, "Bad Boys", CAST(Date ("2010-07-23") AS Uint64)),
       (1, 4, 6, "Reynholm vs Reynholm", CAST(Date ("2010-07-30") AS Uint64)),
       (2, 1, 1, "Minimum Viable Product", CAST(Date ("2014-04-06") AS Uint64)),
       (2, 1, 2, "The Cap Table", CAST(Date ("2014-04-13") AS Uint64)),
       (2, 1, 3, "Articles of Incorporation", CAST(Date ("2014-04-20") AS Uint64)),
       (2, 1, 4, "Fiduciary Duties", CAST(Date ("2014-04-27") AS Uint64)),
       (2, 1, 5, "Signaling Risk", CAST(Date ("2014-05-04") AS Uint64)),
       (2, 1, 6, "Third Party Insourcing", CAST(Date ("2014-05-11") AS Uint64)),
       (2, 1, 7, "Proof of Concept", CAST(Date ("2014-05-18") AS Uint64)),
       (2, 1, 8, "Optimal Tip-to-Tip Efficiency", CAST(Date ("2014-06-01") AS Uint64)),
       (2, 2, 1, "Sand Hill Shuffle", CAST(Date ("2015-04-12") AS Uint64)),
       (2, 2, 2, "Runaway Devaluation", CAST(Date ("2015-04-19") AS Uint64)),
       (2, 2, 3, "Bad Money", CAST(Date ("2015-04-26") AS Uint64)),
       (2, 2, 4, "The Lady", CAST(Date ("2015-05-03") AS Uint64)),
       (2, 2, 5, "Server Space", CAST(Date ("2015-05-10") AS Uint64)),
       (2, 2, 6, "Homicide", CAST(Date ("2015-05-17") AS Uint64)),
       (2, 2, 7, "Adult Content", CAST(Date ("2015-05-24") AS Uint64)),
       (2, 2, 8, "White Hat/Black Hat", CAST(Date ("2015-05-31") AS Uint64)),
       (2, 2, 9, "Binding Arbitration", CAST(Date ("2015-06-07") AS Uint64)),
       (2, 2, 10, "Two Days of the Condor", CAST(Date ("2015-06-14") AS Uint64)),
       (2, 3, 1, "Founder Friendly", CAST(Date ("2016-04-24") AS Uint64)),
       (2, 3, 2, "Two in the Box", CAST(Date ("2016-05-01") AS Uint64)),
       (2, 3, 3, "Meinertzhagen's Haversack", CAST(Date ("2016-05-08") AS Uint64)),
       (2, 3, 4, "Maleant Data Systems Solutions", CAST(Date ("2016-05-15") AS Uint64)),
       (2, 3, 5, "The Empty Chair", CAST(Date ("2016-05-22") AS Uint64)),
       (2, 3, 6, "Bachmanity Insanity", CAST(Date ("2016-05-29") AS Uint64)),
       (2, 3, 7, "To Build a Better Beta", CAST(Date ("2016-06-05") AS Uint64)),
       (2, 3, 8, "Bachman's Earnings Over-Ride", CAST(Date ("2016-06-12") AS Uint64)),
       (2, 3, 9, "Daily Active Users", CAST(Date ("2016-06-19") AS Uint64)),
       (2, 3, 10, "The Uptick", CAST(Date ("2016-06-26") AS Uint64)),
       (2, 4, 1, "Success Failure", CAST(Date ("2017-04-23") AS Uint64)),
```

```
        (2, 4, 2, "Terms of Service", CAST(Date ("2017-04-30") AS Uint64)),
        (2, 4, 3, "Intellectual Property", CAST(Date ("2017-05-07") AS Uint64)),
        (2, 4, 4, "Teambuilding Exercise", CAST(Date ("2017-05-14") AS Uint64)),
        (2, 4, 5, "The Blood Boy", CAST(Date ("2017-05-21") AS Uint64)),
        (2, 4, 6, "Customer Service", CAST(Date ("2017-05-28") AS Uint64)),
        (2, 4, 7, "The Patent Troll", CAST(Date ("2017-06-04") AS Uint64)),
        (2, 4, 8, "The Keenan Vortex", CAST(Date ("2017-06-11") AS Uint64)),
        (2, 4, 9, "Hooli-Con", CAST(Date ("2017-06-18") AS Uint64)),
        (2, 4, 10, "Server Error", CAST(Date ("2017-06-25") AS Uint64)),
        (2, 5, 1, "Grow Fast or Die Slow", CAST(Date ("2018-03-25") AS Uint64)),
        (2, 5, 2, "Reorientation", CAST(Date ("2018-04-01") AS Uint64)),
        (2, 5, 3, "Chief Operating Officer", CAST(Date ("2018-04-08") AS Uint64)),
        (2, 5, 4, "Tech Evangelist", CAST(Date ("2018-04-15") AS Uint64)),
        (2, 5, 5, "Facial Recognition", CAST(Date ("2018-04-22") AS Uint64)),
        (2, 5, 6, "Artificial Emotional Intelligence", CAST(Date ("2018-04-29") AS Uint64)),
        (2, 5, 7, "Initial Coin Offering", CAST(Date ("2018-05-06") AS Uint64)),
        (2, 5, 8, "Fifty-One Percent", CAST(Date ("2018-05-13") AS Uint64));
```

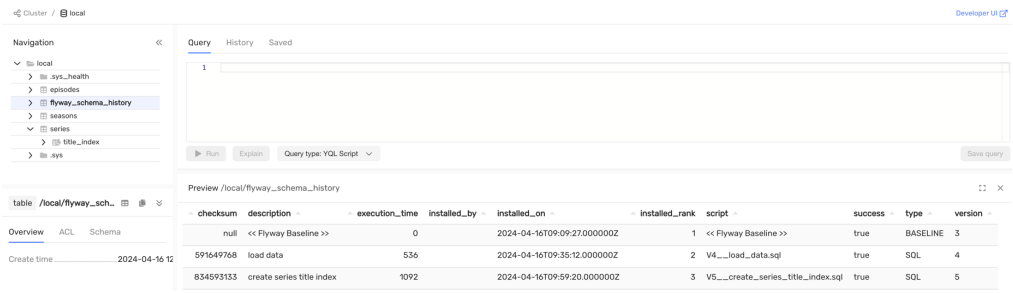
Let's apply the latest migration using the following command:

```
flyway -url=jdbc:ydb:grpc://localhost:2136/local -locations=db/migration migrate
```

As a result, `series`, `season`, and `episode` tables will be created and filled with data:

Then, we evolve the schema by adding a secondary index to the `series` table:

```
db/migration:
  V1__create_series.sql
  V2__create_seasons.sql
  V3__create_episodes.sql
  V4__load_data.sql
  V5__create_series_title_index.sql
```



The contents of `V5__create_series_title_index.sql`

```
ALTER TABLE `series` ADD INDEX `title_index` GLOBAL ON (`title`);
```

Let's apply the latest migration using the following command:

```
flyway -url=jdbc:ydb:grpc://localhost:2136/local -locations=db/migration migrate
```

As a result, a secondary index for the `series` table will be created:

info

Command info prints the details and status information about all the migrations.

Let's add another migration that renames the previously added secondary index:

```
db/migration:
  V1__create_series.sql
  V2__create_seasons.sql
  V3__create_episodes.sql
  V4__load_data.sql
  V5__create_series_title_index.sql
  V6__rename_series_title_index.sql
```

The contents of `V6__rename_series_title_index.sql`

```
ALTER TABLE `series` RENAME INDEX `title_index` TO `title_index_new`;
```

The result of executing the `flyway -url=jdbc:ydb:grpc://localhost:2136/local -locations=db/migration info` will provide detailed information about the status of the migrations:

```
+-----------+---------+---------------------------+----------+---------------------+--------------------+----
------+
| Category  | Version | Description               | Type     | Installed On        | State              | Und
oable |
+-----------+---------+---------------------------+----------+---------------------+--------------------+----
------+
| Versioned | 1       | create series             | SQL      |                     | Below Baseline     | No
|
| Versioned | 2       | create seasons            | SQL      |                     | Below Baseline     | No
|
| Versioned | 3       | create episodes           | SQL      |                     | Ignored (Baseline) | No
|
|           | 3       | << Flyway Baseline >>     | BASELINE | 2024-04-16 12:09:27 | Baseline           | No
|
| Versioned | 4       | load data                 | SQL      | 2024-04-16 12:35:12 | Success            | No
|
| Versioned | 5       | create series title index | SQL      | 2024-04-16 12:59:20 | Success            | No
|
| Versioned | 6       | rename series title index | SQL      |                     | Pending            | No
|
+-----------+---------+---------------------------+----------+---------------------+--------------------+----
------+
```

validate

Command validate validates the applied migrations against the available ones.

After applying the `flyway -url=jdbc:ydb:grpc://localhost:2136/local -locations=db/migration validate` command with current migrations, the logs will show that the latest migration was not applied to our database:

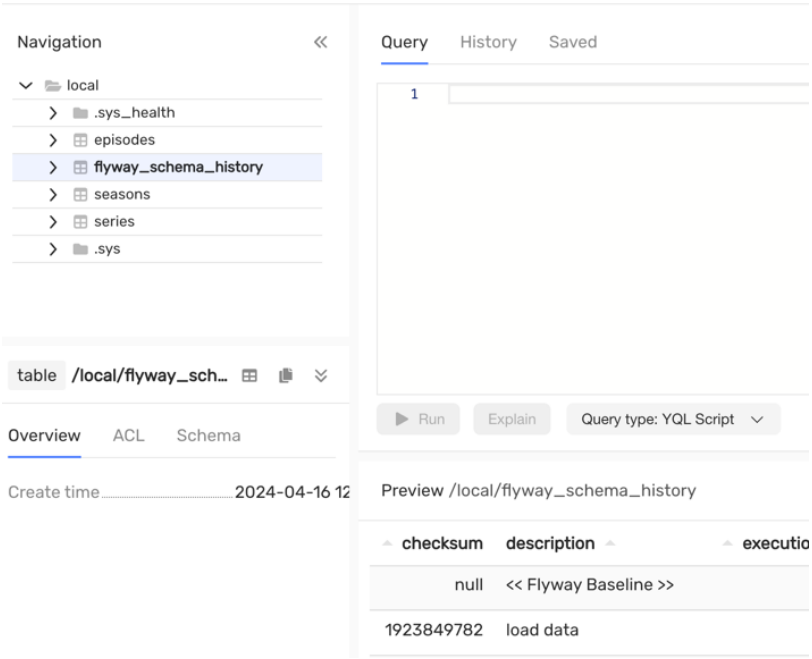
```
ERROR: Validate failed: Migrations have failed validation
Detected resolved migration not applied to database: 6.
To fix this error, either run migrate, or set -ignoreMigrationPatterns='*:pending'.
```

Let's apply this error by executing `flyaway .. migrate` again. The validation will now be successful, and the secondary index will be renamed.

Next, we will modify the file of the previously applied migration `V4__load_date.sql` by deleting comments from the SQL script.

After executing the validation command, we got a logical error because the `checksum` differed in the modified migration:

```
ERROR: Validate failed: Migrations have failed validation
Migration checksum mismatch for migration version 4
-> Applied to database : 591649768
-> Resolved locally    : 1923849782
```



repair

Command repair tries to fix the identified errors and discrepancies from the database schema history table.

Fix the problem with different `checksum`'s by running the following command:

```
flyway -url=jdbc:ydb:grpc://localhost:2136/local -locations=db/migration repair
```

The result will be an update to the `checksum` column in the `flyway_schema_history` table for the migration entry `V4__load_data.sql`:

After restoring the log table, validation is successful.

Also, using the `repair` command, you can delete a failed DDL script.

clean

Command clean drops all objects in the configured schemas.

> **Warning**
>
> Unlike other database management systems, YDB does not have a concept of `SCHEMA`. Thus, the `clean` command **drops all the user tables** in a given database.

Let's delete all the tables in our database using the following command:

```
flyway -url=jdbc:ydb:grpc://localhost:2136/local -locations=db/migration -cleanDisabled=false clean
```

The result will be an empty database:

Data schema versioning and migration in YDB using "goose"

Introduction

Goose is an open-source tool that helps to version the data schema in the database and manage migrations between these versions. Goose supports many different database management systems, including YDB. Goose uses migration files and stores the state of migrations directly in the database in a special table.

Install goose

Goose installation options are described in its documentation.

Launch arguments goose

After installation, the `goose` command line utility can be called:

```
$ goose <DB> <CONNECTION_STRING> <COMMAND> <COMMAND_ARGUMENTS>
```

Where:

- `<DB>` - database engine, for YDB you should write `goose ydb`
- `<CONNECTION_STRING>` - database connection string.
- `<COMMAND>` - the command to be executed. A complete list of commands is available in the built-in help (`goose help`).
- `<COMMAND_ARGUMENTS>` - command arguments.

YDB connection string

To connect to YDB you should use a connection string like:

```
<protocol>://<host>:<port>/<database_path>?go_query_mode=scripting&go_fake_tx=scripting&go_query_bind=declar
e,numeric
```

Where:

- `<protocol>` - connection protocol (`grpc` for an unsecured connection or `grpcs` for a secure TLS connection). The secure connection requires certificates. You should declare certificates like this: `export YDB_SSL_ROOT_CERTIFICATES_FILE=/path/to/ydb/certs/CA.pem` .
- `<host>` - hostname for connecting to YDB cluster.
- `<port>` - port for connecting to YDB cluster.
- `<database_path>` - database in the YDB cluster.
- `go_query_mode=scripting` - special `scripting` mode for executing queries by default in the YDB driver. In this mode, all requests from goose are sent to the YDB `scripting` service, which allows processing of both DDL and DML SQL statements.
- `go_fake_tx=scripting` - support for transaction emulation in query execution mode through the YDB `scripting` service. The fact is that in YDB, executing `DDL` `SQL` statements in a transaction is impossible (or incurs significant overhead). In particular, the `scripting` service does not allow interactive transactions (with explicit `Begin` + `Commit` / `Rollback`). Accordingly, the transaction emulation mode does not actually do anything (`noop`) on the `Begin` + `Commit` / `Rollback` calls from `goose` . This trick can, in rare cases, cause an individual migration step to end up in an intermediate state. The YDB team is working on a new `query` service that should eliminate this risk.
- `go_query_bind=declare,numeric` - support for bindings of auto-inference of YQL types from query parameters (`declare`) and support for bindings of numbered parameters (`numeric`). YQL is a strongly typed language that requires you to explicitly specify the types of query parameters in the body of the `SQL` query itself using the special `DECLARE` statement. Also, YQL only supports named query parameters (for example, `$my_arg`), while the goose core generates SQL queries with numbered parameters (`$1` , `$2` , etc.) . The `declare` and `numeric` bindings modify the original queries from `goose` at the YDB driver level.

If connecting to a local YDB docker container, the connection string could look like:

```
grpc://localhost:2136/local?go_query_mode=scripting&go_fake_tx=scripting&go_query_bind=declare,numeric
```

Let's store this connection string to an environment variable to re-use it later:

```
export YDB_CONNECTION_STRING="grpc://localhost:2136/local?go_query_mode=scripting&go_fake_tx=scripting&go_que
ry_bind=declare,numeric"
```

Further examples of calling `goose` commands will contain exactly this connection string.

Directory with migration files

Let's create a migrations directory and then all `goose` commands should be executed in this directory:

```
$ mkdir migrations && cd migrations
```

Managing migrations using goose

Creating migration files and applying to database

The migration file can be generated using the `goose create` command:

```
$ goose ydb $YDB_CONNECTION_STRING create 00001_create_first_table sql
2024/01/12 11:52:29 Created new file: 20240112115229_00001_create_first_table.sql
```

This means that the tool has created a new migration file `<timestamp>_00001_create_table_users.sql` :

```
$ ls
20231215052248_00001_create_table_users.sql
```

After executing the `goose create` command, a migration file `<timestamp>_00001_create_table_users.sql` will be created with the following content :

```
-- +goose Up
-- +goose StatementBegin
SELECT 'up SQL query';
-- +goose StatementEnd

-- +goose Down
-- +goose StatementBegin
SELECT 'down SQL query';
-- +goose StatementEnd
```

This migration file structure helps keep the instructions that lead to the next version of the database in context. It is also easy, without unnecessary distractions, to write instructions that roll back a database change.

The migration file consists of two sections:

1. `+goose Up` is an area where we can record the migration steps.
2. `+goose Down` is an area where we can write queries to revert changes of the `+goose Up` steps.

Goose carefully inserted placeholder queries:

```
SELECT 'up SQL query';
```

And

```
SELECT 'down SQL query';
```

So that we can replace them with the real migration SQL queries for change the schema for the YDB database, which is accessible through the corresponding connection string.

Let's edit the migration file `<timestamp>_00001_create_table_users.sql` so that when applying the migration we create a table with necessary schema, and when rolling back the migration we delete the created table:

```
-- +goose Up
-- +goose StatementBegin
CREATE TABLE users (
     id Uint64,
     username Text,
     created_at Timestamp,
     PRIMARY KEY (id)
);
-- +goose StatementEnd

-- +goose Down
-- +goose StatementBegin
DROP TABLE users;
-- +goose StatementEnd
```

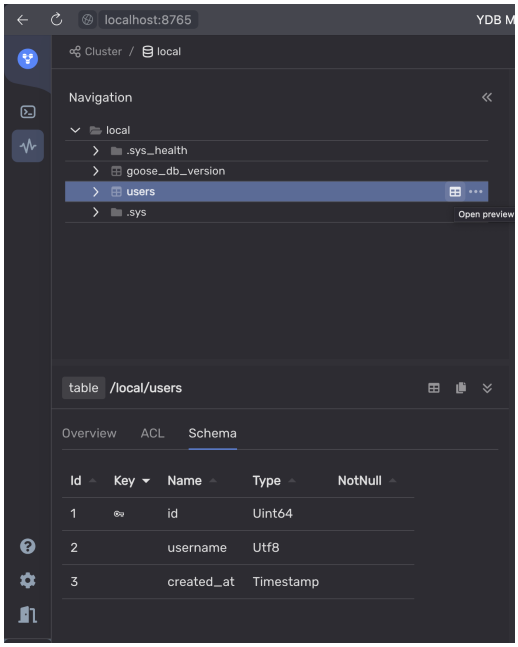
We can check status of migrations:

```
$ goose ydb $YDB_CONNECTION_STRING status
2024/01/12 11:53:50     Applied At                  Migration
2024/01/12 11:53:50     =======================================
2024/01/12 11:53:50     Pending                  -- 20240112115229_00001_create_first_table.sql
```

Status `Pending` of migration means that migration has not been applied yet. You can apply such migrations with commands `goose up` or `goose up-by-one`.

Let's apply migration using `goose up`:

```
$ goose ydb $YDB_CONNECTION_STRING up
2024/01/12 11:55:18 OK   20240112115229_00001_create_first_table.sql (93.58ms)
2024/01/12 11:55:18 goose: successfully migrated database to version: 20240112115229
```



Let's check the status of migration through `goose status`:

```
$ goose ydb $YDB_CONNECTION_STRING status
2024/01/12 11:56:00     Applied At                  Migration
2024/01/12 11:56:00     =======================================
2024/01/12 11:56:00     Fri Jan 12 11:55:18 2024 -- 20240112115229_00001_create_first_table.sql
```

Status `Pending` changed to timestamp `Fri Jan 12 11:55:18 2024` - this means that migration applied.

There are alternative options to see the applied changes:

Using YDB UI on `http://localhost:8765`

Using YDB CLI

```
$ ydb -e grpc://localhost:2136 -d /local scheme describe users
<table> users

Columns:
┌────────────┬────────────┬────────┬─────┐
| Name       | Type       | Family | Key |
├────────────┼────────────┼────────┼─────┤
| id         | Uint64?    |        | K0  |
| username   | Utf8?      |        |     |
| created_at | Timestamp? |        |     |
└────────────┴────────────┴────────┴─────┘

Storage settings:
Store large values in "external blobs": false

Column families:
┌─────────┬──────┬─────────────┬──────────────────┐
| Name    | Data | Compression | Keep in memory |
├─────────┼──────┼─────────────┼──────────────────┤
| default |      | None        |                  |
└─────────┴──────┴─────────────┴──────────────────┘

Auto partitioning settings:
Partitioning by size: true
Partitioning by load: false
Preferred partition size (Mb): 2048
Min partitions count: 1
```

Let's make the second migration that adds a column `password_hash` to the `users` table:

```
$ goose ydb $YDB_CONNECTION_STRING create 00002_add_column_password_hash_into_table_users sql
2024/01/12 12:00:57 Created new file: 20240112120057_00002_add_column_password_hash_into_table_users.sql
```

Let's edit the migration file `<timestamp>_00002_add_column_password_hash_into_table_users.sql`:

```
-- +goose Up
-- +goose StatementBegin
ALTER TABLE users ADD COLUMN password_hash Text;
-- +goose StatementEnd

-- +goose Down
-- +goose StatementBegin
ALTER TABLE users DROP COLUMN password_hash;
-- +goose StatementEnd
```

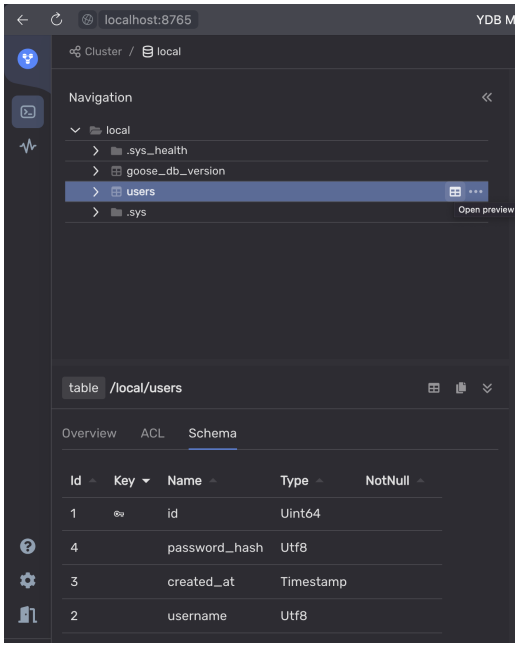
We can check the migration statuses again:

```
$ goose ydb $YDB_CONNECTION_STRING status
2024/01/12 12:02:40     Applied At                  Migration
2024/01/12 12:02:40     =======================================
2024/01/12 12:02:40     Fri Jan 12 11:55:18 2024 -- 20240112115229_00001_create_first_table.sql
2024/01/12 12:02:40     Pending                  -- 20240112120057_00002_add_column_password_hash_into_table_
users.sql
```

Now we see the first migration in applied status and the second in pending status.

Let's apply the second migration using `goose up-by-one`:

```
$ goose ydb $YDB_CONNECTION_STRING up-by-one
2024/01/12 12:04:56 OK   20240112120057_00002_add_column_password_hash_into_table_users.sql (59.93ms)
```



Let's check the migration status through `goose status`:

```
$ goose ydb $YDB_CONNECTION_STRING status
2024/01/12 12:05:17     Applied At                  Migration
2024/01/12 12:05:17     =======================================
2024/01/12 12:05:17     Fri Jan 12 11:55:18 2024 -- 20240112115229_00001_create_first_table.sql
2024/01/12 12:05:17     Fri Jan 12 12:04:56 2024 -- 20240112120057_00002_add_column_password_hash_into_table_
users.sql
```

Both migration are fully applied.

Let's use the same methods to see the new changes:

Using YDB UI on `http://localhost:8765`

Using YDB CLI

```
$ ydb -e grpc://localhost:2136 -d /local scheme describe users
<table> users

Columns:
┌───────────────┬──────────────┬────────┬─────┐
| Name          | Type         | Family | Key |
├───────────────┼──────────────┼────────┼─────┤
| id            | Uint64?      |        | K0  |
| username      | Utf8?        |        |     |
| created_at    | Timestamp?   |        |     |
| password_hash | Utf8?        |        |     |
└───────────────┴──────────────┴────────┴─────┘

Storage settings:
Store large values in "external blobs": false

Column families:
┌─────────┬──────┬─────────────┬──────────────────┐
| Name    | Data | Compression | Keep in memory |
├─────────┼──────┼─────────────┼──────────────────┤
| default |      | None        |                  |
└─────────┴──────┴─────────────┴──────────────────┘

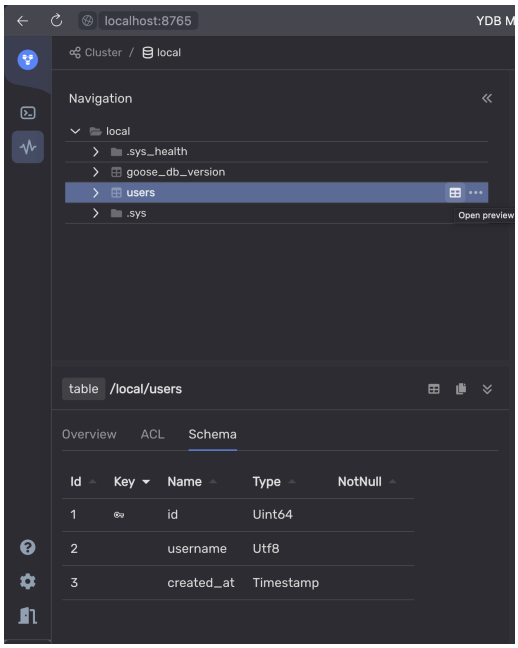
Auto partitioning settings:
Partitioning by size: true
Partitioning by load: false
Preferred partition size (Mb): 2048
Min partitions count: 1
```

All subsequent migration files should be created in the same way.

Downgrading migrations

Let's downgrade (revert) the latest migration using `goose down`:

```
$ goose ydb $YDB_CONNECTION_STRING down
2024/01/12 13:07:18 OK   20240112120057_00002_add_column_password_hash_into_table_users.sql (43ms)
```



Let's check the migration statuses through `goose status`:

```
$ goose ydb $YDB_CONNECTION_STRING status
2024/01/12 13:07:36     Applied At                  Migration
2024/01/12 13:07:36     =======================================
2024/01/12 13:07:36     Fri Jan 12 11:55:18 2024 -- 20240112115229_00001_create_first_table.sql
2024/01/12 13:07:36     Pending                  -- 20240112120057_00002_add_column_password_hash_into_table_
users.sql
```

Status `Fri Jan 12 12:04:56 2024` changed to `Pending` - this means that the latest migration is no longer applied.

Let's check the changes again:

Using YDB UI on `http://localhost:8765`

Using YDB CLI

```
$ ydb -e grpc://localhost:2136 -d /local scheme describe users
<table> users

Columns:
┌────────────┬────────────┬────────┬─────┐
| Name       | Type       | Family | Key |
├────────────┼────────────┼────────┼─────┤
| id         | Uint64?    |        | K0  |
| username   | Utf8?      |        |     |
| created_at | Timestamp? |        |     |
└────────────┴────────────┴────────┴─────┘

Storage settings:
Store large values in "external blobs": false

Column families:
┌─────────┬──────┬─────────────┬──────────────────┐
| Name    | Data | Compression | Keep in memory |
├─────────┼──────┼─────────────┼──────────────────┤
| default |      | None        |                  |
└─────────┴──────┴─────────────┴──────────────────┘

Auto partitioning settings:
Partitioning by size: true
Partitioning by load: false
Preferred partition size (Mb): 2048
Min partitions count: 1
```

Short list of "goose" commands

The `goose` utility allows you to manage migrations via the command line:

- `goose status` - view the status of applying migrations. For example, `goose ydb $YDB_CONNECTION_STRING status`.
- `goose up` - apply all known migrations. For example, `goose ydb $YDB_CONNECTION_STRING up`.
- `goose up-by-one` - apply exactly one “next” migration. For example, `goose ydb $YDB_CONNECTION_STRING up-by-one`.
- `goose redo` - re-apply the latest migration. For example, `goose ydb $YDB_CONNECTION_STRING redo`.
- `goose down` - rollback the last migration. For example, `goose ydb $YDB_CONNECTION_STRING down`.

- `goose reset` - rollback all migrations. For example, `goose ydb $YDB_CONNECTION_STRING reset`.

> **Warning**
>
> Be careful: the `goose reset` command will revert all your migrations using your statements in blocks `+goose Down`. In many cases it might lead to all data in the database being erased. Make sure you regularly do backups and check that they can be restored to minimize impact of this risk.

Migrating YDB data schemas with the Liquibase migration tool

Introduction

Liquibase is an open-source library for tracking, managing, and applying changes to database schemas. It is extended with dialects for different database management systems (DBMS), including YDB.

Dialect is the main component in the Liquibase framework, which assists in creating SQL queries for a database, considering the specific features of a given DBMS.

Features of the YDB Dialect

Liquibase's main functionality is the abstract description of database schemas in a `.xml`, `.json`, or `.yaml` format. This ensures portability when switching between different DBMSs.

The YDB dialect supports the following basic constructs in the standard migration description (changeset).

Creating a table

The `createTable` changeset is responsible for creating a table. The descriptions of types from the SQL standard are mapped to primitive types in YDB. For example, the `bigint` type will be converted to `Int64`.

> **Note**
>
> You can also explicitly specify the original type name, such as `Int32`, `Json`, `JsonDocument`, `Bytes`, or `Interval`. However, in this case, the schema won't be portable.

Table of comparison of Liquibase types descriptions with YDB types:

Liquibase types	YDB type
`boolean`, `java.sql.Types.BOOLEAN`, `java.lang.Boolean`, `bit`, `bool`	`Bool`
`blob`, `longblob`, `longvarbinary`, `String`, `java.sql.Types.BLOB`, `java.sql.Types.LONGBLOB`, `java.sql.Types.LONGVARBINARY`, `java.sql.Types.VARBINARY`, `java.sql.Types.BINARY`, `varbinary`, `binary`, `image`, `tinyblob`, `mediumblob`, `long binary`, `long varbinary`	`Bytes` (synonym `String`)
`java.sql.Types.DATE`, `smalldatetime`, `date`	`Date`
`decimal`, `java.sql.Types.DECIMAL`, `java.math.BigDecimal`	`Decimal(22,9)`
`double`, `java.sql.Types.DOUBLE`, `java.lang.Double`	`Double`
`float`, `java.sql.Types.FLOAT`, `java.lang.Float`, `real`, `java.sql.Types.REAL`	`Float`
`int`, `integer`, `java.sql.Types.INTEGER`, `java.lang.Integer`, `int4`, `int32`	`Int32`
`bigint`, `java.sql.Types.BIGINT`, `java.math.BigInteger`, `java.lang.Long`, `integer8`, `bigserial`, `long`	`Int64`
`java.sql.Types.SMALLINT`, `int2`, `smallserial`, `smallint`	`Int16`
`java.sql.Types.TINYINT`, `tinyint`	`Int8`
`char`, `java.sql.Types.CHAR`, `bpchar`, `character`, `nchar`, `java.sql.Types.NCHAR`, `nchar2`, `text`, `varchar`, `java.sql.Types.VARCHAR`, `java.lang.String`, `varchar2`, `character varying`, `nvarchar`, `java.sql.Types.NVARCHAR`, `nvarchar2`, `national`, `clob`, `longvarchar`, `longtext`, `java.sql.Types.LONGVARCHAR`, `java.sql.Types.CLOB`, `nclob`, `longnvarchar`, `ntext`, `java.sql.Types.LONGNVARCHAR`, `java.sql.Types.NCLOB`, `tinytext`, `mediumtext`, `long varchar`, `long nvarchar`	`Text` (synonym `Utf8`)
`timestamp`, `java.sql.Types.TIMESTAMP`, `java.sql.Timestamp`	`Timestamp`
`datetime`, `time`, `java.sql.Types.TIME`, `java.sql.Time`	`Datetime`

> **Warning**
>
> In YDB, the `Timestamp` data type stores dates with microsecond precision. The `java.sql.Timestamp` or `java.time.Instant` store timestamps with nanosecond precision, so you should be aware of this when using these data types.
>
> The type names are case insensitive.

The `dropTable` changeset - delete a table. For example: `<dropTable tableName="episodes"/>`

Changing the table structure

`addColumn` - add a column to a table. For example:

xml

```
<addColumn tableName="seasons">
    <column name="is_deleted" type="bool"/>
</addColumn>
```

json

```
"changes": [
    {
      "addColumn": {
        "tableName": "seasons",
        "columns": [
          {
            "column": {
              "name": "is_deleted",
              "type": "bool"
            }
          }
        ]
      }
    }
  ]
```

yaml

```
changes:
- addColumn:
    tableName: seasons
    columns:
    - column:
        name: is_deleted
        type: bool
```

`createIndex` - create a secondary index. For example:

xml

```
<createIndex tableName="episodes" indexName="episodes_index">
    <column name="title"/>
</createIndex>
```

json

```
"changes": [
    {
      "createIndex": {
        "tableName": "episodes",
        "indexName": "episodes_index",
        "columns": {
          "column": {
            "name": "title"
          }
        }
      }
    }
```

yaml

```
changes:
- createIndex:
    tableName: episodes
    indexName: episodes_index
    columns:
    - column:
        name: title
```

Warning

YDB doesn't support unique secondary indexes.

Note

Asynchronous indexes should be created using native SQL migrations.

`dropIndex` - drop a secondary index. For example:

xml

```
<dropIndex tableName="series" indexName="series_index"/>
```

json

```
"changes": [
  {
    "dropIndex": {
      "tableName": "series",
      "indexName": "series_index"
    }
  }
]
```

yaml

```
changes:
- dropIndex:
    tableName: series
    indexName: series_index
```

Ingesting data into a table

`loadData`, `loadUpdateData` - upload data from a `CSV` file into a table. `loadUpdateData` loads data using the UPSERT INTO command.

`insert` is a changeset that performs a single insert into a table using the INSERT INTO command. For example:

xml

```
<insert tableName="episodes">
    <column name="series_id" valueNumeric="1"/>
    <column name="season_id" valueNumeric="1"/>
    <column name="episode_id" valueNumeric="1"/>
    <column name="title" value="Yesterday's Jam"/>
    <column name="air_date" valueDate="2023-04-03T08:46:23.456"/>
</insert>
```

json

```
"changes": [
  {
    "insert": {
      "tableName": "episodes",
      "columns": [
        {
          "column": {
            "name": "series_id",
            "valueNumeric": "1"
          }
        },
        {
          "column": {
            "name": "season_id",
            "valueNumeric": "1"
          }
        },
        {
          "column": {
            "name": "episode_id",
            "valueNumeric": "1"
          }
        },
        {
          "column": {
            "name": "title",
            "value": "Yesterday's Jam"
          }
        },
        {
          "column": {
            "name": "air_date",
            "valueDate": "2023-04-03T08:46:23.456"
          }
        }
      ]
    }
  }
]
```

yaml

```yaml
changes:
- insert:
    tableName: episodes
    columns:
      - column:
          name: series_id
          valueNumeric: 1
      - column:
          name: season_id
          valueNumeric: 1
      - column:
          name: episode_id
          valueNumeric: 1
      - column:
          name: title
          value: Yesterday's Jam
      - column:
          name: air_date
          valueDate: 2023-04-03T08:46:23.456
```

You can also specify any value in the `value` field. Data from the `value` field in `insert` changeset or `CSV` files will be automatically converted to the required types, taking into account strict typing in YDB.

The type formatting table to load into the table:

YDB type	Description format
`Bool`	`true` or `false`
`Int8`, `Int16`, `Int32`, `Int64`	A signed integer
`Uint8`, `Uint16`, `Uint32`, `Uint64`	An unsigned integer
`Text`, `Bytes`, `Json`, `JsonDocument`	Represent as text
`Float`, `Double`, `Decimal(22, 9)`	A real number
`Interval`	ISO-8601, corresponds to the `java.time.Duration` in Java.
`Date`	Pattern `YYYY-MM-DD` calendar date from standard ISO-8601
`Datetime`	Pattern `YYYY-MM-DDThh:mm:ss`, timezone will be set to `UTC`
`Timestamp`	The timestamp from the ISO-8601 standard corresponds to the `java.time.Instant` in Java, timezone will be set to `UTC` (precision in microseconds - `Timestamp` type YDB restriction)

Example `CSV` file:

```
id,bool,bigint,smallint,tinyint,float,double,decimal,uint8,uint16,uint32,uint64,text,binary,json,jsondocumen
t,date,datetime,timestamp,interval
2,true,123123,13000,112,1.123,1.123123,1.123123,12,13,14,15,kurdyukov-kir,binary,{"asd": "asd"},{"asd": "as
d"},2014-04-06,2023-09-16T12:30,2023-07-31T17:00:00.00Z,PT10S
```

Warning

To understand which SQL statements YDB can perform and what are the restrictions on data types, read the documentation for the query language YQL.

Note

It is important to note that custom YQL instructions can be applied via native SQL queries.

How to use it?

There are two ways:

Programmatically from Java / Kotlin applications

The project's README describes how to use it from Java or Kotlin in detail. There is also an example of a Spring Boot application using it.

Liquibase CLI

First, you need to install Liquibase itself using one of the recommended methods. Then you need to place the `.jar` archives of YDB JDBC driver and Liquibase YDB dialect into the `internal/lib` folder.

```
# $(which liquibase)
cd ./internal/lib/

# you may need to sudo
# set actual versions of .jar files
curl -L -o ydb-jdbc-driver.jar https://repo.maven.apache.org/maven2/tech/ydb/jdbc/ydb-jdbc-driver-shaded/2.0.
7/ydb-jdbc-driver-shaded-2.0.7.jar
curl -L -o liquibase-ydb-dialect.jar https://repo.maven.apache.org/maven2/tech/ydb/dialects/liquibase-ydb-dia
lect/1.0.0/liquibase-ydb-dialect-1.0.0.jar
```

For a more detailed description, see the Manual library management in Liquibase documentation.

Now the `liquibase` command line utility can be used with YDB.

Liquibase usage scenarios

Initializing Liquibase on an empty YDB cluster

The main command is `liquibase update`, which applies migrations if the current schema in YDB lags behind the user-defined description.

Let's apply this changeset to an empty database:

```
<?xml version="1.0" encoding="UTF-8"?>
<databaseChangeLog
        xmlns="http://www.liquibase.org/xml/ns/dbchangelog"
        xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://www.liquibase.org/xml/ns/dbchangelog
                    http://www.liquibase.org/xml/ns/dbchangelog/dbchangelog-3.8.xsd">

    <changeSet id="episodes" author="kurdyukov-kir">
        <comment>Table episodes.</comment>

        <createTable tableName="episodes">
            <column name="series_id" type="bigint">
                <constraints primaryKey="true"/>
            </column>
            <column name="season_id" type="bigint">
                <constraints primaryKey="true"/>
            </column>
            <column name="episode_id" type="bigint">
                <constraints primaryKey="true"/>
            </column>

            <column name="title" type="text"/>
            <column name="air_date" type="timestamp"/>
        </createTable>
        <rollback>
            <dropTable tableName="episodes"/>
        </rollback>
    </changeSet>
    <changeSet id="index_episodes_title" author="kurdyukov-kir">
        <createIndex tableName="episodes" indexName="index_episodes_title">
            <column name="title"/>
        </createIndex>
    </changeSet>
</databaseChangeLog>
```

After executing the `liquibase update` command, Liquibase will print the following log:

```
UPDATE SUMMARY
Run:                          2
Previously run:               0
Filtered out:                 0
-------------------------------
Total change sets:            2

Liquibase: Update has been successful. Rows affected: 2
Liquibase command 'update' was executed successfully.
```

After applying migrations, the data schema now looks like this:

You can see that Liquibase has created two service tables: `DATABASECHANGELOG`, which is the migration log, and `DATABASECHANGELOGLOCK`, which is a table for acquiring a distributed lock.

Example contents of the `DATABASECHANGELOG` table:

AUTHOR	COMMENTS	CONTEXTS	DATEEXECUTED	DEPLOYMENT_ID	DESCRIPTION	EXECTYPE	FILENAME
kurdyukov-kir	Table episodes.		12:53:27	1544007500	createTable tableName=episodes	EXECUTED	migration/episodes.xml
kurdyukov-kir	""		12:53:28	1544007500	createIndex indexName=index_episodes_title, tableName=episodes	EXECUTED	migration/episodes.xml

Database schema evolution

Let's say we need to create a YDB topic and turn off the param `AUTO_PARTITIONING_BY_SIZE` of the table. This can be done with a native SQL script:

```
--liquibase formatted sql

--changeset kurdyukov-kir:create-a-topic
CREATE TOPIC `my_topic` (
    CONSUMER my_consumer
) WITH (
     retention_period = Interval('P1D')
);

--changeset kurdyukov-kir:auto-partitioning-disabled
ALTER TABLE episodes SET (AUTO_PARTITIONING_BY_SIZE = DISABLED);
```

Also, let's add a new column `is_deleted` and remove the `index_episodes_title` index:

```
<changeSet id="alter-episodes" author="kurdyukov-kir">
    <comment>Alter table episodes.</comment>

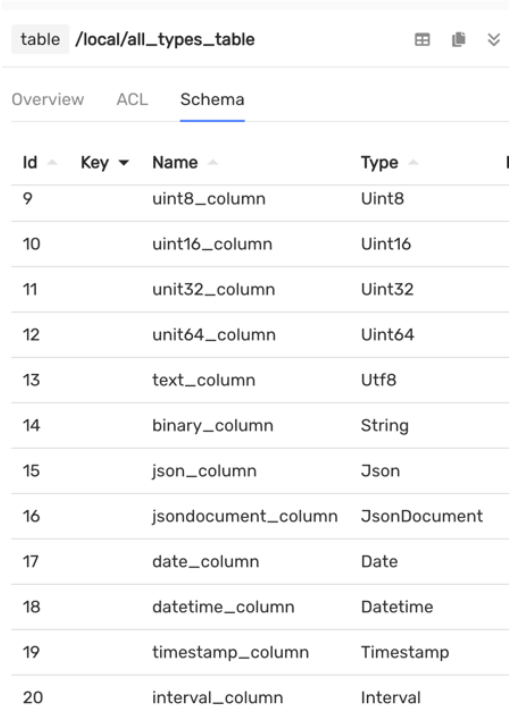
    <dropIndex tableName="episodes" indexName="index_episodes_title"/>

    <addColumn tableName="episodes">
        <column name="is_deleted" type="bool"/>
    </addColumn>
</changeSet>
<include file="/migration/sql/yql.sql" relativeToChangelogFile="true"/>
```

After executing `liquibase update`, the database schema will be successfully updated with all of these changes:

```
UPDATE SUMMARY
Run:                          3
Previously run:               2
Filtered out:                 0
-------------------------------
Total change sets:            5

Liquibase: Update has been successful. Rows affected: 3
Liquibase command 'update' was executed successfully.
```



The result will be deleting the index, adding the `is_deleted` column, disabling the auto partitioning setting, and creating a topic:

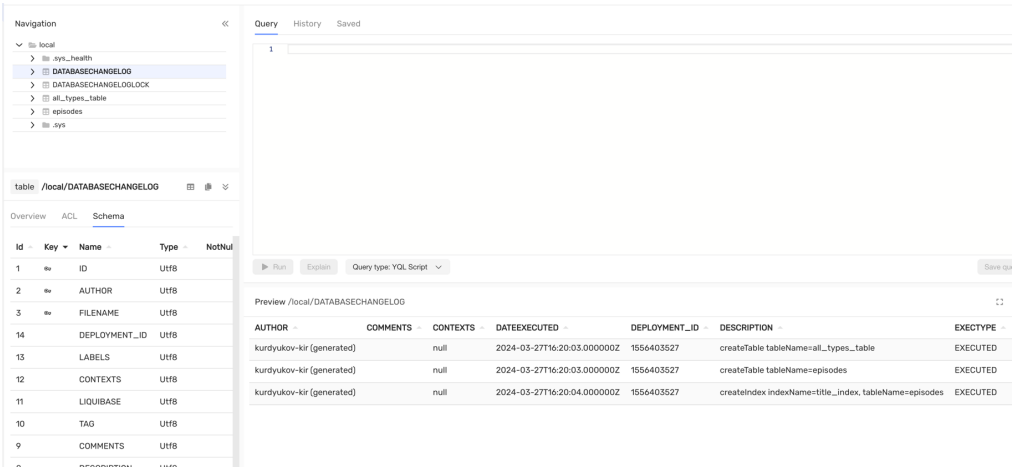
Initializing liquibase in a project with a non-empty data schema

Let's suppose there's an existing project with the following database schema:

Id	Key	Name	Type
9		uint8_column	Uint8
10		uint16_column	Uint16
11		unit32_column	Uint32
12		unit64_column	Uint64
13		text_column	Utf8
14		binary_column	String
15		json_column	Json
16		jsondocument_column	JsonDocument
17		date_column	Date
18		datetime_column	Datetime
19		timestamp_column	Timestamp
20		interval_column	Interval

In this case to start using Liquibase, you need to run:

```
liquibase generate-changelog --changelog-file=changelog.xml
```



The contents of the generated changelog.xml:

```
<changeSet author="kurdyukov-kir (generated)" id="1711556283305-1">
    <createTable tableName="all_types_table">
        <column name="id" type="INT32">
            <constraints nullable="false" primaryKey="true"/>
        </column>
        <column name="bool_column" type="BOOL"/>
        <column name="bigint_column" type="INT64"/>
        <column name="smallint_column" type="INT16"/>
        <column name="tinyint_column" type="INT8"/>
        <column name="float_column" type="FLOAT"/>
        <column name="double_column" type="DOUBLE"/>
        <column name="decimal_column" type="DECIMAL(22, 9)"/>
        <column name="uint8_column" type="UINT8"/>
        <column name="uint16_column" type="UINT16"/>
        <column name="unit32_column" type="UINT32"/>
        <column name="unit64_column" type="UINT64"/>
        <column name="text_column" type="TEXT"/>
        <column name="binary_column" type="BYTES"/>
        <column name="json_column" type="JSON"/>
        <column name="jsondocument_column" type="JSONDOCUMENT"/>
        <column name="date_column" type="DATE"/>
        <column name="datetime_column" type="DATETIME"/>
        <column name="timestamp_column" type="TIMESTAMP"/>
        <column name="interval_column" type="INTERVAL"/>
    </createTable>
</changeSet>
<changeSet author="kurdyukov-kir (generated)" id="1711556283305-2">
    <createTable tableName="episodes">
        <column name="series_id" type="INT64">
            <constraints nullable="false" primaryKey="true"/>
        </column>
        <column name="season_id" type="INT64">
            <constraints nullable="false" primaryKey="true"/>
        </column>
        <column name="episode_id" type="INT64">
            <constraints nullable="false" primaryKey="true"/>
        </column>
        <column name="title" type="TEXT"/>
        <column name="air_date" type="DATE"/>
    </createTable>
</changeSet>
<changeSet author="kurdyukov-kir (generated)" id="1711556283305-3">
    <createIndex indexName="title_index" tableName="episodes">
        <column name="title"/>
    </createIndex>
</changeSet>
```

Then you need to synchronize the generated changelog.xml the file, this is done by the command:

```
liquibase changelog-sync --changelog-file=changelog.xml
```

The result will be liquibase synchronization in your project:

Connecting to YDB

In the examples above, a Docker container was used, which didn't require any additional authentication settings.

List of different authentication options through URL parameters:

- Local or remote Docker (anonymous authentication):
  `jdbc:ydb:grpc://localhost:2136/local`
- Self-hosted cluster:
  `jdbc:ydb:grpcs://<host>:2135/Root/testdb?secureConnectionCertificate=file:~/myca.cer`
- Connect with token to the cloud instance:
  `jdbc:ydb:grpcs://<host>:2135/path/to/database?token=file:~/my_token`
- Connect with service account to the cloud instance:
  `jdbc:ydb:grpcs://<host>:2135/path/to/database?saFile=file:~/sa_key.json`

Also, if your cluster is configured using username and password, authentication is done through Liquibase parameters.

For more info about different authentication settings, refer to the section.

Query engines

Engine	Guide
Apache Spark™	Guide

Apache Spark™

Apache Spark™ is an open-source, distributed processing system used for big data workloads. It utilizes in-memory caching and optimized query execution for fast analytic queries against data of any size. It provides development APIs in Java, Scala, Python, and R, and supports code reuse across multiple workloads—batch processing, interactive queries, real-time analytics, machine learning, and graph processing. Apache Spark™ can work with YDB using the YDB Spark Connector, a special module that implements core Apache Spark™ primitives. It supports:

- Distribution of operations across YDB table partitions
- Scalable YDB table readings and writing
- Automatic creation of tables if they do not exist

> **Note**
>
> The connector may require additional memory on the Apache Spark™ executor side to work with better speed and performance. 4 GB or more memory per executor is highly recommended.

How to Use

To work with YDB in Apache Spark™, you need to add the YDB Spark Connector to your Apache Spark™ driver. This can be done in several ways:

- Download the connector dependency directly from Maven Central using the `--packages` option. It's recommended to use the latest published version:

  Spark Shell

  ```
  ~ $ spark-shell --master <master-url> --packages tech.ydb.spark:ydb-spark-connector-shaded:2.0.1 --conf
  spark.executor.memory=4g
  ```

  PySpark

  ```
  ~ $ pyspark --master <master-url> --packages tech.ydb.spark:ydb-spark-connector-shaded:2.0.1 --conf spar
  k.executor.memory=4g
  ```

  Spark SQL

  ```
  ~ $ spark-sql --master <master-url> --packages tech.ydb.spark:ydb-spark-connector-shaded:2.0.1 --conf sp
  ark.executor.memory=4g
  ```

- Download the latest version of the shaded connector (a connector build that includes all dependencies) from GitHub or Maven Central and specify the downloaded artifact in the `--jars` option:

  Spark Shell

  ```
  ~ $ spark-shell --master <master-url> --jars ~/Download/ydb-spark-connector-shaded-2.0.1.jar --conf spar
  k.executor.memory=4g
  ```

  PySpark

  ```
  ~ $ pyspark --master <master-url> --jars ~/Download/ydb-spark-connector-shaded-2.0.1.jar  --conf spark.e
  xecutor.memory=4g
  ```

  Spark SQL

  ```
  ~ $ spark-sql --master <master-url> --jars ~/Download/ydb-spark-connector-shaded-2.0.1.jar  --conf spar
  k.executor.memory=4g
  ```

- You can also copy the downloaded shaded artifact to the `jars` folder of your Apache Spark™ distribution. In this case, no additional options need to be specified.

Use DataFrame API

The DataFrame API allows you to work with YDB in an interactive `spark-shell` or `pyspark` session, as well as when writing code in `Java`, `Scala`, or `Python` for `spark-submit`.

To create a `DataFrame`, you need to specify the `ydb` format, pass a set of connection options and the path to the YDB table:

Scala

```
val ydb_df = spark.read.format("ydb").options(<options>).load("<table-path>")
```

Python

```
ydb_df = spark.read.format("ydb").options(<options>).load("<table-path>")
```

To save any `DataFrame` in the table YDB, you similarly need to specify the `ydb` format, connection options and the path to the table:

Scala

```
any_dataframe.write.format("ydb").options(<options>).mode("append").save("<table-path>")
```

Python

```
any_dataframe.write.format("ydb").options(<options>).mode("append").save("<table-path>")
```

> **Note**
>
> For writing data to YDB it is recommended to use the `append` mode, which uses batch data loading. If the table specified in the `save()` method does not exist, it will be created automatically according to the table autocreation options.

A more detailed example is provided in the Spark-shell example.

Use Catalog API

Catalogs allow you to work with YDB in interactive `spark-sql` sessions or execute SQL queries via the `spark.sql` method.
To access YDB, you need to add a catalog by specifying the following Apache Spark™ properties. You can define multiple catalogs with different names to access to different YDB databases:

```
# Mandatory catalog's driver name
spark.sql.catalog.<catalog_name>=tech.ydb.spark.connector.YdbCatalog
# Mandatory option, the url of database
spark.sql.catalog.<catalog_name>.url=<ydb-connection-url>
# Other options are not mandatory and may be specified as necessary
spark.sql.catalog.<catalog_name>.<param-name>=<param-value>
```

After that, you can work with YDB tables through standard Apache Spark™ SQL queries.
Note that you should use a dot `.` as a separator in the table path.

```
SELECT * FROM <catalog_name>.<table-path> LIMIT 10;
```

A more detailed example is provided in the Spark SQL example.

YDB Spark Connector Options

The behavior of the YDB Spark Connector is configured using options that can be passed as one set with the `options` method or specified individually with the `option` method. Each `DataFrame` and each individual operation on a `DataFrame` can have its own configuration of options.

Connection Options

- `url` — a required parameter with the YDB connection string in the following format:
  `grpc[s]://<endpoint>:<port>/<database>[?<options>]`
  Examples:
  - Local Docker container with anonymous authentication and without TLS:
    `grpc://localhost:2136/local`
  - Remote self-hosted cluster:
    `grpcs://my-private-cluster:2135/Root/my-database?secureConnectionCertificate=~/myCertificate.cer`
  - Cloud database instance with a token:
    `grpcs://ydb.my-cloud.com:2135/my_folder/test_database?tokenFile=~/my_token`
  - Cloud database instance with a service account key:
    `grpcs://ydb.my-cloud.com:2135/my_folder/test_database?saKeyFile=~/sa_key.json`
- `ca.text` — specifies the certificate value for establishing a TLS connection.
- `ca.file` — specifies the path to the certificate for establishing a TLS connection. You can specify it directly in `url` as the `secureConnectionCertificate` option.
- `auth.use_env` — if set to `true`, authentication based on environment variables will be used.
- `auth.use_metadata` — if set to `true`, metadata-based authentication mode will be used. You can specify it directly in `url` as the `useMetadata` option.
- `auth.login` and `auth.password` — login and password for static authentication.
- `auth.token` — authentication using the specified Access Token.
- `auth.token.file` — authentication using Access Token from the specified file. You can specify it directly in `url` as the `tokenFile` option.
- `auth.sakey.text` — used to specify the key content for authentication with a service account key.
- `auth.sakey.file` — used to specify the path to the key file for authentication with a service account key. You can specify it directly in `url` as the `saKeyFile` option.

Table Autocreation Options

> **Tip**
>
> If you need the table to have some custom settings configured, create it manually beforehand with CREATE TABLE or modify it afterward with ALTER TABLE.

- `table.autocreate` — if set to `true`, then when writing to a non-existent table, it will be created automatically. Enabled by default;

- `table.type` — the type of automatically created table. Possible values:
  - `row` for creating a row-oriented table (default).
  - `column` for creating a column-oriented table.
- `table.primary_keys` — a comma-separated list of columns to use as the primary key. If this option is not provided, a new column with random content will be used for the key.
- `table.auto_pk_name` — the name of the column for the randomly created key. This column will be created with the type `Utf8` and will be filled with random UUID v4 values. Default value is `_spark_key`.

Spark Shell and PySpark Example

As an example, we'll show how to load a list of all Stack Overflow posts from 2020 into YDB. This data can be downloaded from the following link: https://datasets-documentation.s3.eu-west-3.amazonaws.com/stackoverflow/parquet/posts/2020.parquet

Spark Shell

```
~ $ spark-shell --master <master-url> --packages tech.ydb.spark:ydb-spark-connector-shaded:2.0.1 --conf spar
k.executor.memory=4g
Spark session available as 'spark'.
Welcome to
      ____              __
     / __/__  ___ _____/ /__
    _\ \/ _ \/ _ `/ __/  '_/
  /___/ .__/\_,_/_/ /_/\_\   version 3.5.4
     /_/

Using Scala version 2.12.18 (OpenJDK 64-Bit Server VM, Java 17.0.15)
Type in expressions to have them evaluated.
Type :help for more information.
```

PySpark

```
~ $ pyspark --master <master-url> --packages tech.ydb.spark:ydb-spark-connector-shaded:2.0.1 --conf spark.exe
cutor.memory=4g
Welcome to
      ____              __
     / __/__  ___ _____/ /__
    _\ \/ _ \/ _ `/ __/  '_/
  /__ / .__/\_,_/_/ /_/\_\   version 3.5.4
     /_/

Using Python version 3.10.12 (main, May 27 2025 17:12:29)
SparkSession available as 'spark'.
```

Let's display the schema of the Parquet file and count the number of rows it contains:

Spark Shell

```
scala> val so_posts2020 = spark.read.format("parquet").load("/home/username/2020.parquet")
so_posts2020: org.apache.spark.sql.DataFrame = [Id: bigint, PostTypeId: bigint ... 20 more fields]

scala> so_posts2020.printSchema
root
|-- Id: long (nullable = true)
|-- PostTypeId: long (nullable = true)
|-- AcceptedAnswerId: long (nullable = true)
|-- CreationDate: timestamp (nullable = true)
|-- Score: long (nullable = true)
|-- ViewCount: long (nullable = true)
|-- Body: binary (nullable = true)
|-- OwnerUserId: long (nullable = true)
|-- OwnerDisplayName: binary (nullable = true)
|-- LastEditorUserId: long (nullable = true)
|-- LastEditorDisplayName: binary (nullable = true)
|-- LastEditDate: timestamp (nullable = true)
|-- LastActivityDate: timestamp (nullable = true)
|-- Title: binary (nullable = true)
|-- Tags: binary (nullable = true)
|-- AnswerCount: long (nullable = true)
|-- CommentCount: long (nullable = true)
|-- FavoriteCount: long (nullable = true)
|-- ContentLicense: binary (nullable = true)
|-- ParentId: binary (nullable = true)
|-- CommunityOwnedDate: timestamp (nullable = true)
|-- ClosedDate: timestamp (nullable = true)

scala> so_posts2020.count
res1: Long = 4304021
```

PySpark

```
>>> so_posts2020 = spark.read.format("parquet").load("/home/username/2020.parquet")
>>> so_posts2020.printSchema()
root
|-- Id: long (nullable = true)
|-- PostTypeId: long (nullable = true)
|-- AcceptedAnswerId: long (nullable = true)
|-- CreationDate: timestamp (nullable = true)
|-- Score: long (nullable = true)
|-- ViewCount: long (nullable = true)
|-- Body: binary (nullable = true)
|-- OwnerUserId: long (nullable = true)
|-- OwnerDisplayName: binary (nullable = true)
|-- LastEditorUserId: long (nullable = true)
|-- LastEditorDisplayName: binary (nullable = true)
|-- LastEditDate: timestamp (nullable = true)
|-- LastActivityDate: timestamp (nullable = true)
|-- Title: binary (nullable = true)
|-- Tags: binary (nullable = true)
|-- AnswerCount: long (nullable = true)
|-- CommentCount: long (nullable = true)
|-- FavoriteCount: long (nullable = true)
|-- ContentLicense: binary (nullable = true)
|-- ParentId: binary (nullable = true)
|-- CommunityOwnedDate: timestamp (nullable = true)
|-- ClosedDate: timestamp (nullable = true)

>>> so_posts2020.count()
4304021
```

Then add a new column with the year to this DataFrame and store it all to a column-oriented YDB table:

Spark Shell

```
scala> val my_ydb = Map("url" -> "grpcs://ydb.my-host.net:2135/preprod/spark-test?tokenFile=~/.token")
my_ydb: scala.collection.immutable.Map[String,String] = Map(url -> grpcs://ydb.my-host.net:2135/preprod/spark
-test?tokenFile=~/.token)

scala> so_posts2020.withColumn("Year", lit(2020)).write.format("ydb").options(my_ydb).option("table.type", "c
olumn").option("table.primary_keys", "Id").mode("append").save("stackoverflow/posts");
```

PySpark

```
>>> from pyspark.sql.functions import col,lit
>>> my_ydb = {"url": "grpcs://ydb.my-host.net:2135/preprod/spark-test?tokenFile=~/.token"}
>>> so_posts2020.withColumn("Year", lit(2020)).write.format("ydb").options(**my_ydb).option("table.type", "co
lumn").option("table.primary_keys", "Id").mode("append").save("stackoverflow/posts")
```

As a result, you can read the stored data from the YDB table and, for example, count the number of posts that have an accepted answer:

Spark Shell

```
scala> val ydb_posts2020 = spark.read.format("ydb").options(my_ydb).load("stackoverflow/posts")
ydb_posts2020: org.apache.spark.sql.DataFrame = [Id: bigint, PostTypeId: bigint ... 21 more fields]

scala> ydb_posts2020.printSchema
root
|-- Id: long (nullable = false)
|-- PostTypeId: long (nullable = true)
|-- AcceptedAnswerId: long (nullable = true)
|-- CreationDate: timestamp (nullable = true)
|-- Score: long (nullable = true)
|-- ViewCount: long (nullable = true)
|-- Body: binary (nullable = true)
|-- OwnerUserId: long (nullable = true)
|-- OwnerDisplayName: binary (nullable = true)
|-- LastEditorUserId: long (nullable = true)
|-- LastEditorDisplayName: binary (nullable = true)
|-- LastEditDate: timestamp (nullable = true)
|-- LastActivityDate: timestamp (nullable = true)
|-- Title: binary (nullable = true)
|-- Tags: binary (nullable = true)
|-- AnswerCount: long (nullable = true)
|-- CommentCount: long (nullable = true)
|-- FavoriteCount: long (nullable = true)
|-- ContentLicense: binary (nullable = true)
|-- ParentId: binary (nullable = true)
|-- CommunityOwnedDate: timestamp (nullable = true)
|-- ClosedDate: timestamp (nullable = true)
|-- Year: integer (nullable = true)

scala> ydb_posts2020.count
res3: Long = 4304021

scala> ydb_posts2020.filter(col("AcceptedAnswerId") > 0).count
res4: Long = 843780
```

PySpark

```
>>> ydb_posts2020 = spark.read.format("ydb").options(**my_ydb).load("stackoverflow/posts")
>>> ydb_posts2020.printSchema()
root
|-- Id: long (nullable = true)
|-- PostTypeId: long (nullable = true)
|-- AcceptedAnswerId: long (nullable = true)
|-- CreationDate: timestamp (nullable = true)
|-- Score: long (nullable = true)
|-- ViewCount: long (nullable = true)
|-- Body: binary (nullable = true)
|-- OwnerUserId: long (nullable = true)
|-- OwnerDisplayName: binary (nullable = true)
|-- LastEditorUserId: long (nullable = true)
|-- LastEditorDisplayName: binary (nullable = true)
|-- LastEditDate: timestamp (nullable = true)
|-- LastActivityDate: timestamp (nullable = true)
|-- Title: binary (nullable = true)
|-- Tags: binary (nullable = true)
|-- AnswerCount: long (nullable = true)
|-- CommentCount: long (nullable = true)
|-- FavoriteCount: long (nullable = true)
|-- ContentLicense: binary (nullable = true)
|-- ParentId: binary (nullable = true)
|-- CommunityOwnedDate: timestamp (nullable = true)
|-- ClosedDate: timestamp (nullable = true)
|-- Year: integer (nullable = true)

>>> ydb_posts2020.count()
4304021
>>> ydb_posts2020.filter(col("AcceptedAnswerId") > 0).count()
843780
```

Spark SQL example

As an example, we'll show how to load a list of all Stack Overflow posts from 2020 into YDB. This data can be downloaded from the following link: https://datasets-documentation.s3.eu-west-3.amazonaws.com/stackoverflow/parquet/posts/2020.parquet

First, let's run `spark-sql` with the configured `my_ydb` catalog:

```
~ $ spark-sql --master <master-url> --packages tech.ydb.spark:ydb-spark-connector-shaded:2.0.1 \
     --conf spark.sql.catalog.my_ydb=tech.ydb.spark.connector.YdbCatalog \
     --conf spark.sql.catalog.my_ydb.url=grpcs://ydb.my-host.net:2135/preprod/spark-test \
     --conf spark.sql.catalog.my_ydb.auth.token.file=~/.token \
     --conf spark.executor.memory=4g
spark-sql (default)>
```

Let's validate the current state of the connected database and confirm the absence of the `stackoverflow/posts` table:

```
spark-sql (default)> SHOW NAMESPACES FROM my_ydb;
stackoverflow
Time taken: 0.11 seconds, Fetched 1 row(s)
spark-sql (default)> SHOW TABLES FROM my_ydb.stackoverflow;
Time taken: 0.041 seconds
```

Let's count the number of rows in the original parquet file:

```
spark-sql (default)> SELECT COUNT(*) FROM parquet.`/home/username/2020.parquet`;
4304021
```

Let's add a new column with the year and copy it all to a new YDB table:

```
spark-sql (default)> CREATE TABLE my_ydb.stackoverflow.posts OPTIONS(table.primary_keys='Id') AS SELECT *, 20
20 as Year FROM parquet.`/home/username/2020.parquet`;
Time taken: 85.225 seconds
```

Let's verify that the new table has appeared in the YDB database:

```
spark-sql (default)> SHOW TABLES FROM my_ydb.stackoverflow;
posts
Time taken: 0.07 seconds, Fetched 1 row(s)
spark-sql (default)> DESCRIBE TABLE my_ydb.stackoverflow.posts;
Id                    bigint
PostTypeId            bigint
AcceptedAnswerId      bigint
CreationDate          timestamp
Score                 bigint
ViewCount             bigint
Body                  binary
OwnerUserId           bigint
OwnerDisplayName      binary
LastEditorUserId      bigint
LastEditorDisplayName binary
LastEditDate          timestamp
LastActivityDate      timestamp
Title                 binary
Tags                  binary
AnswerCount           bigint
CommentCount          bigint
FavoriteCount         bigint
ContentLicense        binary
ParentId              binary
CommunityOwnedDate    timestamp
ClosedDate            timestamp
Year                  int
```

As a result, we can read the stored data from YDB table and, for example, count the number of posts that have an accepted answer:

```
spark-sql (default)> SELECT COUNT(*) FROM my_ydb.stackoverflow.posts;
4304021
Time taken: 19.726 seconds, Fetched 1 row(s)
spark-sql (default)> SELECT COUNT(*) FROM my_ydb.stackoverflow.posts WHERE AcceptedAnswerId > 0;
843780
Time taken: 6.599 seconds, Fetched 1 row(s)
```

YDB dialect for Hibernate

Overview

This is a guide to using Hibernate with YDB.

Hibernate is an Object-Relational Mapping (ORM) framework for Java that facilitates the mapping of object-oriented models to SQL.

Installation

Add the following dependency to your project:

Maven

```
<!-- Set actual versions -->
<dependency>
    <groupId>tech.ydb.jdbc</groupId>
    <artifactId>ydb-jdbc-driver</artifactId>
    <version>${ydb.jdbc.version}</version>
</dependency>

<dependency>
    <groupId>tech.ydb.dialects</groupId>
    <artifactId>hibernate-ydb-dialect</artifactId>
    <version>${hibernate.ydb.dialect.version}</version>
</dependency>
```

Gradle

```
dependencies {
    // Set actual versions
    implementation "tech.ydb.dialects:hibernate-ydb-dialect:$ydbDialectVersion"
    implementation "tech.ydb.jdbc:ydb-jdbc-driver:$ydbJdbcVersion"
}
```

If you use Hibernate version 5, you need `<artifactId>hibernate-ydb-dialect-v5</artifactId>` for Maven or `implementation 'tech.ydb.dialects:hibernate-ydb-dialect-v5:$version` for Gradle instead of the similar package without the `-v5` suffix.

Configuration

Configure Hibernate to use the custom YDB dialect by updating your persistence.xml file:

```
<property name="hibernate.dialect">tech.ydb.hibernate.dialect.YdbDialect</property>
```

Or, if you are using programmatic configuration:

Java

```
import org.hibernate.cfg.AvailableSettings;
import org.hibernate.cfg.Configuration;

public static Configuration basedConfiguration() {
    return new Configuration()
            .setProperty(AvailableSettings.JAKARTA_JDBC_DRIVER, YdbDriver.class.getName())
            .setProperty(AvailableSettings.DIALECT, YdbDialect.class.getName());
}
```

Kotlin

```
import org.hibernate.cfg.AvailableSettings
import org.hibernate.cfg.Configuration

fun basedConfiguration(): Configuration = Configuration().apply {
    setProperty(AvailableSettings.JAKARTA_JDBC_DRIVER, YdbDriver::class.name)
    setProperty(AvailableSettings.DIALECT, YdbDialect::class.name)
}
```

Usage

Use this custom dialect just like any other Hibernate dialect. Map your entity classes to database tables and use Hibernate's session factory to perform database operations.

Table of comparison of Java types descriptions with YDB types:

Java type	YDB type
`bool`, `Boolean`	`Bool`
`String`, enum with annotation `@Enumerated(EnumType.STRING)`	`Text` (synonym `Utf8`)
`java.time.LocalDate`	`Date`
`java.math.BigDecimal`, `java.math.BigInteger`	`Decimal(22,9)`
`double`, `Double`	`Double`

`float`, `Float`	`Float`
`int`, `java.lang.Integer`	`Int32`
`long`, `java.lang.Long`	`Int64`
`short`, `java.lang.Short`	`Int16`
`byte`, `java.lang.Byte`, enum with annotation `@Enumerated(EnumType.ORDINAL)`	`Int8`
`[]byte`	`Bytes` (synonym `String`)
`java.time.LocalDateTime` (timezone will be set to `UTC`)	`Datetime`
`java.time.Instant` (timezone will be set to `UTC`)	`Timestamp`

YDB dialect supports database schema generation based on Hibernate entities.

For example, for the `Group` class:

Java

```java
@Getter
@Setter
@Entity
@Table(name = "Groups", indexes = @Index(name = "group_name_index", columnList = "GroupName"))
public class Group {

    @Id
    @Column(name = "GroupId")
    private int id;

    @Column(name = "GroupName")
    private String name;

    @OneToMany(mappedBy = "group")
    private List<Student> students;
}
```

Kotlin

```kotlin
@Entity
@Table(name = "Groups", indexes = [Index(name = "group_name_index", columnList = "GroupName")])
data class Group(
    @Id
    @Column(name = "GroupId")
    val id: Int,

    @Column(name = "GroupName")
    val name: String,

    @OneToMany(mappedBy = "group")
    val students: List<Student>
)
```

The following `Groups` table will be created, and the `GroupName` will be indexed by a global secondary index named `group_name_index`:

```
CREATE TABLE Groups (
    GroupId Int32 NOT NULL,
    GroupName Text,
    PRIMARY KEY (GroupId)
);

ALTER TABLE Groups
  ADD INDEX group_name_index GLOBAL
    ON (GroupName);
```

If you evolve the Group entity by adding the `deparment` field:

Java

```java
@Column
private String department;
```

Kotlin

```kotlin
@Column
val department: String
```

At the start of the application, Hibernate will update the database schema if the `update` mode is set in properties:

```
jakarta.persistence.schema-generation.database.action=update
```

The result of changing the schema is:

```
ALTER TABLE Groups
   ADD COLUMN department Text
```

> **Warning**
>
> Hibernate is not designed to manage database schemas. You can manage your database schema using Liquibase or Flyway.

YDB dialect supports `@OneToMany`, `@ManyToOne` and `@ManyToMany` relationships.

For example, for `@OneToMany` generates a SQL script:

FetchType.LAZY

```
SELECT
    g1_0.GroupId,
    g1_0.GroupName
FROM
    Groups g1_0
WHERE
    g1_0.GroupName='M3439'

SELECT
    s1_0.GroupId,
    s1_0.StudentId,
    s1_0.StudentName
FROM
    Students s1_0
WHERE
    s1_0.GroupId=?
```

FetchType.EAGER

```
SELECT
    g1_0.GroupId,
    g1_0.GroupName,
    s1_0.GroupId,
    s1_0.StudentId,
    s1_0.StudentName
FROM
    Groups g1_0
JOIN
    Students s1_0
        on g1_0.GroupId=s1_0.GroupId
WHERE
    g1_0.GroupName='M3439'
```

Example with Spring Data JPA

Configure Spring Data JPA with Hibernate to use custom YDB dialect by updating your `application.properties`:

```
spring.jpa.properties.hibernate.dialect=tech.ydb.hibernate.dialect.YdbDialect

spring.datasource.driver-class-name=tech.ydb.jdbc.YdbDriver
spring.datasource.url=jdbc:ydb:<grpc/grpcs>://<host>:<2135/2136>/path/to/database[?saFile=file:~/sa_key.json]
```

Create a simple entity and repository:

Java

```java
@Data
@Entity
@Table(name = "employee")
public class Employee {
    @Id
    private long id;

    @Column(name = "full_name")
    private String fullName;

    @Column
    private String email;

    @Column(name = "hire_date")
    private LocalDate hireDate;

    @Column
    private java.math.BigDecimal salary;

    @Column(name = "is_active")
    private boolean isActive;

    @Column
    private String department;

    @Column
    private int age;
}

public interface EmployeeRepository implements CrudRepository<Employee, Long> {}
```

Kotlin

```kotlin
@Entity
@Table(name = "employee")
data class Employee(
    @Id
    val id: Long,

    @Column(name = "full_name")
    val fullName: String,

    @Column
    val email: String,

    @Column(name = "hire_date")
    val hireDate: LocalDate,

    @Column
    val salary: java.math.BigDecimal,

    @Column(name = "is_active")
    val isActive: Boolean,

    @Column
    val department: String,

    @Column
    val age: Int,
)

interface EmployeeRepository : CrudRepository<Employee, Long>

fun EmployeeRepository.findByIdOrNull(id: Long): Employee? = this.findById(id).orElse(null)
```

Usage example:

Java

```
Employee employee = new Employee(
    1,
    "Example",
    "example@bk.com",
    LocalDate.parse("2023-12-20"),
    BigDecimal("500000.000000000"),
    true,
    "YDB AppTeam",
    23
);

/* The following SQL will be executed:
INSERT INTO employee (age,department,email,full_name,hire_date,is_active,limit_date_password,salary,id)
VALUES (?,?,?,?,?,?,?,?,?)
*/
employeeRepository.save(employee);

assertEquals(employee, employeeRepository.findById(employee.getId()).get());

/* The following SQL will be executed:
DELETE FROM employee WHERE id=?
 */
employeeRepository.delete(employee);

assertNull(employeeRepository.findById(employee.getId()).orElse(null));
```

Kotlin

```
val employee = Employee(
    1,
    "Example",
    "example@bk.com",
    LocalDate.parse("2023-12-20"),
    BigDecimal("500000.000000000"),
    true,
    "YDB AppTeam",
    23
)

/* The following SQL will be executed:
INSERT INTO employee (age,department,email,full_name,hire_date,is_active,limit_date_password,salary,id)
VALUES (?,?,?,?,?,?,?,?,?)
*/
employeeRepository.save(employee)

assertEquals(employee, employeeRepository.findByIdOrNull(employee.id))

/* The following SQL will be executed:
DELETE FROM employee WHERE id=?
 */
employeeRepository.delete(employee)

assertNull(employeeRepository.findByIdOrNull(employee.id))
```

An example of a simple Spring Data JPA repository can be found at the following link.

YDB Dialect for Spring Data JDBC

This guide is intended for use with Spring Data JDBC and YDB.

Spring Data JDBC is part of the Spring Data ecosystem, providing a simplified way to interact with relational databases using SQL and Java objects. Unlike Spring JPA, which relies on JPA (Java Persistence API), Spring Data offers a direct approach to working with databases, bypassing complex ORM (Object-Relational Mapping) for simpler methods.

Installing the YDB dialect

To integrate YDB with a Spring Data JDBC project, it needs two dependencies: the YDB JDBC driver and the Spring Data JDBC extension for YDB.

Examples for different build systems:

Maven

```
<!-- Set actual versions -->
<dependency>
    <groupId>tech.ydb.jdbc</groupId>
    <artifactId>ydb-jdbc-driver</artifactId>
    <version>${ydb.jdbc.version}</version>
</dependency>

<dependency>
    <groupId>tech.ydb.dialects</groupId>
    <artifactId>spring-data-jdbc-ydb</artifactId>
    <version>${spring.data.jdbc.ydb}</version>
</dependency>
```

Gradle

```
dependencies {
    // Set actual versions
    implementation "tech.ydb.dialects:spring-data-jdbc-ydb:$ydbDialectVersion"
    implementation "tech.ydb.jdbc:ydb-jdbc-driver:$ydbJdbcVersion"
}
```

Usage

After importing all the necessary dependencies, the dialect is ready for use. Below is a simple example of a Spring Data JDBC application.

```
spring.datasource.driver-class-name=tech.ydb.jdbc.YdbDriver
spring.datasource.url=jdbc:ydb:<grpc/grpcs>://<host>:<2135/2136>/path/to/database[?saFile=file:~/sa_key.json]
```

```
@Table(name = "Users")
public class User implements Persistable<Long> {
    @Id
    private Long id = ThreadLocalRandom.current().nextLong();

    private String login;
    private String firstname;
    private String lastname;

    @Transient
    private boolean isNew;

    // Constructors, getters and setters

    @Override
    public Long getId() {
      return id;
    }

    @Override
    public boolean isNew() {
      return isNew;
    }

    public void setNew(boolean isNew) {
      this.isNew = isNew;
    }
}
```

Creating a repository for the `User` entity in the `Users` table:

```
public interface SimpleUserRepository extends CrudRepository<User, Long> {
}
```

Saving a new user and verifying that it has been successfully saved:

```
@Component
public class UserRepositoryCommandLineRunner implements CommandLineRunner {

    @Autowired
    private SimpleUserRepository repository;

    @Override
    public void run(String... args) {
        User user = new User();
        user.setLogin("johndoe");
        user.setFirstname("John");
        user.setLastname("Doe");
        user.setNew(true);  // Setting the flag for the new entity

        // Save user
        User savedUser = repository.save(user);

        // Check saved user
        assertThat(repository.findById(savedUser.getId())).contains(savedUser);

        System.out.println("User saved with ID: " + savedUser.getId());
    }
}
```

View Index

To generate `VIEW INDEX` statements from repository methods, use the `@ViewIndex` annotation. The `@ViewIndex` annotation has two fields:

- `indexName`: The index name.
- `tableName`: The table name to which the `VIEW INDEX` is bound, which is particularly useful when using the `@MappedCollection` annotation.

Here is an example of an index on the Users table by the `login` field:

```
public interface SimpleUserRepository extends CrudRepository<User, Long> {

    @ViewIndex(indexName = "login_index")
    User findByLogin(String login);
}
```

The query generated by this method will look as follows:

```
SELECT
    `Users`.`id` AS `id`,
    `Users`.`login` AS `login`,
    `Users`.`lastname` AS `lastname`,
    `Users`.`firstname` AS `firstname`
FROM `Users` VIEW login_index AS `Users` WHERE `Users`.`login` = ?
```

YdbType

The `@YdbType` annotation allows you to declare a specific YDB data type for an entity field. Here is an example of its usage:

```
    @YdbType("Json")
    private String jsonColumn;
    @YdbType("JsonDocument")
    private String jsonDocumentColumn;
    @YdbType("Uint8")
    private byte uint8Column;
    @YdbType("Uint16")
    private short uint16Column;
    @YdbType("Uint32")
    private int uint32Column;
    @YdbType("Uint64")
    private long uint64Column;
```

Using the `@YdbType` annotation allows you to accurately specify the data types supported by YDB, ensuring proper interaction with the database.

A complete example of a simple Spring Data JDBC repository is available on GitHub.

JOOQ extension for YDB

This guide explains how to use JOOQ with YDB.

JOOQ is a Java library that allows you to create type-safe SQL queries by generating Java classes from a database schema and providing convenient query builders.

Generating Java Classes

You can generate Java classes using any of the tools provided on the official JOOQ website. Two dependencies are required: the YDB JDBC driver and the JOOQ extension for YDB, along with two parameters:

- `database.name` : `tech.ydb.jooq.codegen.YdbDatabase` (mandatory setting)
- `strategy.name` : `tech.ydb.jooq.codegen.YdbGeneratorStrategy` (recommended setting)

An example using the `maven` plugin:

```
<plugin>
    <groupId>org.jooq</groupId>
    <artifactId>jooq-codegen-maven</artifactId>
    <version>3.19.11</version>
    <executions>
        <execution>
            <goals>
                <goal>generate</goal>
            </goals>
        </execution>
    </executions>
    <dependencies>
        <dependency>
            <groupId>tech.ydb.jdbc</groupId>
            <artifactId>ydb-jdbc-driver</artifactId>
            <version>${ydb.jdbc.version}</version>
        </dependency>
        <dependency>
            <groupId>tech.ydb.dialects</groupId>
            <artifactId>jooq-ydb-dialect</artifactId>
            <version>${jooq.ydb.version}</version>
        </dependency>
    </dependencies>
    <configuration>
        <jdbc>
            <driver>tech.ydb.jdbc.YdbDriver</driver>
            <url>jdbc:ydb:grpc://localhost:2136/local</url>
        </jdbc>
        <generator>
            <strategy>
                <name>tech.ydb.jooq.codegen.YdbGeneratorStrategy</name>
            </strategy>
            <database>
                <name>tech.ydb.jooq.codegen.YdbDatabase</name>
                <!-- excluding system tables -->
                <excludes>.sys.*</excludes>
            </database>
            <target>
                <packageName>ydb</packageName>
                <directory>./src/main/java</directory>
            </target>
        </generator>
    </configuration>
</plugin>
```

Example of generated classes from YQL tutorial (full file contents are available on GitHub):

```
ydb/DefaultCatalog.java
ydb/default_schema
ydb/default_schema/tables
ydb/default_schema/tables/Seasons.java
ydb/default_schema/tables/records
ydb/default_schema/tables/records/SeriesRecord.java
ydb/default_schema/tables/records/EpisodesRecord.java
ydb/default_schema/tables/records/SeasonsRecord.java
ydb/default_schema/tables/Series.java
ydb/default_schema/tables/Episodes.java
ydb/default_schema/Indexes.java
ydb/default_schema/Keys.java
ydb/default_schema/Tables.java
ydb/default_schema/DefaultSchema.java
```

Usage

To integrate YDB with JOOQ into your project, you need to add two dependencies: YDB JDBC Driver and the JOOQ extension for YDB.

Examples for different build systems:

Maven

```
<!-- Set actual versions -->
<dependency>
    <groupId>tech.ydb.jdbc</groupId>
    <artifactId>ydb-jdbc-driver</artifactId>
    <version>${ydb.jdbc.version}</version>
</dependency>

<dependency>
    <groupId>tech.ydb.dialects</groupId>
    <artifactId>jooq-ydb-dialect</artifactId>
    <version>${jooq.ydb.dialect.version}</version>
</dependency>
```

Gradle

```
dependencies {
    // Set actual versions
    implementation "tech.ydb.dialects:jooq-ydb-dialect:$jooqYdbDialectVersion"
    implementation "tech.ydb.jdbc:ydb-jdbc-driver:$ydbJdbcVersion"
}
```

To obtain a `YdbDSLContext` class instance (an extension of `org.jooq.DSLContext`), use the `tech.ydb.jooq.YDB` class. For example:

```
String url = "jdbc:ydb:<schema>://<host>:<port>/path/to/database[?saFile=file:~/sa_key.json]";
Connection conn = DriverManager.getConnection(url);

YdbDSLContext dsl = YDB.using(conn);
```

or

```
String url = "jdbc:ydb:<schema>://<host>:<port>/path/to/database[?saFile=file:~/sa_key.json]";
try(CloseableYdbDSLContext dsl = YDB.using(url)) {
    // ...
}
```

`YdbDSLContext` is ready to use.

YQL statements

The following statements are available from the YQL syntax in `YdbDSLContext`:

- `UPSERT`:

```
// generated SQL:
// upsert into `episodes` (`series_id`, `season_id`, `episode_id`, `title`, `air_date`)
// values (?, ?, ?, ?, ?)
public void upsert(YdbDSLContext context) {
    context.upsertInto(EPISODES)
            .set(record)
            .execute();
}
```

- `REPLACE`:

```
// generated SQL:
// replace into `episodes` (`series_id`, `season_id`, `episode_id`, `title`, `air_date`)
// values (?, ?, ?, ?, ?)
public void replace(YdbDSLContext context) {
    ydbDSLContext.replaceInto(EPISODES)
            .set(record)
            .execute();
}
```

- `VIEW index_name`:

```
// generated SQL:
// select `series`.`series_id`, `series`.`title`, `series`.`series_info`, `series`.`release_date`
// from `series` view `title_name` where `series`.`title` = ?
var record = ydbDSLContext.selectFrom(SERIES.useIndex(Indexes.TITLE_NAME.name))
        .where(SERIES.TITLE.eq(title))
        .fetchOne();
```

In all other respects, the YDB dialect follows the JOOQ documentation.

Spring Boot Configuration

Extend `JooqAutoConfiguration.DslContextConfiguration` with your own `YdbDSLContext`. For example:

```
@Configuration
public class YdbJooqConfiguration extends JooqAutoConfiguration.DslContextConfiguration {

    @Override
    public YdbDSLContextImpl dslContext(org.jooq.Configuration configuration) {
        return YdbDSLContextImpl(configuration);
    }
}
```

```
spring.datasource.driver-class-name=tech.ydb.jdbc.YdbDriver
spring.datasource.url=jdbc:ydb:<schema>://<host>:<port>/path/to/database[?saFile=file:~/sa_key.json]
```

A complete example of a simple Spring Boot application can be found on GitHub.

Using Dapper

Dapper is a micro ORM (Object-Relational Mapping) tool that provides a simple and flexible way to interact with databases. It operates on top of the ADO.NET standard and offers various features that simplify database operations.

Getting started

To get started, you need an additional dependency Dapper.

Let's consider a complete example:

```
using Dapper;
using Ydb.Sdk.Ado;

await using var connection = await new YdbDataSource().OpenConnectionAsync();

await connection.ExecuteAsync("""
                              CREATE TABLE Users(
                                  Id Int32,
                                  Name Text,
                                  Email Text,
                                  PRIMARY KEY (Id)
                              );
                              """);

await connection.ExecuteAsync("INSERT INTO Users(Id, Name, Email) VALUES (@Id, @Name, @Email)",
    new User { Id = 1, Name = "Name", Email = "Email" });

Console.WriteLine(await connection.QuerySingleAsync<User>("SELECT * FROM Users WHERE Id = @Id", new { Id = 1
}));

await connection.ExecuteAsync("DROP TABLE Users");

internal class User
{
    public int Id { get; init; }
    public string Name { get; init; } = null!;
    public string Email { get; init; } = null!;

    public override string ToString()
    {
        return $"Id: {Id}, Name: {Name}, Email: {Email}";
    }
}
```

For more information, refer to the official documentation.

Important aspects

For Dapper to interpret `DateTime` values as the YDB type `DateTime`, execute the following code:

```
SqlMapper.AddTypeMap(typeof(DateTime), DbType.DateTime);
```

By default, `DateTime` is interpreted as `Timestamp`.

YDB Entity Framework Core Provider

YDB has an Entity Framework (EF) Core provider, an object-relational mapper (ORM) that enables .NET developers to work with a YDB database using .NET objects. It behaves like other EF Core providers (for example, SQL Server). If you're just getting started with EF Core, the EF Core documentation is the best place to start.

EF Core Provider is being developed in the open GitHub repository, all problems should be reported there.

Set Up the YDB Entity Framework Core Provider

To get started, you need to add the necessary NuGet packages to your project:

```
dotnet add package EntityFrameworkCore.Ydb
```

Defining a Model and a DbContext

Let's say you want to store blogs and their posts in a database. You can model these as .NET types as follows:

```
public class Blog
{
    public int BlogId { get; set; }
    public string Url { get; set; }

    public List<Post> Posts { get; set; }
}

public class Post
{
    public int PostId { get; set; }
    public string Title { get; set; }
    public string Content { get; set; }

    public int BlogId { get; set; }
    public Blog Blog { get; set; }
}
```

You then define a `DbContext` type, which you'll use to interact with the database:

OnConfiguring

Using `OnConfiguring()` to configure your context is the easiest way to get started but is discouraged for most production applications:

```
public class BloggingContext : DbContext
  {
  public DbSet<Blog> Blogs { get; set; }
  public DbSet<Post> Posts { get; set; }

      protected override void OnConfiguring(DbContextOptionsBuilder optionsBuilder)
          => optionsBuilder.UseYdb("<connection string>");
  }

  // At the point where you need to perform a database operation:
  using var context = new BloggingContext();
  // Use the context...
```

DbContext pooling

```
var dbContextFactory = new PooledDbContextFactory<BloggingContext>(
  new DbContextOptionsBuilder<BloggingContext>()
      .UseYdb("<connection string>")
      .Options);

// At the point where you need to perform a database operation:
using var context = dbContextFactory.CreateDbContext();
// Use the context...
```

ASP.NET / DI

```
var builder = WebApplication.CreateBuilder(args);

builder.Services.AddDbContextPool<BloggingContext>(opt =>
    opt.UseYdb(builder.Configuration.GetConnectionString("BloggingContext")));

public class BloggingContext(DbContextOptions<BloggingContext> options) : DbContext(options)
{
    public DbSet<Blog> Blogs { get; set; }
    public DbSet<Post> Posts { get; set; }
}
```

For more information on getting started with EF, see the Getting Started guide.

Additional YDB Configuration

The Entity Framework (EF) Core provider for YDB has its own additional configuration parameters.

Connection with Yandex Cloud

You can find more information about different authentication methods for Yandex Cloud in the ADO.NET documentation.

Below is an example of how to specify the necessary parameters for connecting to Yandex Cloud using Entity Framework:

```
.UseYdb(cmd.ConnectionString, builder => builder
    .WithCredentialsProvider(saProvider)
    .WithServerCertificates(YcCerts.GetYcServerCertificates())
)
```

Schema Migration

To ensure that database schema migrations are executed correctly, disable the automatic retry strategy (`ExecutionStrategy`), which is enabled by default in `EntityFrameworkCore.Ydb`.

To do this, explicitly override the `IDesignTimeDbContextFactory` interface and use the `DisableRetryOnFailure()` method.

An example implementation of a context factory for migrations is shown below:

```
internal class BloggingContextFactory : IDesignTimeDbContextFactory<BloggingContext>
{
    public BloggingContext CreateDbContext(string[] args)
    {
        var optionsBuilder = new DbContextOptionsBuilder<BloggingContext>();

        return new BloggingContext(
            optionsBuilder.UseYdb("Host=localhost;Port=2136;Database=/local",
                builder => builder.DisableRetryOnFailure()
            ).Options
        );
    }
}
```

Note

This factory class is required to execute migration commands. For example:

```
dotnet ef migrations add MyMigration
dotnet ef database update
```

Examples

You can find complete usage examples on GitHub.

YDB Provider for LinqToDB

Overview

This guide explains how to use LinqToDB with YDB.

linq2db is a lightweight and fast ORM for .NET that provides type-safe LINQ queries and precise SQL control. The YDB provider generates correct YQL, supports YDB types, schema generation, and bulk operations (Bulk Copy).

Installing the YDB provider

Add dependencies:

dotnet CLI

```
dotnet add package Community.Ydb.Linq2db
dotnet add package linq2db
```

csproj (PackageReference)

```
<ItemGroup>
    <PackageReference Include="Community.Ydb.Linq2db" Version="$(CommunityYdbLinqToDbVersion)" />
    <PackageReference Include="linq2db" Version="$(LinqToDbVersion)" />
</ItemGroup>
```

Provider Configuration

Configure LinqToDB to use YDB in code:

C#

```
DataConnection.AddProviderDetector(YdbTools.ProviderDetector);

// Option 1: local YDB via connection string
//
// Example: local YDB running on localhost:2136 with database "/local"
using var localDb = new DataConnection(
    new DataOptions().UseConnectionString(
        "YDB",
        "Host=localhost;Port=2136;Database=/local;UseTls=false"
    )
);

// Option 2: managed YDB in cloud only via YdbConnectionStringBuilder
//
// Example: connection built from explicit host/port/database settings.
static async Task<DataConnection> BuildYdbDataConnection()
{
    var ydbConnectionBuilder = new YdbConnectionStringBuilder
    {
        Host     = "server",
        Port     = 2135,
        Database = "/ru-prestable/my-table",
        UseTls   = true
    };

    await using var ydbConnection = new YdbConnection(ydbConnectionBuilder);
    return YdbTools.CreateDataConnection(ydbConnection);
}
```

Usage

Use the provider like any other Linq To DB provider: map your entity classes to tables and run queries via `DataConnection` / `ITable<T>`. Below you'll find the type mapping table and schema generation examples.

Type Mapping between .NET and YDB

.NET type(s)	Linq To DB `DataType`	YDB type	Notes
`bool`	`Boolean`	`Bool`	—
`string`	`NVarChar` / `VarChar` / `Char` / `NChar`	`Text`	UTF-8 text. Text and Utf8 are the same in YDB; the DDL generator may output either
`byte[]`	`VarBinary` / `Binary` / `Blob`	`Bytes`	Binary data. Bytes and String are equivalent in YDB; DDL may show either
`Guid`	`Guid`	`Uuid`	128-bit RFC 4122 UUID. No version enforcement (v1/v4/v7). Generate the desired version in the app
`DateOnly` / `DateTime`	`Date`	`Date`	Date-only value stored as YDB `Date` in UTC, range `1970-01-01` .. `2106-01-01`. .NET `DateOnly` / `DateTime` support a wider range (`0001` .. `9999`), but values outside the YDB range cannot be stored.

`DateTime`	`DateTime`	`Datetime`	YDB `Datetime` with second precision, UTC instant in the range `1970-01-01` .. `2106-01-01`. .NET `DateTime` supports a wider range; values outside the YDB range are not supported. `DateTime.Kind` is not stored; the provider expects UTC values.
`DateTime` / `DateTimeOffset`	`DateTime2`	`Timestamp`	YDB `Timestamp` with microsecond precision, UTC instant `1970-01-01` .. `2106-01-01`. When writing `DateTimeOffset`, the value is converted to UTC; the offset/time zone is not persisted.
`TimeSpan`	`Interval`	`Interval`	Duration with microsecond precision. .NET `TimeSpan` range is wider than YDB `Interval`; values outside the YDB range are not supported. Sub-microsecond ticks are truncated.
`decimal`	`Decimal`	`Decimal(p,s)`	Default: Decimal(22,9). To use custom precision/scale, specify Decimal(p,s). Example
`float`	`Single`	`Float`	—
`double`	`Double`	`Double`	—
`sbyte` / `byte`	`SByte` / `Byte`	`Int8` / `Uint8`	—
`short` / `ushort`	`Int16` / `UInt16`	`Int16` / `Uint16`	—
`int` / `uint`	`Int32` / `UInt32`	`Int32` / `Uint32`	—
`long` / `ulong`	`Int64` / `UInt64`	`Int64` / `Uint64`	—
`string`	`Json`	`Json`	Text JSON.
`byte[]`	`BinaryJson`	`JsonDocument`	Binary JSON.
`DateOnly` / `DateTime`	`Date`	`Date32`	Wider date range. Use `DbType = "Date32"`. Example
`DateTime`	`DateTime`	`Datetime64`	Second precision, wider range. `DbType = "Datetime64"`. Example
`DateTime` / `DateTimeOffset`	`DateTime2`	`Timestamp64`	Microseconds, wider range. `DbType = "Timestamp64"`. Example
`TimeSpan`	`Interval`	`Interval64`	Wider interval range. `DbType = "Interval64"`. Example

Tip

You can set exact `Precision` / `Scale` with attributes: `[Column(DataType = DataType.Decimal, Precision = 22, Scale = 9)]`.

Note

By default (when `DbType` is not specified), the provider uses legacy YDB temporal types: `Date`, `Datetime`, `Timestamp`, `Interval`. To opt in per column to extended types, set `DbType`, e.g. `[Column(DbType = "Date32")]`. Both families can coexist in the same table.

Custom precision scale example

C#

```
[Table("amounts")]
public sealed class AmountRow
{
    [PrimaryKey] public long Id { get; set; }

    // Custom precision & scale: Decimal(25,10)
    [Column("amount", DataType = DataType.Decimal, Precision = 25, Scale = 10), NotNull]
    public decimal Amount { get; set; }
}
```

DbType override example

C#

```
[Table("events")]
public sealed class EventRow
{
[PrimaryKey] public long Id { get; set; }

    // Extended-range timestamp
    [Column("happened_at", DbType = "Timestamp64"), NotNull]
    public DateTime HappenedAt { get; set; }

    // Extended-range date
    [Column("due_on", DbType = "Date32"), NotNull]
    public DateTime DueOn { get; set; }

    // Second precision date
    [Column("made_at", DbType = "Datetime64"), NotNull]
    public DateTime MadeAt { get; set; }

    // Extended-range interval
    [Column("duration", DbType = "Interval64"), NotNull]
    public TimeSpan Duration { get; set; }
}
```

Schema Generation from Attributes

Describe an entity using Linq To DB attributes, then explicitly create the schema by calling db.CreateTable(). At that moment the table is created, and any [Index] attributes are applied as database indexes.

C#

```
using LinqToDB.Mapping;

[Table(Name = "Groups")]
[Index("GroupName", Name = "group_name_index")]
public class Group
{
    [PrimaryKey, Column("GroupId")]
    public int Id { get; set; }

    [Column("GroupName")]
    public string? Name { get; set; }
}
```

Generated DDL (YDB):

```
CREATE TABLE Groups (
    GroupId Int32 NOT NULL,
    GroupName Utf8,
    PRIMARY KEY (GroupId)
);

ALTER TABLE Groups
  ADD INDEX group_name_index GLOBAL
       ON (GroupName);
```

Schema evolution (adding a column)

Add the `Department` column to the `Group` entity:

C#

```
[Column] public string? Department { get; set; }
```

Schema change (DDL):

```
ALTER TABLE Groups
   ADD COLUMN Department Utf8;
```

> **Note**
>
> Linq To DB doesn't manage migrations. The DDL below is illustrative—apply it with Liquibase/Flyway (recommended). For quick local changes you can also run it directly with db.Execute(...) or the YDB CLI.

C#

```
using var db = new DataConnection("YDB", connectionString);

// Apply the schema change (adds the column):
db.Execute(@"ALTER TABLE Groups
   ADD COLUMN Department Utf8;");
```

YDB Indexes how to set parameters

With the [Index] attribute you can set name and columns. The provider creates a GLOBAL secondary index.
Parameters like ASYNC/SYNC and COVER(...) are not supported via the attribute; add them using a separate DDL statement after table creation.

Option A — attribute (name + columns)

C#

```
[Table(Name = "Groups", IsColumnAttributeRequired = false)]
[Index("GroupName", Name = "group_name_index")]
public class Group
{
    [PrimaryKey, Column("GroupId")] public int Id { get; set; }
    [Column("GroupName")] public string? Name { get; set; }

    // A column you may include into COVER via separate DDL
    [Column] public string? Department { get; set; }
}

// When you call db.CreateTable<Group>(), a GLOBAL index on GroupName is created.
```

The generated DDL is effectively

```
CREATE TABLE Groups (
    GroupId Int32 NOT NULL,
    GroupName Utf8,
    Department Utf8,
    PRIMARY KEY (GroupId)
);

ALTER TABLE Groups
  ADD INDEX group_name_index GLOBAL
       ON (GroupName);
```

Option B — extended parameters (ASYNC, COVER) via separate DDL

C#

```
[Table(Name = "Groups", IsColumnAttributeRequired = false)]
public class Group
{
    [PrimaryKey, Column("GroupId")] public int Id { get; set; }
    [Column("GroupName")] public string? Name { get; set; }
    [Column] public string? Department { get; set; }
}

public static class Demo
{
    public static void Main()
    {
        using var db = new DataConnection("YDB", connectionString);

        // 1) Create table from attributes (avoid duplicate indexes if you plan to add them via DDL)
        db.CreateTable<Group>();

        // 2) Add an index with ASYNC and COVER parameters
        db.Execute(@"
ALTER TABLE Groups
  ADD INDEX group_name_index GLOBAL ASYNC
       ON (GroupName)
       COVER (Department);
");
    }
}
```

Relationships between entities

Describe navigations using `[Association]` attributes. Example of one-to-many between `Group` and `Student`:

C#

```
[Table("Students")]
public class Student
{
    [PrimaryKey, Column("StudentId")]
    public int Id { get; set; }

    [Column("StudentName")]
    public string Name { get; set; } = null!;

    [Column]
    public int GroupId { get; set; }

    // many-to-one
    [Association(ThisKey = nameof(GroupId), OtherKey = nameof(Group.Id), CanBeNull = false)]
    public Group Group { get; set; } = null!;
}

[Table("Groups")]
public class Group
{
    [PrimaryKey, Column("GroupId")]
    public int Id { get; set; }

    [Column("GroupName")]
    public string? Name { get; set; }

    // one-to-many
    [Association(ThisKey = nameof(Id), OtherKey = nameof(Student.GroupId))]
    public IEnumerable<Student> Students { get; set; } = null!;
}
```

Created tables:

```
CREATE TABLE Groups (
    GroupId Int32 NOT NULL,
    GroupName Utf8,
    PRIMARY KEY (GroupId)
);

CREATE TABLE Students (
    StudentId Int32 NOT NULL,
    StudentName Utf8,
    GroupId Int32,
    PRIMARY KEY (StudentId)
);
```

Example generated YQL for relationship queries

C#: “Lazy” loading (two queries)

```
  // 1) SELECT g.GroupId, g.GroupName FROM Groups AS g WHERE g.GroupName = 'M3439';
  var grp = db.GetTable<Group>()
  .Where(g => g.Name == "M3439")
  .Select(g => new { g.Id, g.Name })
  .FirstOrDefault();

  // 2) SELECT s.StudentId, s.StudentName, s.GroupId FROM Students AS s WHERE s.GroupId = ?;
  var students = grp == null
  ? new List<Student>()
  : db.GetTable<Student>()
  .Where(s => s.GroupId == grp.Id)
  .Select(s => new { s.Id, s.Name, s.GroupId })
  .ToList();
```

C#: “Eager” loading (JOIN)

```
  var joined =
  (from g in db.GetTable<Group>()
  join s in db.GetTable<Student>() on g.Id equals s.GroupId
  where g.Name == "M3439"
  select new { GroupId = g.Id, GroupName = g.Name, StudentId = s.Id, StudentName = s.Name, s.GroupId })
  .ToList();
```

YQL: “Lazy” loading (two queries)

```
SELECT
    g.GroupId,
    g.GroupName
FROM
    Groups AS g
WHERE
    g.GroupName = 'M3439';

SELECT
    s.StudentId,
    s.StudentName,
    s.GroupId
FROM
    Students AS s
WHERE
    s.GroupId = ?;
```

YQL: “Eager” loading (JOIN)

```
SELECT
    g.GroupId,
    g.GroupName,
    s.StudentId,
    s.StudentName,
    s.GroupId
FROM
    Groups AS g
JOIN
    Students AS s
  ON g.GroupId = s.GroupId
WHERE
    g.GroupName = 'M3439';
```

Bulk operations: insert, update and delete

BulkCopy:

In the YDB provider, `BulkCopy` uses the native `BulkUpsert API` and does not generate textual YQL. Rows are sent to YDB as a stream of strongly-typed values over the SDK's binary protocol, so there are no DECLARE statements or ? placeholders

C#

```
var now  = DateTime.UtcNow;
var data = Enumerable.Range(0, 15_000).Select(i => new SimpleEntity
{
    Id      = i,
    IntVal  = i,
    DecVal  = 0m,
    StrVal  = $"Name {i}",
    BoolVal = (i & 1) == 0,
    DtVal   = now,
});

  db.BulkCopy(data)
```

Massive Update (WHERE IN):

C#

```
var ids = Enumerable.Range(0, 15_000).ToArray();

table.Where(t => ids.Contains(t.Id))
    .Set(_ => _.DecVal, 1.23m)
    .Set(_ => _.StrVal, "updated")
    .Set(_ => _.BoolVal, true)
    .Update();
```

YQL

```
DECLARE $Gen_List_Primitive_1 AS List<Int32>;
UPDATE
    SimpleEntity
SET
    DecVal = Decimal('1.23', 22, 9),
    StrVal = 'updated'u,
    BoolVal = true
WHERE
    SimpleEntity.Id IN $Gen_List_Primitive_1
```

Mass deletion (WHERE IN):

C#

```
table.Delete(t => ids.Contains(t.Id));
```

YQL

```
DECLARE $Gen_List_Primitive_1 AS List<Int32>;
DELETE FROM
    SimpleEntity
WHERE
    SimpleEntity.Id IN $Gen_List_Primitive_1
```

A complete example

This section shows a practical, production-style entity from a typical domain. It demonstrates:

- a realistic column set (name, email, hire date, salary, flags, ints);
- precise types (e.g., Decimal(22,9) for money-like values, Date for dates, Utf8/Bool/Int32/Int64);
- a GLOBAL secondary index on full_name for lookups and ordering;
- end-to-end flow: mapping → table creation → CRUD with generated YQL/DDL.

When you call `db.CreateTable<Employee>()`, Linq To DB creates the table and applies the [Index] attribute as a YDB GLOBAL index.

C#

```
using System;
using LinqToDB.Mapping;

[Table("employee")]
[Index("full_name", Name = "employee_full_name_idx")]
public class Employee
{
    [PrimaryKey] public long Id { get; set; }

    [Column("full_name"), NotNull] public string FullName { get; set; } = null!;

    [Column, NotNull] public string Email { get; set; } = null!;

    [Column("hire_date", DataType = DataType.Date), NotNull]
    public DateTime HireDate { get; set; }

    [Column(DataType = DataType.Decimal, Precision = 22, Scale = 9), NotNull]
    public decimal Salary { get; set; }

    [Column("is_active"), NotNull] public bool IsActive { get; set; }

    [Column, NotNull] public string Department { get; set; } = null!;

    [Column, NotNull] public int Age { get; set; }
}
```

Generated DDL:

```
CREATE TABLE employee (
    Id Int64 NOT NULL,
    full_name Utf8 NOT NULL,
    Email Utf8 NOT NULL,
    hire_date Date NOT NULL,
    Salary Decimal(22,9) NOT NULL,
    is_active Bool NOT NULL,
    Department Utf8 NOT NULL,
    Age Int32 NOT NULL,
    PRIMARY KEY (Id)
);

ALTER TABLE employee
  ADD INDEX employee_full_name_idx GLOBAL
       ON (full_name);
```

Usage example

C#

```
using System;
using System.Linq;
using LinqToDB;
using LinqToDB.Data;

// This example uses a direct connection string and is intended for local / test YDB instances.
// If you need to connect to managed YDB in Yandex Cloud , use YdbConnectionStringBuilder
// and YdbConnection instead (see the provider configuration section)

using var db = new DataConnection(
  new DataOptions().UseConnectionString(
    "YDB",
    "Host=localhost;Port=2136;Database=/local;UseTls=false"
  )
);

// INSERT
var employee = new Employee
{
    Id         = 1L,
    FullName   = "Example",
    Email      = "example@example.com",
    HireDate   = new DateTime(2023, 12, 20),
    Salary     = 500000.000000000m,
    IsActive   = true,
    Department = "YDB AppTeam",
    Age        = 23,
};
db.Insert(employee);

// SELECT by primary key
var loaded = db.GetTable<Employee>()
               .FirstOrDefault(e => e.Id == employee.Id);

// UPDATE Email/Department/Salary by primary key
db.GetTable<Employee>()
  .Where(e => e.Id == employee.Id)
  .Set(e => e.Email,      "example+updated@example.com")
  .Set(e => e.Department, "Analytics")
  .Set(e => e.Salary,     550000.000000000m)
  .Update();

// DELETE by primary key
db.GetTable<Employee>()
  .Where(e => e.Id == employee.Id)
  .Delete();
```

YQL samples generated by the provider for simple operations:

- Insert a single row

```
INSERT INTO employee (Age,Department,Email,full_name,hire_date,is_active,Salary,Id)
VALUES (?,?,?,?,?,?,?,?);
```

- Read by primary key

```
SELECT
    e.Id, e.full_name, e.Email, e.hire_date, e.Salary, e.is_active, e.Department, e.Age
FROM employee AS e
WHERE e.Id = ?;
```

- Update by primary key

```
UPDATE employee
SET
    Email      = ?,
    Department = ?,
    Salary     = ?
WHERE Id = ?;
```

> **Note**
>
> The provider emits parameters (?) because values and types are bound via the driver, not declared in the query text. When YQL requires typed parameters, the provider adds the necessary DECLARE statements automatically. For non-standard patterns such as upsert-style writes, use YDB's UPSERT with parameter binding—the provider generates these statements as regular YQL with parameters.

- Delete by primary key

```
DELETE FROM employee WHERE Id = ?;
```

SQLAlchemy

SQLAlchemy is a popular Python library for working with databases, providing both ORM (Object-Relational Mapping) and Core API for executing SQL queries.

YDB supports integration with SQLAlchemy through a special `ydb-sqlalchemy` dialect, which provides full compatibility with SQLAlchemy 2.0 and partial support for SQLAlchemy 1.4.

Installation

Install the `ydb-sqlalchemy` package using pip:

```
pip install ydb-sqlalchemy
```

Quick Start

Synchronous Connection

```
import sqlalchemy as sa

# Create engine
engine = sa.create_engine("yql+ydb://localhost:2136/local")

# Execute query
with engine.connect() as conn:
    result = conn.execute(sa.text("SELECT 1 AS value"))
    print(result.fetchone())
```

Asynchronous Connection

```
import asyncio
import sqlalchemy as sa
from sqlalchemy.ext.asyncio import create_async_engine

async def main():
    # Create async engine
    engine = create_async_engine("yql+ydb_async://localhost:2136/local")

    # Execute query
    async with engine.connect() as conn:
        result = await conn.execute(sa.text("SELECT 1 AS value"))
        print(await result.fetchone())

asyncio.run(main())
```

Connection Configuration

Authentication Methods

Anonymous Access

For local development or testing:

```
import sqlalchemy as sa

engine = sa.create_engine("yql+ydb://localhost:2136/local")
```

Static Credentials

Use username and password authentication:

```
engine = sa.create_engine(
    "yql+ydb://localhost:2136/local",
    connect_args={
        "credentials": {
            "username": "your_username",
            "password": "your_password"
        }
    }
)
```

Token Authentication

Use access token for authentication:

```
engine = sa.create_engine(
    "yql+ydb://localhost:2136/local",
    connect_args={
        "credentials": {
            "token": "your_access_token"
        }
    }
)
```

Service Account Authentication

Use service account JSON key:

```
import json

# Load from file
with open('service_account_key.json', 'r') as f:
    service_account_json = json.load(f)

engine = sa.create_engine(
    "yql+ydb://localhost:2136/local",
    connect_args={
        "credentials": {
            "service_account_json": service_account_json
        }
    }
)

# Or pass JSON directly
engine = sa.create_engine(
    "yql+ydb://localhost:2136/local",
    connect_args={
        "credentials": {
            "service_account_json": {
                "id": "your_key_id",
                "service_account_id": "your_service_account_id",
                "created_at": "2023-01-01T00:00:00Z",
                "key_algorithm": "RSA_2048",
                "public_key": "-----BEGIN PUBLIC KEY-----\n...\n-----END PUBLIC KEY-----",
                "private_key": "-----BEGIN PRIVATE KEY-----\n...\n-----END PRIVATE KEY-----"
            }
        }
    }
)
```

Using YDB SDK Credentials

You can use any available authentication methods from YDB Python SDK:

```
import ydb.iam

# Metadata service
engine = sa.create_engine(
    "yql+ydb://localhost:2136/local",
    connect_args={
        "credentials": ydb.iam.MetadataUrlCredentials()
    }
)

# OAuth token
engine = sa.create_engine(
    "yql+ydb://localhost:2136/local",
    connect_args={
        "credentials": ydb.iam.OAuthCredentials("your_oauth_token")
    }
)

# Static credentials
engine = sa.create_engine(
    "yql+ydb://localhost:2136/local",
    connect_args={
        "credentials": ydb.iam.StaticCredentials("username", "password")
    }
)
```

TLS Configuration

For secure connections to YDB:

```
engine = sa.create_engine(
    "yql+ydb://ydb.example.com:2135/prod",
    connect_args={
        "credentials": {"token": "your_token"},
        "protocol": "grpc",
        "root_certificates_path": "/path/to/ca-certificates.crt",
        # "root_certificates": crt_string,  # Alternative - certificate string
    }
)
```

Supported Data Types

YDB SQLAlchemy provides comprehensive support for YDB data types through custom SQLAlchemy types. For detailed information about YDB data types, see the YDB Data Types Documentation.

Type Mapping Summary

YDB Type	YDB SQLAlchemy Type	Standard SQLAlchemy Type	Python Type	Notes
`Bool`	`Boolean`	`Boolean`	`bool`	
`Int8`	`Int8`		`int`	-2^7 to 2^7-1
`Int16`	`Int16`		`int`	-2^15 to 2^15-1
`Int32`	`Int32`		`int`	-2^31 to 2^31-1
`Int64`	`Int64`	`Integer`	`int`	-2^63 to 2^63-1
`Uint8`	`UInt8`		`int`	0 to 2^8-1
`Uint16`	`UInt16`		`int`	0 to 2^16-1
`Uint32`	`UInt32`		`int`	0 to 2^32-1
`Uint64`	`UInt64`		`int`	0 to 2^64-1
`Float`	`Float`	`Float`	`float`	
`Double`	`Double`		`float`	Available in SQLAlchemy 2.0+
`Decimal(p,s)`	`Decimal`	`DECIMAL`	`decimal.Decimal`	
`String`		`BINARY`	`bytes`	
`Utf8`		`String/Text`	`str`	
`Date`	`YqlDate`	`Date`	`datetime.date`	
`Date32`	`YqlDate32`		`datetime.date`	Extended date range support
`Datetime`	`YqlDateTime`	`DATETIME`	`datetime.datetime`	
`Datetime64`	`YqlDateTime64`		`datetime.datetime`	Extended range
`Timestamp`	`YqlTimestamp`	`TIMESTAMP`	`datetime.datetime`	
`Timestamp64`	`YqlTimestamp64`		`datetime.datetime`	Extended range
`Json`	`YqlJSON`	`JSON`	`dict/list`	
`List<T>`	`ListType`	`ARRAY`	`list`	
`Struct<...>`	`StructType`		`dict`	
`Optional<T>`	`nullable=True`		`None + base type`	

Migrations with Alembic

YDB-Specific Configuration

YDB requires special configuration in `env.py` due to its unique characteristics:

```python
# migrations/env.py
from logging.config import fileConfig
import sqlalchemy as sa
from sqlalchemy import engine_from_config, pool
from alembic import context
from alembic.ddl.impl import DefaultImpl

# Import your models
from myapp.models import Base

config = context.config

if config.config_file_name is not None:
    fileConfig(config.config_file_name)

target_metadata = Base.metadata

# YDB-specific implementation
class YDBImpl(DefaultImpl):
    __dialect__ = "yql"

def run_migrations_offline() -> None:
    """Run migrations in 'offline' mode."""
    url = config.get_main_option("sqlalchemy.url")
    context.configure(
        url=url,
        target_metadata=target_metadata,
        literal_binds=True,
        dialect_opts={"paramstyle": "named"},
    )

    with context.begin_transaction():
        context.run_migrations()

def run_migrations_online() -> None:
    """Run migrations in 'online' mode."""
    connectable = engine_from_config(
        config.get_section(config.config_ini_section, {}),
        prefix="sqlalchemy.",
        poolclass=pool.NullPool,
    )

    with connectable.connect() as connection:
        context.configure(
            connection=connection,
            target_metadata=target_metadata
        )

        with context.begin_transaction():
            context.run_migrations()

if context.is_offline_mode():
    run_migrations_offline()
else:
    run_migrations_online()
```

Django

Django is a popular Python web framework with a powerful ORM for working with databases.

YDB supports integration with Django through a special `django-ydb-backend` backend, which provides full Django ORM support for working with YDB.

Quick Start

Installation

Install the `django-ydb-backend` package using pip:

```
pip install django-ydb-backend
```

Connection Setup

Add YDB to your Django settings in `settings.py`:

```
DATABASES = {
    "default": {
        "NAME": "ydb_db",
        "ENGINE": "ydb_backend.backend",
        "HOST": "localhost",
        "PORT": "2136",
        "DATABASE": "/local",
    }
}
```

Configuration

DATABASES

Required parameters:

- **NAME** (required): traditional Django database name
- **ENGINE** (required): must be set to `ydb_backend.backend`
- **HOST** (required): hostname or IP address of the YDB server (e.g., "localhost")
- **PORT** (required): gRPC port YDB is running on (default is 2136)
- **DATABASE** (required): full path to your YDB database (e.g., "/local" for local testing or "/my_production_db")

```
DATABASES = {
    "default": {
        "NAME": "ydb_db",
        "ENGINE": "ydb_backend.backend",
        "HOST": "localhost",
        "PORT": "2136",
        "DATABASE": "/local",
    }
}
```

Authentication Methods

Anonymous Authentication

To use anonymous authentication, you don't need to pass any additional parameters.

Static Authentication

To use static credentials, you should provide `username` and `password`:

```
DATABASES = {
    "default": {
        "ENGINE": "ydb_backend.backend",
        "CREDENTIALS": {
            "username": "...",
            "password": "..."
        }
    }
}
```

Token Authentication

To use access token credentials, you should provide `token`:

```
DATABASES = {
    "default": {
        "ENGINE": "ydb_backend.backend",
        "CREDENTIALS": {
            "token": "..."
        },
    }
}
```

Service Account Authentication

To use service account credentials, you should provide `service_account_json`:

```
DATABASES = {
    "default": {
        "ENGINE": "ydb_backend.backend",
        "CREDENTIALS": {
            "service_account_json": {
                "id": "...",
                "service_account_id": "...",
                "created_at": "...",
                "key_algorithm": "...",
                "public_key": "...",
                "private_key": "..."
            }
        }
    }
}
```

Django Fields

YDB backend supports Django builtin fields.

Note: ForeignKey, ManyToManyField or even OneToOneField could be used with YDB backend. However, it's important to note that these relationships won't enforce database-level constraints, which may lead to potential data consistency issues.

Supported Django Fields

Class	YDB Type	Python Type	Comments
`SmallAutoField`	`Int16`	`int`	YDB type SmallSerial will generate value automatically. Range -32768 to 32767
`AutoField`	`Int32`	`int`	YDB type Serial will generate value automatically. Range -2147483648 to 2147483647
`BigAutoField`	`Int64`	`int`	YDB type BigSerial will generate value automatically. Range -9223372036854775808 to 9223372036854775807
`CharField`	`UTF-8`	`str`	
`TextField`	`UTF-8`	`str`	
`BinaryField`	`String`	`bytes`	
`SlugField`	`UTF-8`	`str`	
`FileField`	`String`	`bytes`	
`FilePathField`	`UTF-8`	`str`	
`DateField`	`Date`	`datetime.date`	Range of values for all time types except Interval: From 00:00 01.01.1970 to 00:00 01.01.2106. Internal Date representation: Unsigned 16-bit integer
`DateTimeField`	`DateTime`	`datetime.datetime`	Internal representation: Unsigned 32-bit integer
`DurationField`	`Interval`	`int`	The range of values is from -136 years to +136 years. The internal representation is a 64–bit signed integer. Cannot be used in the primary key
`SmallIntegerField`	`Int16`	`int`	Range -32768 to 32767
`IntegerField`	`Int32`	`int`	Range -2147483648 to 2147483647
`BigIntegerField`	`Int64`	`int`	Range -9223372036854775808 to 9223372036854775807
`PositiveSmallIntegerField`	`UInt16`	`int`	Range 0 to 65535
`PositiveIntegerField`	`UInt32`	`int`	Range 0 to 4294967295
`PositiveBigIntegerField`	`UInt64`	`int`	Range 0 to 18446744073709551615
`FloatField`	`Float`	`float`	A real number with variable precision, 4 bytes in size. Can't be used in the primary key
`DecimalField`	`Decimal`	`Decimal`	Pythonic values are rounded to fit the scale of the database field. Supports only Decimal(22,9)
`UUIDField`	`UUID`	`uuid.UUID`	
`IPAddressField`	`UTF-8`	`str`	
`GenericIPAddressField`	`UTF-8`	`str`	
`BooleanField`	`Bool`	`boolean`	
`EmailField`	`UTF-8`	`str`

Dialect YDB for Kotlin Exposed

Introduction

This guide describes using JetBrains Exposed with YDB.

Exposed is a Kotlin library for working with a database via SQL DSL and DAO API on top of JDBC. The YDB dialect adds support for YDB-compatible SQL, YDB data type mapping, retry-aware transactions for optimistic concurrency control, and YDB-specific schema features.

The guide covers two practical scenarios:

- Main JDBC dialect for Exposed
- Example of custom configuration for Spring Boot 3 applications.

Installing the YDB dialect

Examples for various build systems:

Maven

```
<!-- Укажите актуальные версии -->
<dependency>
    <groupId>tech.ydb.jdbc</groupId>
    <artifactId>ydb-jdbc-driver</artifactId>
    <version>${ydb.jdbc.version}</version>
</dependency>

<dependency>
    <groupId>tech.ydb.dialects</groupId>
    <artifactId>kotlin-exposed-ydb-dialect</artifactId>
    <version>${exposed.ydb.dialect.version}</version>
</dependency>
```

Gradle

```
dependencies {
    // Specify the current versions
    implementation "tech.ydb.jdbc:ydb-jdbc-driver:$ydbJdbcVersion"
    implementation "tech.ydb.dialects:kotlin-exposed-ydb-dialect:$ydbDialectVersion"
}
```

Current versions of artifacts:

- `tech.ydb.dialects:kotlin-exposed-ydb-dialect` on Maven Central
- `tech.ydb.jdbc:ydb-jdbc-driver` — same as above.

If the application uses DAO, JSON DSL, or other Exposed modules, connect them in the standard way together with the main dialect.

Connection and configuration

First, register the dialect and driver, then open `Database` through a regular `Database.connect(...)` and pass the recommended values `DatabaseConfig`:

```
import org.jetbrains.exposed.v1.core.DatabaseConfig
import org.jetbrains.exposed.v1.jdbc.Database
import tech.ydb.exposed.dialect.registerYdbDialect
import java.sql.Connection

registerYdbDialect()

val db = Database.connect(
    url = "jdbc:ydb:grpc://localhost:2136/local",
    driver = "tech.ydb.jdbc.YdbDriver",
    databaseConfig = DatabaseConfig {
        useNestedTransactions = false
    }
)
```

`registerYdbDialect()`:

- Registers the JDBC driver `tech.ydb.jdbc.YdbDriver` for URLs with the prefix `jdbc:ydb:`.
- registers `YdbDialect` in Exposed
- registers a metadata bridge for reading existing secondary indexes via JDBC metadata.

Recommended Exposed configuration for YDB includes:

- `useNestedTransactions = false` — a setting on the Exposed side that prevents Exposed from emulating nested transactions. YDB does not support nested transactions, so such emulation would lead to errors.
- registration of `YdbDialect` through `registerYdbDialect(...)` before opening `Database`.

DDL features in YDB

Basic usage of Exposed — defining tables, DSL/DAO queries, transactions, etc. — is described in the official JetBrains Exposed documentation. This section only covers YDB-specific features of DDL dialect generation.

Creating tables

In YDB `CREATE TABLE` must contain a table `PRIMARY KEY (...)`. The standard Exposed 1.3.0 DDL path for tables with a single-column PK can generate an inline form:

```
id Int32 PRIMARY KEY
```

YDB does not accept this form. Therefore, for tables that should be created via Exposed DDL, you need to override `createStatement()` and call `createYdbStatement()`:

```
import org.jetbrains.exposed.v1.core.PrimaryKey
import org.jetbrains.exposed.v1.core.Table
import tech.ydb.exposed.dialect.createYdbStatement
import tech.ydb.exposed.dialect.javatime.ydbTimestamp64
import tech.ydb.exposed.dialect.ydbDecimal

object Products : Table("products") {
    val id = integer("id")
    val sku = varchar("sku", 64)
    val name = varchar("name", 255)
    val category = varchar("category", 128)
    val price = ydbDecimal("price", precision = 10, scale = 2)
    val expiresAt = ydbTimestamp64("expires_at")

    override val primaryKey = PrimaryKey(id)

    init {
        index(false, sku)
    }

    override fun createStatement(): List<String> = createYdbStatement()
}
```

`createYdbStatement()`:

- renders all columns without inline `PRIMARY KEY`
- Adds a table `PRIMARY KEY (...)`
- saves `NOT NULL` and `DEFAULT`
- preserves `storageParameters`, therefore YDB-specific `WITH (...)` can be described through the standard Exposed API.

Schema creation is performed using standard Exposed tools:

```
import org.jetbrains.exposed.v1.jdbc.SchemaUtils
import tech.ydb.exposed.dialect.ydbTransaction

ydbTransaction(db) {
    SchemaUtils.create(Products)
}
```

YDB-specific table parameters

TTL and other YDB-specific table options are set via `storageParameters`:

```
import org.jetbrains.exposed.v1.core.PrimaryKey
import org.jetbrains.exposed.v1.core.RawTableStorageParameter
import org.jetbrains.exposed.v1.core.Table
import org.jetbrains.exposed.v1.core.TableStorageParameter
import tech.ydb.exposed.dialect.createYdbStatement
import tech.ydb.exposed.dialect.javatime.ydbTimestamp64

object Sessions : Table("sessions") {
    val id = integer("id")
    val expireAt = ydbTimestamp64("expire_at")

    override val primaryKey = PrimaryKey(id)

    override val storageParameters: List<TableStorageParameter> =
        listOf(RawTableStorageParameter("TTL = Interval(\"PT1H\") ON expire_at"))

    override fun createStatement(): List<String> = createYdbStatement()
}
```

Secondary indexes declared via the standard `Table.index(...)` are created separately via:

```
ALTER TABLE ... ADD INDEX ... GLOBAL
```

Arbitrary YQL via `createYdbStatement()`

`createYdbStatement()` returns `List<String>`, so you can add arbitrary YQL statements to the generated DDL — for example, `CREATE TABLE` of a columnar table, `ALTER TABLE ADD INDEX ... LOCAL`, or any other DDL that the dialect does not cover first-class.

```
import org.jetbrains.exposed.v1.core.PrimaryKey
import org.jetbrains.exposed.v1.core.Table
import tech.ydb.exposed.dialect.createYdbStatement

object EventsColumn : Table("events_column") {
    val id = integer("id")
    val name = varchar("name", 255)

    override val primaryKey = PrimaryKey(id)

    override fun createStatement(): List<String> = createYdbStatement() + listOf(
        """
        CREATE TABLE events_column_olap (
            id Int32 NOT NULL,
            payload Json,
            PRIMARY KEY (id)
        ) WITH (STORE = COLUMN)
        """.trimIndent()
    )
}
```

This is a convenient way to describe tables for which the Exposed DSL does not cover the required YDB syntax. To manage the schema as a whole, it is recommended to use Flyway or Liquibase.

Read and write operations

Standard Exposed DSL operations (`select`, `insert`, `update`, `deleteWhere`) work without additional modifications.

The dialect also uses native operations YDB `UPSERT` and `REPLACE` through extensions `Table.upsert(...)`, `Table.batchUpsert(...)`, and `Table.replace(...)`:

```
import java.math.BigDecimal

Products.upsert {
    it[id] = 1
    it[sku] = "BOOK-001"
    it[name] = "Kotlin in Action"
    it[category] = "books"
    it[price] = BigDecimal("39.90")
}

Products.replace {
    it[id] = 1
    it[sku] = "BOOK-001"
    it[name] = "Kotlin in Action, 2nd edition"
    it[category] = "books"
    it[price] = BigDecimal("44.90")
}
```

The semantics correspond to the YQL statements `UPSERT INTO` and `REPLACE INTO`.
Exposed-specific parameters `onUpdate` and `keyColumns` for `upsert(...)` are ignored, and `upsert(where)` and PostgreSQL-like logic `ON CONFLICT DO UPDATE` are not supported.

> **Warning**
>
> The ANSI `MERGE` dialect is intentionally not supported. In YDB scenarios, its role is performed by `UPSERT` and `REPLACE`.

Repeatable transactions

YDB uses optimistic concurrency control, so a transaction may end with a retryable error and require re-execution. For this, the dialect provides `ydbTransaction(...)`:

```
import tech.ydb.exposed.dialect.YdbRetryConfig
import tech.ydb.exposed.dialect.ydbTransaction

ydbTransaction(db) {
    // regular read-write transaction
}

ydbTransaction(db, retry = YdbRetryConfig.IDEMPOTENT) {
    // safely repeatable operation
}

ydbTransaction(db, readOnly = true, retry = YdbRetryConfig.IDEMPOTENT) {
    // read-only scenario
}
```

`YdbRetryConfig.IDEMPOTENT` should only be used when the transaction body can be safely re-executed.

Data types

Table mapping standard Exposed types to YDB types:

Exposed	YDB

`byte` / `ubyte`	`Int8` / `Uint8`
`short` / `ushort`	`Int16` / `Uint16`
`integer` / `uinteger`	`Int32` / `Uint32`
`long`	`Int64`
`float` / `double`	`Float` / `Double`
`bool`	`Bool`
`varchar` / `text`	`Text`
`binary` / `blob`	`Bytes`
`uuid`	`Uuid`
`date`	`Date` or `Date32`
`datetime`	`Datetime` or `Datetime64`
`timestamp`	`Timestamp` or `Timestamp64`
`json`	`Json`
`jsonb`	`JsonDocument`

Features:

- `varchar(n)` maps to `Text`; the length constraint is not encoded in YDB DDL;
- `jsonb` corresponds to `JsonDocument` — this is a binary JSON representation optimized for efficient retrieval via `JSON_VALUE` / `JSON_EXISTS` / `JSON_QUERY`. `JsonDocument` itself cannot be used as a B-tree index key (in YDB, JSON is not a comparable type);
- `autoIncrement()` maps to `Serial` or `BigSerial`.

YDB-specific types

The dialect adds a set of extensions for columns:

```
import tech.ydb.exposed.dialect.ydbDecimal
import tech.ydb.exposed.dialect.ydbInterval
import tech.ydb.exposed.dialect.ydbInterval64
import tech.ydb.exposed.dialect.ydbJson
import tech.ydb.exposed.dialect.ydbJsonDocument
import tech.ydb.exposed.dialect.ydbUbyte
import tech.ydb.exposed.dialect.ydbUint32
import tech.ydb.exposed.dialect.ydbUint64
import tech.ydb.exposed.dialect.ydbUshort
import tech.ydb.exposed.dialect.ydbUlong
import tech.ydb.exposed.dialect.ydbUuid

val amount = ydbDecimal("amount", precision = 22, scale = 9)
val payload = ydbJson("payload")
val indexedPayload = ydbJsonDocument("indexed_payload")
val uid = ydbUuid("uid")
val flags = ydbUbyte("flags")
val counter = ydbUint32("counter")
val total = ydbUint64("total")
val someField = ydbUshort("some_field")
val totalFullRange = ydbUlong("total_full_range")
val duration = ydbInterval("duration")
val duration64 = ydbInterval64("duration64")
```

Mapping of YDB types and Kotlin runtime types:

Function	YDB type	Kotlin type
`ydbDecimal(name, p, s)`	`Decimal(p, s)`	`java.math.BigDecimal`
`ydbInterval(name)`	`Interval`	`java.time.Duration`
`ydbInterval64(name)`	`Interval64`	`java.time.Duration`
`ydbJson(name)`	`Json`	`String`
`ydbJsonDocument(name)`	`JsonDocument`	`String`
`ydbUuid(name)`	`Uuid`	`java.util.UUID`
`ydbUbyte(name)`	`Uint8`	`kotlin.UByte`
`ydbUshort(name)`	`Uint16`	`kotlin.UShort`
`ydbUint32(name)`	`Uint32`	`kotlin.UInt`
`ydbUint64(name)`	`Uint64`	`kotlin.Long` (`0..Long.MAX_VALUE`)
`ydbUlong(name)`	`Uint64`	`kotlin.ULong`

For literal values of `Decimal` in update expressions, `ydbDecimalLiteral(...)` is available.

Explicit selection of temporal type at the column level

```
import org.jetbrains.exposed.v1.core.PrimaryKey
import org.jetbrains.exposed.v1.core.Table
import tech.ydb.exposed.dialect.createYdbStatement
import tech.ydb.exposed.dialect.javatime.ydbDate
import tech.ydb.exposed.dialect.javatime.ydbDate32
import tech.ydb.exposed.dialect.javatime.ydbDatetime
import tech.ydb.exposed.dialect.javatime.ydbDatetime64
import tech.ydb.exposed.dialect.javatime.ydbTimestamp
import tech.ydb.exposed.dialect.javatime.ydbTimestamp64

object Events : Table("events") {
    val id = integer("id")
    val legacyDate = ydbDate("legacy_date")
    val signedDate = ydbDate32("signed_date")
    val legacyDatetime = ydbDatetime("legacy_datetime")
    val signedDatetime = ydbDatetime64("signed_datetime")
    val legacyTimestamp = ydbTimestamp("legacy_timestamp")
    val signedTimestamp = ydbTimestamp64("signed_timestamp")

    override val primaryKey = PrimaryKey(id)
    override fun createStatement(): List<String> = createYdbStatement()
}
```

Note

`registerYdbDialect(enableSignedDatetimes = true)` changes DDL names only for standard Exposed `date`, `datetime`, and `timestamp`. Explicit `ydbDate(...)`, `ydbDate32(...)`, `ydbDatetime(...)`, `ydbDatetime64(...)`, `ydbTimestamp(...)`, and `ydbTimestamp64(...)` always generate the type reflected in the function name.

Warning

`ydbUint64(...)` stores a value in Kotlin `Long`, so only the `0..Long.MAX_VALUE` range is supported. For values above `Long.MAX_VALUE`, use `ydbUlong(...)` — it is represented by the Kotlin type `ULong` and covers the entire YQL `Uint64` range.

Integration with Spring Boot 3

For Spring Boot 3, it is recommended to use the official Exposed scenario from the Spring Boot 3 integration documentation and add a small YDB-specific configuration to the application.

The logic of the previously existing starter module can serve as a reference for such manual configuration: in the application, you need to explicitly register the dialect, explicitly specify the YDB JDBC driver, match `forceSignedDatetimes=...` in the URL, and create `Database` from Spring-managed `DataSource`.

Dependencies

Maven

```
<!-- Укажите актуальную версию -->
<dependency>
    <groupId>org.jetbrains.exposed</groupId>
    <artifactId>exposed-spring-boot-starter</artifactId>
    <version>${exposed.version}</version>
</dependency>
<dependency>
    <groupId>tech.ydb.dialects</groupId>
    <artifactId>kotlin-exposed-ydb-dialect</artifactId>
    <version>${exposed.ydb.dialect.version}</version>
</dependency>
<dependency>
    <groupId>tech.ydb.jdbc</groupId>
    <artifactId>ydb-jdbc-driver</artifactId>
    <version>${ydb.jdbc.version}</version>
</dependency>
```

Gradle

```
dependencies {
    // Specify the current version
    implementation "org.jetbrains.exposed:exposed-spring-boot-starter:$exposedVersion"
    implementation "tech.ydb.dialects:kotlin-exposed-ydb-dialect:$ydbDialectVersion"
    implementation "tech.ydb.jdbc:ydb-jdbc-driver:$ydbJdbcVersion"
}
```

Basic Spring Boot configuration

```
spring:
  datasource:
    url: jdbc:ydb:grpc://localhost:2136/local?forceSignedDatetimes=false
    driver-class-name: tech.ydb.jdbc.YdbDriver
  exposed:
    generate-ddl: false
    show-sql: false
    ydb:
      enable-signed-datetimes: false
```

The standard properties of the official Exposed starter remain available, including:

- `spring.exposed.generate-ddl`
- `spring.exposed.excluded-packages`
- `spring.exposed.show-sql`

The example above uses a YDB-specific property:

- `spring.exposed.ydb.enable-signed-datetimes`

In this variant, the property name `spring.exposed.ydb.enable-signed-datetimes` is chosen by the application itself by convention with the rest of the configuration. It can be replaced with any other name if more convenient. If signed mode is enabled, the value in this property must be aligned with the JDBC URL, i.e., use `forceSignedDatetimes=true`.

Custom configuration example

Below is a minimal example of `@Configuration` that adds YDB-specific steps to the standard Spring Boot Exposed integration:

- Calls `registerYdbDialect(...)`.
- Sets the recommended values of `DatabaseConfig`.
- Creates a bean `Database` from Spring-managed `DataSource`.

```
import org.jetbrains.exposed.v1.core.DatabaseConfig
import org.jetbrains.exposed.v1.jdbc.Database
import org.springframework.beans.factory.InitializingBean
import org.springframework.beans.factory.annotation.Value
import org.springframework.context.annotation.Bean
import org.springframework.context.annotation.Configuration
import org.springframework.context.annotation.DependsOn
import tech.ydb.exposed.dialect.registerYdbDialect
import java.sql.Connection
import javax.sql.DataSource

@Configuration
class YdbExposedConfiguration(
    @Value("\${spring.exposed.ydb.enable-signed-datetimes:false}")
    private val enableSignedDatetimes: Boolean
) {
    @Bean
    fun ydbDialectRegistration(): InitializingBean = InitializingBean {
        registerYdbDialect(enableSignedDatetimes = enableSignedDatetimes)
    }

    @Bean
    fun databaseConfig(): DatabaseConfig = DatabaseConfig {
        defaultIsolationLevel = Connection.TRANSACTION_SERIALIZABLE
        defaultReadOnly = false
        useNestedTransactions = false
    }

    @Bean
    @DependsOn("ydbDialectRegistration")
    fun database(dataSource: DataSource, databaseConfig: DatabaseConfig): Database =
        Database.connect(
            datasource = dataSource,
            databaseConfig = databaseConfig
        )
}
```

If the application already has its own logic for creating `DataSource` or `Database`, the same steps can be moved into it. The key YDB-specific actions here remain the same: register the dialect, manually align `forceSignedDatetimes` in the JDBC URL, explicitly specify `tech.ydb.jdbc.YdbDriver`, and pass the recommended `DatabaseConfig` to Exposed.

Thus, in a typical case, it is sufficient to:

1. Add `exposed-spring-boot-starter`, `kotlin-exposed-ydb-dialect`, and `ydb-jdbc-driver`.
2. Specify `spring.datasource.url` starting with `jdbc:ydb:` and containing `forceSignedDatetimes=...`.
3. Add a custom `@Configuration` similar to the example above.
4. Enable `spring.exposed.ydb.enable-signed-datetimes=true` if necessary.

That is, the YDB integration for Spring Boot is described here as an explicit application configuration, not as a separate starter artifact.

Automatic schema generation

`spring.exposed.generate-ddl=true` works the same as in the official Exposed starter: on application startup, Exposed creates a schema based on the discovered `Table` classes.

For YDB, there is an important nuance here: tables that should be created via DDL must be declared using a regular `Table` with an override:

```
override fun createStatement(): List<String> = createYdbStatement()
```

> **Warning**
>
> If you enable `spring.exposed.generate-ddl=true` and leave tables on plain `Table` or `IdTable` without this override, Exposed will generate an inline `PRIMARY KEY` that YDB does not accept.

Transactions in Spring

For standard Spring integration, use `@Transactional`:

```
import org.springframework.stereotype.Service
import org.springframework.transaction.annotation.Transactional

@Service
class ProductService {
    @Transactional
    fun renameProduct(id: Int, newName: String) {
        // Exposed DSL
    }
}
```

`@Transactional` provides the usual Spring Exposed integration, but does not add a YDB retry policy for optimistic concurrency conflicts.

If a retry-aware path with automatic retries on YDB retryable errors is required, in your Spring service you can call `ydbTransaction(...)` directly, passing the bean `Database`:

```
import org.springframework.stereotype.Service
import org.jetbrains.exposed.v1.jdbc.Database
import tech.ydb.exposed.dialect.YdbRetryConfig
import tech.ydb.exposed.dialect.ydbTransaction

@Service
class RetryableProductService(
    private val database: Database
) {
    fun saveOrUpdate() =
        ydbTransaction(database, retry = YdbRetryConfig.IDEMPOTENT) {
            // Exposed DSL
        }
}
```

Typically, for one piece of code, one of two paths is chosen:

- Either `@Transactional`.
- Or `ydbTransaction(database, ...)` if automatic retries are needed.

Schema management

For production scenarios, it is recommended to consider Exposed DDL generation as a supplementary, not primary, path. Typically, the schema:

1. Is described by separate SQL scripts.
2. Is migrated by an external versioning tool — for example, Flyway or Liquibase.
3. Is reconciled with the Exposed model on the application side.

If the application uses schema validation or migration diff generation via Exposed, add:

Maven

```
<dependency>
    <groupId>org.jetbrains.exposed</groupId>
    <artifactId>exposed-migration-core</artifactId>
    <version>${exposed.version}</version>
</dependency>
<dependency>
    <groupId>org.jetbrains.exposed</groupId>
    <artifactId>exposed-migration-jdbc</artifactId>
    <version>${exposed.version}</version>
</dependency>
```

Gradle

```
dependencies {
    implementation "org.jetbrains.exposed:exposed-migration-core:$exposedVersion"
    implementation "org.jetbrains.exposed:exposed-migration-jdbc:$exposedVersion"
}
```

In Exposed 1.3.0, the full path `MigrationUtils.statementsRequiredForDatabaseMigration(...)` unconditionally reads metadata about `CHECK` constraints from `INFORMATION_SCHEMA.CHECK_CONSTRAINTS`. The current JDBC driver YDB does not provide this part of the metadata, so the full generic Exposed diff for YDB does not work completely.

A practical YDB-compatible path:

- Apply the schema using external migrations.
- Use Exposed table definitions as a description of the client model.
- Validate drift through compatible Exposed metadata paths:
  - Existing columns.
  - Existing secondary indexes.

The dialect repository has integration coverage for a scenario where the schema is created with raw SQL and then reconciled with the Exposed model without failing on unsupported metadata.

> **Note**
>
> If the schema was just changed by raw SQL, perform validation in a new transaction so that Exposed does not work with stale metadata cache.

Signed temporal types in DDL

`enableSignedDatetimes` refers exclusively to schema generation via Exposed DDL: it changes DDL names for the standard Exposed types `date()`, `datetime()`, and `timestamp()`. This flag itself does not change anything for existing tables or for runtime binding of individual columns.

> **Note**
>
> Since Exposed DDL is a test/dev path, the `enableSignedDatetimes` flag also primarily relates to tests and local development. In production, temporal types are fixed in versioned SQL migrations.

By default (`enableSignedDatetimes = false`), the standard Exposed temporal types appear in the generated `CREATE TABLE` as:

- `Date`
- `Datetime`
- `Timestamp`

If signed mode is needed in Exposed DDL, configure it in two places: enable `enableSignedDatetimes` on the dialect (this changes the DDL of standard temporal types) and add `forceSignedDatetimes=true` to the JDBC URL (this changes the binding on the driver side):

```
registerYdbDialect(enableSignedDatetimes = true)

val db = Database.connect(
    url = "jdbc:ydb:grpc://localhost:2136/local?forceSignedDatetimes=true",
    driver = "tech.ydb.jdbc.YdbDriver",
    databaseConfig = DatabaseConfig {
        defaultIsolationLevel = Connection.TRANSACTION_SERIALIZABLE
        defaultReadOnly = false
        useNestedTransactions = false
    }
)
```

In this mode, the standard Exposed types `date`, `datetime`, and `timestamp` will appear in the generated `CREATE TABLE` as `Date32`, `Datetime64`, and `Timestamp64`.

If you need explicit control of an individual column type, use the extensions `ydbDate(...)`, `ydbDate32(...)`, `ydbDatetime(...)`, `ydbDatetime64(...)`, `ydbTimestamp(...)`, and `ydbTimestamp64(...)`. They always generate DDL and bind the parameter via JDBC vendor code of exactly the type specified in the function name, regardless of `enableSignedDatetimes`.

If the JDBC URL already has other parameters, the flag must be added via `&forceSignedDatetimes=true`.

Limitations and specifics

- Exposed 1.3.0 does not provide a dialect hook for rendering a single-column `PRIMARY KEY` inside `CREATE TABLE`.
- therefore, the DDL path for YDB is implemented as a workaround via `createStatement()` and `createYdbStatement()`.
- each table created via Exposed DDL in YDB must have `PRIMARY KEY`.
- `SchemaUtils.createMissingTablesAndColumns(...)` and `spring.exposed.generate-ddl=true` require the same override `createStatement()`.
- ANSI `MERGE` is not supported.
- `upsert(where)` and PostgreSQL-like logic `ON CONFLICT DO UPDATE` are not supported.
- functional indexes are not supported.
- `GLOBAL UNIQUE` via `ALTER TABLE ... ADD INDEX ...` depends on the limitations of the specific YDB version.
- `LOCAL` indexes and column-oriented tables (`STORE = COLUMN`) are not supported first-class in the dialect; if necessary, they can be attached via arbitrary YQL in `createYdbStatement()` (test-only) — the dialect is oriented towards row-oriented OLTP tables.
- full generic diff via `MigrationUtils.statementsRequiredForDatabaseMigration(...)` in Exposed 1.3.0 for YDB does not work completely due to unsupported metadata on `CHECK` constraints.

Drizzle ORM

Drizzle ORM is a lightweight TypeScript ORM for Node.js with a type-safe query builder and a schema definition DSL.

YDB supports integration with Drizzle ORM through the `@ydbjs/drizzle-adapter` adapter, which is part of the YDB JavaScript/TypeScript SDK. The adapter provides the familiar Drizzle API and accounts for YDB specifics: primary keys, secondary and vector indexes, TTL, partitioning, and column families.

This page is a brief overview of the integration. The detailed guide covering all features (query builders, relational API, migrations, DDL, vector search) is available at ydb.js.org.

Requirements

- Node.js 20.19 or newer
- The `drizzle-orm` and `@ydbjs/drizzle-adapter` packages
- A running YDB instance

Installation

```
npm install @ydbjs/drizzle-adapter drizzle-orm
```

Connecting

Connection string

The simplest way is to pass a connection string to `createDrizzle()`. The adapter creates and manages the YDB driver itself.

```
import { createDrizzle } from '@ydbjs/drizzle-adapter'

const db = createDrizzle({
  connectionString: process.env['YDB_CONNECTION_STRING']!,
})
```

The connection string has the form `grpc://localhost:2136/local` (or `grpcs://` for a secure connection), specifying the server address, gRPC port, and the database path.

Existing SDK driver

If your application already uses a driver from `@ydbjs/core`, you can wrap it in `YdbDriver` and reuse the shared connection.

```
import { Driver } from '@ydbjs/core'
import { YdbDriver, createDrizzle } from '@ydbjs/drizzle-adapter'

const driver = new Driver('grpc://localhost:2136/local')
await driver.ready()
const db = createDrizzle({
  client: new YdbDriver(driver),
})
```

When the work is done, release the resources if the driver was created by the adapter:

```
db.$client.close?.()
```

Schema definition

Tables are described with `ydbTable()`. A primary key is required for every table.

```
import { integer, text, timestamp, ydbTable } from '@ydbjs/drizzle-adapter/schema'

export const users = ydbTable('users', {
  id: integer('id').primaryKey(),
  email: text('email').notNull().unique(),
  name: text('name'),
  createdAt: timestamp('created_at')
    .notNull()
    .$defaultFn(() => new Date()),
})
```

The adapter supports all the main YDB data types (`Bool`, integer and floating-point types, `Utf8`, `String`, `Uuid`, `Json`, date and time types, and others), as well as YDB-specific schema features: secondary and vector indexes, TTL, partitioning, and column families. The full list of types and options is provided in the schema guide.

CRUD operations

```
import { and, eq, like } from 'drizzle-orm'

// Insert
await db.insert(users).values({ id: 1, email: 'alice@example.com', name: 'Alice' }).execute()

// Select with filtering
const filteredUsers = await db
  .select({ userId: users.id, userName: users.name })
  .from(users)
  .where(and(eq(users.id, 1), like(users.email, '%@example.com')))
  .execute()

// Update
await db.update(users).set({ name: 'Alice Cooper' }).where(eq(users.id, 1)).execute()

// Delete
await db.delete(users).where(eq(users.id, 1)).execute()
```

The "insert or update" by primary key operation uses `onDuplicateKeyUpdate()`:

```
await db
  .insert(users)
  .values({ id: 1, email: 'alice_new@example.com', name: 'Alice Updated' })
  .onDuplicateKeyUpdate({ set: { name: 'Alice Updated' } })
  .execute()
```

Transactions

Transactions are started via `db.transaction()`. YDB access modes and isolation levels are supported, along with an idempotency flag for automatic retries on network errors.

```
import { eq } from 'drizzle-orm'
import { TransactionRollbackError } from 'drizzle-orm/errors'

try {
  await db.transaction(
    async (tx) => {
      // Check a precondition before modifying data
      const inviter = await tx.select().from(users).where(eq(users.id, 1)).execute()
      if (inviter.length === 0) {
        tx.rollback()
      }

      await tx.insert(users).values({ id: 4, email: 'delta@example.com' }).execute()
    },
    {
      accessMode: 'read write',
      isolationLevel: 'serializableReadWrite',
      idempotent: true,
    }
  )
} catch (error) {
  if (error instanceof TransactionRollbackError) {
    console.log('transaction was rolled back')
  }
}
```

Limitations

Keep in mind the following YDB and adapter specifics:

- The adapter is distributed in ESM format only.
- Nested transactions are not supported.
- Only YDB isolation levels are allowed (`serializableReadWrite`, `snapshotReadOnly`); other levels are not emulated.
- `references()` is stored as metadata for the relational API — YDB does not enforce foreign keys at the database level.

Vector search

Tool	Guide
LangChain	Guide
Mem0	Guide

LangChain

Integration of YDB with LangChain allows using YDB as a vector store for RAG applications.

This integration allows developers to efficiently manage, query, and retrieve vectorized data, which is the foundation for modern applications related to natural language processing, search, and data analysis. Using embedding models, users can create sophisticated systems capable of understanding and retrieving information based on semantic similarity.

The integration is available for Python and JavaScript.

Installation

To use this integration, install a local YDB. For more information, see Install and start YDB.

Also install the LangChain packages and an embedding model for the required language:

Python

```
pip install -qU langchain-ydb
pip install -qU langchain-huggingface
```

JavaScript

```
npm install @ydbjs/langchain @langchain/core
npm install @langchain/community @huggingface/transformers
```

Initialization

To create a vector store YDB, you need to specify an embedding model and connection parameters:

Python

```
from langchain_huggingface import HuggingFaceEmbeddings
from langchain_ydb.vectorstores import YDB, YDBSearchStrategy, YDBSettings

embeddings = HuggingFaceEmbeddings(model_name="sentence-transformers/all-mpnet-base-v2")

settings = YDBSettings(
    host="localhost",
    port=2136,
    database="/local",
    table="ydb_example",
    strategy=YDBSearchStrategy.COSINE_SIMILARITY,
)
vector_store = YDB(embeddings, config=settings)
```

JavaScript

```
import { HuggingFaceTransformersEmbeddings } from "@langchain/community/embeddings/huggingface_transformers";
import { YDBSearchStrategy, YDBVectorStore } from "@ydbjs/langchain";

const embeddings = new HuggingFaceTransformersEmbeddings({
  model: "sentence-transformers/all-mpnet-base-v2",
});

const vectorStore = new YDBVectorStore(embeddings, {
  connectionString: "grpc://localhost:2136/local",
  table: "ydb_example",
  strategy: YDBSearchStrategy.CosineSimilarity,
});
```

Managing the Vector Store

Once you have created a vector store, you can interact with it by adding and removing various items.

Adding Items

Prepare the documents for processing:

Python

```python
from uuid import uuid4

from langchain_core.documents import Document

uuids = [str(uuid4()) for _ in range(10)]
documents = [
    Document(
        page_content="I had chocolate chip pancakes and scrambled eggs for breakfast this morning.",
        metadata={"source": "tweet"},
        id=uuids[0],
    ),
    Document(
        page_content="The weather forecast for tomorrow is cloudy and overcast, with a high of 62 degrees.",
        metadata={"source": "news"},
        id=uuids[1],
    ),
    Document(
        page_content="Building an exciting new project with LangChain - come check it out!",
        metadata={"source": "tweet"},
        id=uuids[2],
    ),
    Document(
        page_content="Robbers broke into the city bank and stole $1 million in cash.",
        metadata={"source": "news"},
        id=uuids[3],
    ),
    Document(
        page_content="Wow! That was an amazing movie. I can't wait to see it again.",
        metadata={"source": "tweet"},
        id=uuids[4],
    ),
    Document(
        page_content="Is the new iPhone worth the price? Read this review to find out.",
        metadata={"source": "website"},
        id=uuids[5],
    ),
    Document(
        page_content="The top 10 soccer players in the world right now.",
        metadata={"source": "website"},
        id=uuids[6],
    ),
    Document(
        page_content="LangGraph is the best framework for building stateful, agentic applications!",
        metadata={"source": "tweet"},
        id=uuids[7],
    ),
    Document(
        page_content="The stock market is down 500 points today due to fears of a recession.",
        metadata={"source": "news"},
        id=uuids[8],
    ),
    Document(
        page_content="I have a bad feeling I am going to get deleted :(",
        metadata={"source": "tweet"},
        id=uuids[9],
    ),
]
```

Add the documents to the vector store:

```
ids = vector_store.add_documents(documents=documents)
```

JavaScript

```
import { Document } from "@langchain/core/documents";
import { randomUUID } from "node:crypto";

const uuids = Array.from({ length: 10 }, () => randomUUID());
const documents = [
  new Document({
    pageContent: "I had chocolate chip pancakes and scrambled eggs for breakfast this morning.",
    metadata: { source: "tweet" },
    id: uuids[0],
  }),
  new Document({
    pageContent: "The weather forecast for tomorrow is cloudy and overcast, with a high of 62 degrees.",
    metadata: { source: "news" },
    id: uuids[1],
  }),
  new Document({
    pageContent: "Building an exciting new project with LangChain - come check it out!",
    metadata: { source: "tweet" },
    id: uuids[2],
  }),
  new Document({
    pageContent: "Robbers broke into the city bank and stole $1 million in cash.",
    metadata: { source: "news" },
    id: uuids[3],
  }),
  new Document({
    pageContent: "Wow! That was an amazing movie. I can't wait to see it again.",
    metadata: { source: "tweet" },
    id: uuids[4],
  }),
  new Document({
    pageContent: "Is the new iPhone worth the price? Read this review to find out.",
    metadata: { source: "website" },
    id: uuids[5],
  }),
  new Document({
    pageContent: "The top 10 soccer players in the world right now.",
    metadata: { source: "website" },
    id: uuids[6],
  }),
  new Document({
    pageContent: "LangGraph is the best framework for building stateful, agentic applications!",
    metadata: { source: "tweet" },
    id: uuids[7],
  }),
  new Document({
    pageContent: "The stock market is down 500 points today due to fears of a recession.",
    metadata: { source: "news" },
    id: uuids[8],
  }),
  new Document({
    pageContent: "I have a bad feeling I am going to get deleted :(",
    metadata: { source: "tweet" },
    id: uuids[9],
  }),
];
```

Add the documents to the vector store:

```
const ids = await vectorStore.addDocuments(documents);
```

Deleting Items

Items are deleted from the vector store by ID using the `delete` function:

Python

```
vector_store.delete(ids=[ids[-1]])
```

JavaScript

```
await vectorStore.delete({ ids: [ids.at(-1)] });
```

Querying the Vector Store

After creating the vector store and adding the necessary documents, you can perform search queries during chain or agent execution.

Direct Query

Similarity Search

A simple similarity search can be performed as follows:

Python

```
results = vector_store.similarity_search(
    "LangChain provides abstractions to make working with LLMs easy",
    k=2,
)
for res in results:
    print(f"* {res.page_content} [{res.metadata}]")
```

JavaScript

```
const results = await vectorStore.similaritySearch(
  "LangChain provides abstractions to make working with LLMs easy",
  2,
);
for (const res of results) {
  console.log(`* ${res.pageContent} [${JSON.stringify(res.metadata)}]`);
}
```

Result:

```
* Building an exciting new project with LangChain - come check it out! [{'source': 'tweet'}]
* LangGraph is the best framework for building stateful, agentic applications! [{'source': 'tweet'}]
```

Similarity Search with Score

You can also perform a search with a score:

Python

```
results = vector_store.similarity_search_with_score(
    "Will it be hot tomorrow?",
    k=3,
)
for res, score in results:
    print(f"* [SIM={score:.3f}] {res.page_content} [{res.metadata}]")
```

JavaScript

```
const results = await vectorStore.similaritySearchWithScore(
  "Will it be hot tomorrow?",
  3,
);
for (const [res, score] of results) {
  console.log(`* [SIM=${score.toFixed(3)}] ${res.pageContent} [${JSON.stringify(res.metadata)}]`);
}
```

Result:

```
* [SIM=0.595] The weather forecast for tomorrow is cloudy and overcast, with a high of 62 degrees. [{'sourc
e': 'news'}]
* [SIM=0.212] I had chocolate chip pancakes and scrambled eggs for breakfast this morning. [{'source': 'twee
t'}]
* [SIM=0.118] Wow! That was an amazing movie. I can't wait to see it again. [{'source': 'tweet'}]
```

Filtering

Search using filters is performed as follows:

Python

```
results = vector_store.similarity_search_with_score(
    "What did I eat for breakfast?",
    k=4,
    filter={"source": "tweet"},
)
for res, _ in results:
    print(f"* {res.page_content} [{res.metadata}]")
```

JavaScript

```
const results = await vectorStore.similaritySearchWithScore(
  "What did I eat for breakfast?",
  4,
  { source: "tweet" },
);
for (const [res] of results) {
  console.log(`* ${res.pageContent} [${JSON.stringify(res.metadata)}]`);
}
```

Result:

```
* I had chocolate chip pancakes and scrambled eggs for breakfast this morning. [{'source': 'tweet'}]
* Wow! That was an amazing movie. I can't wait to see it again. [{'source': 'tweet'}]
* Building an exciting new project with LangChain - come check it out! [{'source': 'tweet'}]
* LangGraph is the best framework for building stateful, agentic applications! [{'source': 'tweet'}]
```

Query via Retriever Transformation

The vector store can be transformed into a retriever for simplified use in chains.

An example is shown below:

Python

```python
retriever = vector_store.as_retriever(
    search_kwargs={
        "k": 2,
        "filter": {"source": "news"},
    },
)
results = retriever.invoke("Stealing from the bank is a crime")
for res in results:
    print(f"* {res.page_content} [{res.metadata}]")
```

JavaScript

```javascript
const retriever = vectorStore.asRetriever({
  k: 2,
  filter: { source: "news" },
});
const results = await retriever.invoke("Stealing from the bank is a crime");
for (const res of results) {
  console.log(`* ${res.pageContent} [${JSON.stringify(res.metadata)}]`);
}
```

Result:

```
* Robbers broke into the city bank and stole $1 million in cash. [{'source': 'news'}]
* The stock market is down 500 points today due to fears of a recession. [{'source': 'news'}]
```

Mem0

Mem0 is a long-term memory layer for AI agents and LLM applications. Mem0 extracts meaningful facts about the user from conversations, stores them as embeddings, and on subsequent queries finds relevant memories by semantic similarity. This allows the agent to "remember" the user's preferences and context across sessions.

Integration with YDB allows using YDB as a vector store for Mem0 memory — without a separate specialized vector database. The integration works on top of LangChain: Mem0 supports LangChain vector stores as a backend, and YDB provides a compatible store via the `langchain-ydb` package.

> **Note**
>
> In addition to the vector store, Mem0 uses a language model (LLM) to extract facts from the conversation and an embedding model to vectorize them. The examples below use OpenAI models (requires the `OPENAI_API_KEY` environment variable), but any Mem0-supported provider will work.

Installation

To use this integration, install a local YDB. For more information, see Install and start YDB.

Install Mem0 and the YDB integration package with LangChain:

```
pip install -qU mem0ai langchain-ydb langchain-openai
```

Initialization

Create a YDB vector store using `langchain-ydb` and pass it to the Mem0 configuration with the `langchain` provider:

The key to OpenAI models is expected in the `OPENAI_API_KEY` environment variable — set it in advance in your environment or secret manager.

```
from langchain_openai import OpenAIEmbeddings
from langchain_ydb.vectorstores import YDB, YDBSearchStrategy, YDBSettings
from mem0 import Memory

embeddings = OpenAIEmbeddings(model="text-embedding-3-small")

vector_store = YDB(
    embeddings,
    config=YDBSettings(
        host="localhost",
        port=2136,
        database="/local",
        table="mem0_memories",
        strategy=YDBSearchStrategy.COSINE_SIMILARITY,
    ),
)

memory = Memory.from_config({
    "vector_store": {
        "provider": "langchain",
        "config": {"client": vector_store},
    },
    "embedder": {
        "provider": "langchain",
        "config": {"model": embeddings},
    },
})
```

Saving facts

Pass the conversation messages to Mem0 — the model will extract facts from them and save them to the YDB table. Memory is shared between users using `user_id`:

```
memory.add(
    [
        {"role": "user", "content": "Привет! Меня зовут Алиса, я работаю архитектором."},
        {"role": "assistant", "content": "Рада знакомству, Алиса!"},
        {"role": "user", "content": "Предпочитаю примеры на Python."},
    ],
    user_id="alice",
)
```

Memory search

Before forming a response, the agent searches for relevant memories — Mem0 performs a vector search in YDB and returns facts ordered by similarity:

```
results = memory.search("На каком языке показывать примеры?", user_id="alice")
for item in results["results"]:
    print(f"{item['score']:.3f}  {item['memory']}")
```

Result:

```
0.512  Prefers examples in Python
0.231  Works as an architect
```

Viewing and deletion

User memories can be retrieved or deleted entirely:

```python
# all user memories
for item in memory.get_all(user_id="alice")["results"]:
    print(item["memory"])

# delete all user memories
memory.delete_all(user_id="alice")
```

SQL Dialect Converter to YQL

The SQL Dialect Converter is a service that transforms SQL queries written in other dialects (PostgreSQL, MySQL, ClickHouse, and others) into YQL syntax. The service is designed to simplify the migration of existing queries to YDB and lower the entry barrier for developers already familiar with other DBMS.

The converter is used in the DBeaver plugin for YDB on the **Convert Dialect** tab. The user pastes a query in the source dialect, selects the dialect from the list, and receives a version of the same query in YQL.

Principle of Operation

The transformation is performed in three stages:

1. **Parsing the Source SQL.** The source query is parsed by a dialect-specific parser into an abstract syntax tree (AST) — a structure that describes the meaning of the query independently of the syntax.
2. **AST Transformation.** Constructions specific to the source dialect are replaced with their equivalents in YQL. For example, type casting functions, work with dates and strings, `LIMIT` / `OFFSET` operators, and `WITH` constructions are adapted to YQL rules.
3. **YQL Generation.** A textual representation of the query in YQL is generated from the modified AST.

The stages are performed using the SQLGlot library, which includes a separate dialect module for YDB. SQLGlot is an open-source SQL parser and transpiler that supports over twenty dialects. It acts as both the parser for the source query and the generator for YQL.

> **Warning**
>
> The source query is sent to an external HTTPS service. Do not send queries containing confidential data (personal data, trade secrets, identifiers of real objects in production) to the converter.

Supported Dialects

The list of source dialects is determined by the set supported by SQLGlot. Among the main ones:

- PostgreSQL;
- MySQL;
- ClickHouse;
- Microsoft SQL Server (T-SQL);
- Oracle;
- Snowflake;
- BigQuery;
- Presto / Trino;
- Spark SQL / Databricks;
- SQLite.

The up-to-date full list of dialects can be obtained via the converter's API or viewed in the SQLGlot sources. The target dialect is always YQL.

Supported Constructions

The converter covers typical constructions of analytical and OLTP queries:

- Selection operators: `SELECT`, `JOIN` (all types), `WHERE`, `GROUP BY`, `HAVING`, `ORDER BY`, `LIMIT`, `OFFSET`.
- Window functions (`OVER`, `PARTITION BY`, `ROWS BETWEEN`).
- Subqueries and CTE (`WITH`).
- Type casting (`CAST`, `::`), arithmetic and logical operations.
- Functions for strings, numbers, dates, and times — mapped to the closest equivalent in YQL.
- Aggregate functions (`COUNT`, `SUM`, `AVG`, `MIN`, `MAX`, and others).
- DML operations: `INSERT`, `UPDATE`, `DELETE` (taking into account YDB transaction features).

Limitations

Full automatic conversion is not always possible, as YQL and other SQL dialects differ in data models and operation semantics. In particular:

- **Dialect-specific functions.** Functions that do not have a direct equivalent in YQL (for example, PostgreSQL arrays, MySQL `JSON_EXTRACT` with special path syntax) are translated into approximate equivalents or left for manual refinement.
- **Stored procedures and triggers.** Not supported, as YDB uses a different code execution model in the database.
- **Specific DDL.** `CREATE TABLE` for complex types may require manual adjustments taking into account columnar and row tables in YDB.
- **Optimizer hints.** Ignored: the YDB optimizer has its own control mechanisms.

The conversion result should be considered a draft: complex queries require manual verification and adaptation before execution.

YDB CLI

The YDB CLI provides software for managing your data in YDB.

To use the YDB CLI, first install it and then set up the connection and authentication.

For a full description of YDB CLI commands, see the following articles of this section:

- List of objects.
- Getting information about schema objects.
- Working with directories.
- Query execution.
- Streaming table reads.
- Working with secondary indexes.
- Getting a list of DB endpoints.
- Load testing.

YDB CLI

The YDB CLI provides software for managing your data in YDB.

To use the YDB CLI, first install it and then set up the connection and authentication.

For a full description of YDB CLI commands, see the following articles of this section:

- List of objects.
- Getting information about schema objects.
- Working with directories.
- Query execution.
- Streaming table reads.
- Working with secondary indexes.
- Getting a list of DB endpoints.
- Load testing.

Installing the YDB CLI

Linux

To install the YDB CLI, run the command:

```
curl -sSL https://install.ydb.tech/cli | bash
```

The script will install the YDB CLI and add the executable file path to the `PATH` environment variable. It will also generate shell completion files and print instructions on how to enable tab completion for commands and options.

> **Note**
>
> The script will update the `PATH` variable only if you run it in the bash or zsh command shell. If you run the script in a different shell, add the path to the CLI to the `PATH` variable yourself.
>
> Shell completion for bash requires the `bash-completion` package to be installed.

> **Tip**
>
> If you use a non-standard shell configuration, you can source the generated completion files from any rc file. The files are located at `~/.local/share/ydb/completion.bash.inc` and `~/.local/share/ydb/completion.zsh.inc`, and are kept up to date automatically by `ydb update`.

To update the environment variables, restart the command shell.

macOS

To install the YDB CLI, run the command:

```
curl -sSL https://install.ydb.tech/cli | bash
```

The script will install the YDB CLI and add the executable file path to the `PATH` environment variable. It will also generate shell completion files and print instructions on how to enable tab completion for commands and options.

To update the environment variables, restart the command shell.

Windows

You can install the YDB CLI using:

PowerShell. To do this, run the command:

```
iex (New-Object System.Net.WebClient).DownloadString('https://install.ydb.tech/cli-windows')
```

Specify whether to add the executable file path to the `PATH` environment variable:

```
Add ydb installation dir to your PATH? [Y/n]
```

cmd. To do this, run the command:

```
@"%SystemRoot%\System32\WindowsPowerShell\v1.0\powershell.exe" -Command "iex ((New-Object System.Net.WebClien
t).DownloadString('https://install.ydb.tech/cli-windows'))"
```

Specify whether to add the executable file path to the `PATH` environment variable:

```
Add ydb installation dir to your PATH? [Y/n]
```

To update the environment variables, restart the command shell.

> **Note**
>
> The YDB CLI uses Unicode characters in the output of some commands. If these characters aren't displayed correctly in the Windows console, switch the encoding to UTF-8:
>
> ```
> chcp 65001
> ```

Connecting the CLI to and authenticating with a database

Most of the YDB CLI commands relate to operations on a YDB database and require establishing a connection to it to be executed.

The YDB CLI uses the following sources to determine the database to connect to and the authentication mode to use with it (listed in descending priority):

1. The command line.
2. The profile set in the `--profile` command-line option.
3. Environment variables.
4. The activated profile.

For the YDB CLI to try connecting to the database, these steps must result in the endpoint and database path.

If all the steps are completed, but the YDB CLI did not determine the authentication mode, requests will be sent to the YDB server without adding authentication data. This may let you successfully work with locally deployed YDB clusters that require no authentication. For all databases available over the network, such requests will be rejected by the server with an authentication error returned.

To learn about potential situations where the YDB CLI won't try to connect to the database, see the Error messages below.

Command line parameters

DB connection options in the command line are specified before defining the command and its parameters:

```
ydb <connection_options> <command> <command_options>
```

- `-e, --endpoint <endpoint>` is the endpoint, that is, the main connection parameter that allows finding a YDB server on the network. If no port is specified, port 2135 is used. If no protocol is specified, gRPCs (with encryption) is used in YDB CLI public builds.
- `-d, --database <database>` is the database path.
- `--no-discovery` means do not perform discovery (client balancing) for ydb cluster connection. If this option is set the user provided endpoint (by `-e` option) will be used to setup a connections.

The authentication mode and parameters are selected by setting one of the following options:

- `--token-file <filepath>`: Enables the **Access Token** authentication mode using the contents of the file specified in this option.
- `--yc-token-file <filepath>`: Enables the **Refresh Token** authentication mode using the contents of the file specified in this option.
- `--use-metadata-credentials` : The **Metadata** authentication mode is used.
- `--sa-key-file <filepath>`: Enables the **Service Account Key** authentication mode, where the key and other parameters are taken from the JSON file specified in this option.
- `--user <username>` : The username and password based authentication mode is used with the username set in this option value. Additionally , you can specify:
  - `--password-file <filename>` : The password is read from the specified file.
  - `--no-password` : Defines an empty password. The password will be requested interactively if none of the password identification options listed above are specified in the command line parameters.
- `--oauth2-key-file <filepath>` : Enables the **OAuth 2.0 token exchange** authentication mode, where the key and other parameters are taken from the JSON file specified in this option. The `--iam-endpoint` option sets the token exchange endpoint in the `<schema>://<host>:<port>/<path>` format (via the YDB CLI option, profile, or environment variable).

If several of the above options are set simultaneously in the command line, the CLI returns an error asking you to specify only one:

```
$ ydb --use-metadata-credentials --iam-token-file ~/.ydb/token scheme ls
More than one auth method were provided via options. Choose exactly one of them
Try "--help" option for more info.
```

When using authentication modes that involve token rotation along with regularly re-requesting them from IAM (**Refresh Token**, **Service Account Key**, or **OAuth 2.0 token exchange**), a special parameter can be set to indicate where the IAM service is located:

- `--iam-endpoint <URL>` : Sets the URL of the IAM service to request new tokens in authentication modes with token rotation. The default value is `"iam.api.cloud.yandex.net"`.

Parameters from the profile set by the command-line option

If a certain connection parameter is not specified in the command line when calling the YDB CLI, it tries to determine it by the profile set in the `--profile` command-line option.

In the profile, you can define most of the variables that have counterparts in the Command line parameters section. Their values are processed in the same way as command line parameters.

Parameters from environment variables

If you did not explicitly specify a profile or authentication parameters at the command line, the YDB CLI attempts to determine the authentication mode and parameters from the YDB CLI environment as follows:

- If the value of the `IAM_TOKEN` environment variable is set, the **Access Token** authentication mode is used, where this variable value is passed.
- Otherwise, if the value of the `YC_TOKEN` environment variable is set, the **Refresh Token** authentication mode is used and the token to transfer to the IAM endpoint is taken from this variable value when repeating the request.
- Otherwise, if the value of the `USE_METADATA_CREDENTIALS` environment variable is set to 1, the **Metadata** authentication mode is used.
- Otherwise, if the value of the `SA_KEY_FILE` environment variable is set, the **Service Account Key** authentication mode is used and the key is taken from the file whose name is specified in this variable.

- If the value of the `YDB_USER` or `YDB_PASSWORD` environment variable is set, the username and password based authentication mode is used. The username is read from the `YDB_USER` variable. If it is not set, an error saying `User password was provided without user name` is returned. The password is read from the `YDB_PASSWORD` variable. If it is not set, then, depending on whether the `--no-password` command-line option is specified, either an empty password is used or a password is requested interactively.
- Otherwise, if the `YDB_OAUTH2_KEY_FILE` environment variable value is set, the **OAuth 2.0 token exchange** authentication mode is used, and the token exchange parameters are taken from a JSON file specified in this variable. The `--iam-endpoint` option is used to set the token exchange endpoint in the `<schema>://<host>:<port>/<path>` format (via a YDB CLI option, profile, or environment variable).

Parameters from the activated profile

If some connection parameter could not be determined in the previous steps, and you did not explicitly specify a profile at the command line with the `--profile` option, the YDB CLI attempts to use the connection parameters from the activated profile.

Error messages

Errors before attempting to establish a DB connection

If the CLI completed all the steps listed at the beginning of this article but failed to determine the endpoint, the command terminates with the error `Missing required option 'endpoint'`.

If the CLI completed all the steps listed at the beginning of this article but failed to determine the database path, the command terminates with the error message `Missing required option 'database'`.

If the authentication mode is known, but the necessary additional parameters are not, the command is aborted and an error message describing the issue is returned:

- `(No such file or directory) util/system/file.cpp:857: can't open "<filepath>" with mode RdOnly|Seq (0x00000028)`: Couldn't open and read the file `<filepath>` specified in a parameter passing the file name and path.

Additional parameters

When using gRPCs (with encryption), you may need to select a root certificate.

- `--ca-file <filepath>`: Root certificate PEM file for a TLS connection.

Authentication

The YDB CLI `discovery whoami` auxiliary command lets you check the account that you actually used to authenticate with the server.

YDB CLI commands

General syntax for calling YDB CLI commands:

```
ydb [global options] <command> [<subcommand> ...] [command options]
```

where:

- `ydb` is the command to run the YDB CLI from the OS command line.
- `[global options]` are global options that are common for all YDB CLI commands.
- `<command>` is the command.
- `[<subcomand> ...]` are subcommands specified if the selected command contains subcommands.
- `[command options]` are command options specific to each command and subcommands.

Commands

You can learn about the necessary commands by selecting the subject section in the menu on the left or using the alphabetical list below.

Any command can be run from the command line with the `--help` option to get help on it. You can get a list of all commands supported by the YDB CLI by running the YDB CLI with the `--help` option, but without any command.

Command / subcommand	Brief description
admin cluster bridge failover	Emergency switchover when pile is unavailable
admin cluster bridge list	List state of each pile in bridge mode
admin cluster bridge rejoin	Returning pile to the cluster after maintenance or recovery
admin cluster bridge switchover	Planned `PRIMARY` pile change
admin cluster bridge takedown	Taking pile out of the cluster for maintenance
admin cluster config fetch	Getting the current dynamic configuration of the cluster
admin cluster config generate	Generating a dynamic configuration from a static startup configuration
admin cluster config replace	Replacing the cluster dynamic configuration
admin cluster config resolve	Computing the final cluster dynamic configuration based on the base configuration and override selectors
admin cluster config version	Displaying the cluster configuration version on nodes
admin cluster dump	Dumping cluster' metadata to the file system
admin cluster restore	Restoring cluster' metadata from the file system
admin database config fetch	Getting the current dynamic configuration of the database
admin database config generate	Generating a database dynamic configuration from a static startup configuration
admin database config replace	Replacing the database dynamic configuration
admin database config resolve	Computing the final database dynamic configuration based on the base configuration and override selectors
admin database config version	Displaying the database configuration version
admin database dump	Dumping database' data and metadata to the file system
admin database restore	Restoring database' data and metadata from the file system
admin node config init	Initializing node configuration
auth get-token	Getting an authentication token from authentication parameters
config info	Viewing connection parameters
	config profile activate
	config profile create
	config profile delete
	config profile deactivate
	config profile get
	config profile list
	config profile replace
	config profile set

Service commands

These commands have to do with the YDB CLI client itself and do not involve establishing a DB connection. They can be expressed either as a parameter or as an option.

Name	Description
`-?`, `-h`, `--help`	Output the YDB CLI syntax help
`version`	Output the YDB CLI version (for public builds)
`update`	Update the YDB CLI to the latest version (for public builds)
`config info`	Displaying connection parameters
`--license`	Show the license (for public builds)
`--credits`	Show third-party product licenses (for public builds)

If it is not known whether the used YDB CLI build is public, you can find out if a particular service command is supported through help output.

Global parameters

DB connection options

DB connection options are described in Connecting to and authenticating with a database.

Service options

- `--profile <name>`: Indicates the use of the DB connection profile with the specified name when executing a YDB CLI command. Most connection parameters can be stored in the profile.
- `-v, --verbose`: Prints detailed information about all operations being executed. Specifying this option is helpful when locating DB connection issues.
- `--profile-file`: Use profiles from the specified file. By default, profiles from the `~/.ydb/config/config.yaml` file are used.

table attribute add

With the `table attribute add` command, you can add a custom attribute to your table.

General format of the command:

```
ydb [global options...] table attribute add [options...] <table path>
```

- `global options`: Global parameters.
- `options`: Parameters of the subcommand.
- `table path`: The table path.

Look up the description of the command to add a custom attribute:

```
ydb table attribute add --help
```

Parameters of the subcommand

Name	Description
`--attribute`	The custom attribute in the `<key>=<value>` format. You can use `--attribute` many times to add multiple attributes by a single command.

Examples

Add the custom attributes with the keys `attr_key1`, `attr_key2` and the respective values `attr_value1`, `attr_value2` to the `my-table` table:

```
ydb table attribute add --attribute attr_key1=attr_value1 --attribute attr_key2=attr_value2 my-table
```

table attribute drop

With the `table attribute drop` command, you can drop a custom attribute from your table.

General format of the command:

```
ydb [global options...] table attribute drop [options...] <table path>
```

- `global options`: Global parameters.
- `options`: Parameters of the subcommand.
- `table path`: The table path.

Look up the description of the command to add a custom attribute:

```
ydb table attribute drop --help
```

Parameters of the subcommand

Name	Description
`--attributes`	The key of the custom attribute to be dropped. You can list multiple keys separated by a comma (`,`).

Examples

Drop the custom attributes with the keys `attr_key1` and `attr_key2` from the `my-table` table:

```
ydb table attribute drop --attributes attr_key1,attr_key2 my-table
```

List of objects

The `scheme ls` command lets you get a list of scheme objects in the database:

```
ydb [connection options] scheme ls [path] [-lR1]
```

where [connection options] are database connection options

Executing the command without parameters produces a compressed list of object names in the database's root directory.

In the `path` parameter, you can specify the directory you want to list objects in.

The following options are available for the command:

- `-l`: Full details about attributes of each object.
- `-R`: Recursive traversal of all subdirectories.
- `-1`: Output a single schema object per row (for example, to be later handled in a script).

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

- Getting objects from the root database directory in a compressed format

```
ydb --profile quickstart scheme ls
```

- Getting objects in all database directories in a compressed format

```
ydb --profile quickstart scheme ls -R
```

- Getting objects from the given database directory in a compressed format

```
ydb --profile quickstart scheme ls dir1
ydb --profile quickstart scheme ls dir1/dir2
```

- Getting objects in all subdirectories in the given directory in a compressed format

```
ydb --profile quickstart scheme ls dir1 -R
ydb --profile quickstart scheme ls dir1/dir2 -R
```

- Getting complete information on objects in the root database directory

```
ydb --profile quickstart scheme ls -l
```

- Getting complete information about objects in a given database directory

```
ydb --profile quickstart scheme ls dir1 -l
ydb --profile quickstart scheme ls dir2/dir3 -l
```

- Getting complete information about objects in all database directories

```
ydb --profile quickstart scheme ls -lR
```

- Getting complete information on objects in all subdirectories of a given database directory

```
ydb --profile quickstart scheme ls dir1 -lR
ydb --profile quickstart scheme ls dir2/dir3 -lR
```

Getting information about schema objects

Get information about a schema object:

```
ydb scheme describe episodes --stats
```

Result:

```
<table> episodes

┌─────────────┬──────────┬────────┬─────┐
| Name        | Type     | Family | Key |
├─────────────┼──────────┼────────┼─────┤
| air_date    | Uint64? |        |     |
| episode_id | Uint64? |        | K2  |
| season_id   | Uint64? |        | K1  |
| series_id   | Uint64? |        | K0  |

```

Permissions

General list of commands

You can get a list of available commands via interactive help:

```
ydb scheme permissions --help
```

```
Usage: ydb [global options...] scheme permissions [options...] <subcommand>

Description: Modify permissions

Subcommands:
permissions                Modify permissions
├─ chown                   Change owner
├─ clear                   Clear permissions
├─ grant                   Grant permission (aliases: add)
├─ list                    List permissions
├─ revoke                  Revoke permission (aliases: remove)
├─ set                     Set permissions
├─ clear-inheritance       Do not inherit permissions from the parent
└─ set-inheritance         Inherit permissions from the parent
```

All commands have an additional parameter, which is not critical for them:
`--timeout ms` - a technical parameter that sets the server response timeout.

grant, revoke

The `grant` and `revoke` commands allow you to establish and revoke, respectively, access rights to schema objects for a user or group of users. Essentially, they are analogues of the corresponding YQL GRANT and REVOKE commands.

The syntax of the YDB CLI commands is as follows:

```
ydb [connection options] scheme permissions grant  [options...] <path> <subject>
ydb [connection options] scheme permissions revoke [options...] <path> <subject>
```

Parameters:

`<path>` — the full path from the root of the cluster to the object whose rights need to be modified.
`<subject>` — the name of the user or group whose access rights are being changed.

Additional parameters `[options...]`:

`{-p|--permission} NAME` — the list of rights that need to be granted (`grant`) or revoked (`revoke`) for the user.

Each right must be passed as a separate parameter, for example:

```
ydb scheme permissions grant -p "ydb.access.grant" -p "ydb.generic.read" '/Root/db1/MyApp/Orders' testuser
```

set

The `set` command allows you to set access rights to schema objects for a user or group of users.

Command syntax:

```
ydb [connection options] scheme permissions set  [options...] <path> <subject>
```

The values of all parameters are identical to the `grant`, `revoke` commands. However, the key difference of the `set` command from `grant` and `revoke` is that it sets exactly those access rights to the specified object that are listed in the `-p (--permission)` parameters. Other rights for the specified user or group will be revoked.

For example, previously the user `testuser` was granted rights to the object `'/Root/db1'` such as `"ydb.granular.select_row"`, `"ydb.granular.update_row"`, `"ydb.granular.erase_row"`, `"ydb.granular.read_attributes"`, `"ydb.granular.write_attributes"`, `"ydb.granular.create_directory"`.
Then, as a result of executing the command, all rights to the specified object will be revoked (as if `revoke` was called for each of the rights) and only the right `"ydb.granular.select_row"` specified in the `set` command will remain:

```
ydb scheme permissions set -p "ydb.granular.select_row" '/Root/db1' testuser
```

list

The `list` command allows you to obtain the current list of access rights to schema objects.

Command syntax:

```
ydb [connection options] scheme permissions list [options...] <path>
```

Parameters:
`<path>` — the full path from the cluster's root to the object you want to get rights for.

Example result of executing `list`:

```
ydb scheme permissions list '/Root/db1/MyApp'
```

```
Owner: root

Permissions:
user1:ydb.generic.read

Effective permissions:
USERS:ydb.database.connect
METADATA-READERS:ydb.generic.list
DATA-READERS:ydb.granular.select_row
DATA-WRITERS:ydb.tables.modify
DDL-ADMINS:ydb.granular.create_directory,ydb.granular.write_attributes,ydb.granular.create_table,ydb.granula
r.remove_schema,ydb.granular.alter_schema
ACCESS-ADMINS:ydb.access.grant
DATABASE-ADMINS:ydb.generic.manage
user1:ydb.generic.read
```

The result structure consists of three blocks:

- `Owner` — shows the owner of the schema object.
- `Permissions` — displays a list of rights directly given to this object.
- `Effective permissions` — displays a list of rights that are effectively applied to this schema object, taking into account the rules of rights inheritance. This list also includes all the rights displayed in the `Permissions` section.

clear

The `clear` command allows you to revoke all previously granted rights to the schema object. Rights that apply to it by inheritance rules will continue to apply.

```
ydb [global options...] scheme permissions clear [options...] <path>
```

Parameters:
`<path>` — the full path from the root of the cluster to the object whose permissions need to be revoked.

For example, if you execute the command over the database state from the previous example `list`:

```
ydb scheme permissions clear '/Root/db1/MyApp'
```

And then execute the `list` command again on the object `/Root/db1/MyApp`, you will get the following result:

```
Owner: root

Permissions:
none

Effective permissions:
USERS:ydb.database.connect
METADATA-READERS:ydb.generic.list
DATA-READERS:ydb.granular.select_row
DATA-WRITERS:ydb.tables.modify
DDL-ADMINS:ydb.granular.create_directory,ydb.granular.write_attributes,ydb.granular.create_table,ydb.granula
r.remove_schema,ydb.granular.alter_schema
ACCESS-ADMINS:ydb.access.grant
DATABASE-ADMINS:ydb.generic.manage
```

Note that the `Permissions` section is now empty. This means all permissions for this object have been revoked. Also, there have been changes in the contents of the `Effective permissions` section: it no longer lists the permissions that were granted directly to the object `/Root/db1/MyApp`.

chown

The `chown` command allows you to change the owner of a schema object.

Command syntax:

```
ydb [connection options] scheme permissions chown [options...] <path> <owner>
```

Parameters:
`<path>` — the full path from the root of the cluster to the object whose permissions need to be modified.
`<owner>` — the name of the new owner (a user or a group) of the specified object.

Example of a `chown` command:

```
ydb scheme permissions chown '/Root/db1' testuser
```

> **Note**
>
> In the current version of YDB, there is a restriction that only the user who is the current owner of the schema object can change the owner.

clear-inheritance

The `clear-inheritance` command allows you to prohibit the inheritance of permissions for a schema object.

Command syntax:

```
ydb [connection options] scheme permissions clear-inheritance [options...] <path>
```

Parameters:
`<path>` — the full path from the cluster' root to the object whose permissions need to be modified.

Example of a `clear-inheritance` command:

```
ydb scheme permissions clear-inheritance '/Root/db1'
```

set-inheritance

The `set-inheritance` command allows you to enable permission inheritance for a schema object.

Command syntax:

```
ydb [connection options] scheme permissions set-inheritance [options...] <path>
```

Parameters:
`<path>` — the full path from the cluster's root to the object whose permissions need to be modified.

Example of a `set-inheritance` command:

```
ydb scheme permissions set-inheritance '/Root/db1'
```

Directories

The YDB database supports an internal directory structure that can host database objects.

YDB CLI supports operations to change the directory structure and to access schema objects by their directory name.

Creating a directory

The `scheme mkdir` command creates the directories:

```
ydb [connection options] scheme mkdir <path>
```

where [connection options] are database connection options

In the `path` parameter, specify the relative path to the directory being created, from the root database directory. This command creates all the directories that didn't exist at the path when the command was called.

If the destination directory had already existed at the path, then the command execution will be completed successfully (result code 0) with a warning that no changes have been made:

```
Status: SUCCESS
Issues:
<main>: Error: dst path fail checks, path: /<database>/<path>: path exist, request accepts it,
pathId: [OwnerId: <some>, LocalPathId: <some>], path type: EPathTypeDir, path state: EPathStateNoChanges
```

It also supports the syntax of a full path beginning with `/`. The full path must begin with the path to the database specified in the connection parameters or allowed by the current connection to the cluster.

Examples:

- Creating a directory at the database root

  ```
  ydb --profile quickstart scheme mkdir dir1
  ```

- Creating directories at the specified path from the database root

  ```
  ydb --profile quickstart scheme mkdir dir1/dir2/dir3
  ```

Deleting a directory

The `scheme rmdir` command deletes a directory:

```
ydb [global options...] scheme rmdir [options...] <path>
```

- `global options` : Global parameters.
- `options` : Parameters of the subcommand.
- `path` : Path to the deleted directory.

Look up the description of the directory deletion command:

```
ydb scheme rmdir --help
```

Parameters of the subcommand

Name	Description
`-r`, `--recursive`	This option deletes the directory recursively, which all its child objects (subdirectories, tables, topics). If you use this option, the confirmation prompt is shown by default.
`-f`, `--force`	Do not prompt for confirmation.
`-i`	Prompt for deletion confirmation on each object.
`-I`	Show a single confirmation prompt.
`--timeout <value>`	Operation timeout, ms.

If you try to delete a non-empty directory without the `-r` or `--recursive` option, the command fails with an error.

```
Status: SCHEME_ERROR
Issues:
<main>: Error: path table fail checks, path: /<database>/<path>: path has children, request
doesn't accept it, pathId: [OwnerId: <some>, LocalPathId: <some>], path type:
EPathTypeDir, path state: EPathStateNoChanges, alive children: <count>
```

Examples

- Deleting an empty directory:

  ```
  ydb scheme rmdir dir1
  ```

- Deleting an empty directory with a confirmation prompt:

```
ydb scheme rmdir -I dir1
```

- Recursively deleting a non-empty directory with a confirmation prompt:

```
ydb scheme rmdir -r dir1
```

- Recursively deleting a non-empty directory without a confirmation prompt:

```
ydb scheme rmdir -rf dir1
```

- Recursively deleting a non-empty directory, showing a confirmation prompt on each object:

```
ydb scheme rmdir -ri dir1
```

Using directories in other CLI commands

In all CLI commands to which the object name is passed by the parameter, it can be specified with a directory, for example, in `scheme describe`:

```
ydb --profile quickstart scheme describe dir1/table_a
```

The `scheme ls` command supports passing the path to the directory as a parameter:

```
ydb --profile quickstart scheme ls dir1/dir2
```

Using directories in YQL

Names of objects used in YQL queries may contain paths to directories hosting such objects. This path will be concatenated with the path prefix from the `TablePathPrefix` pragma. If the pragma is omitted, the object name is resolved relative to the database root.

Implicit creation of directories during import

The data import command creates a directory tree mirroring the original imported catalog.

Creating and deleting secondary indexes

By using the `table index` command, you can create and delete secondary indexes:

```
ydb [connection options] table index [subcommand] [options]
```

where [connection options] are database connection options

You can also add or delete a secondary index with the ADD INDEX and DROP INDEX directives of YQL ALTER TABLE.

To learn about secondary indexes and their use in application development, see Secondary indexes under "Recommendations".

Creating a secondary index

Secondary indexes are created with the `table index add` command:

```
ydb [connection options] table index add <sync-async> <table> \
  --index-name STR --columns STR [--cover STR]
```

Parameters:

`<sync-async>`: The type of the secondary index. Use `global-sync` to build an index updated synchronously or `global-async` to build an index updated asynchronously.

`<table>`: The path and name of the table you are building an index for

`--index-name STR`: A mandatory parameter that sets the name of the index. It is recommended that you specify the names of such indexes, so that the columns included in them can be identified. Index names are unique in the context of the table.

`--columns STR`: A required parameter that defines the columns used in the index and their order in the index key. Column names are separated by a comma, with no spaces. The index key will include both the columns listed and the columns from the table's primary key.

`--cover STR`: An optional parameter that defines the covering columns of the index. Their values won't be added to the index key, but will be written to the index. This enables you to retrieve the values when searching the index without accessing the table.

When the command is executed, the DBMS starts building the index in the background, and the pseudographics-formatted `id` field shows the operation ID, so you can retrieve its status by `operation get`. When the index is being built, you can abort the process using `operation cancel`.

To forget an index-building operation (either completed or terminated), use `operation forget`.

To retrieve the status of all index-building operations, use `operation list buildindex`.

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Adding a synchronous index built on the `air_date` column to the `episodes` table created previously:

```
ydb -p quickstart table index add global-sync episodes \
  --index-name idx_aired --columns air_date
```

Adding to the previously created `series` table an asynchronous index built on the `release_date` and `title` columns, copying to the index the `series_info` column value:

```
ydb -p quickstart table index add global-async series \
  --index-name idx_rel_title --columns release_date,title --cover series_info
```

Result (the actual operation id might differ):

```
┌──────────────────────────────────────┬───────┬────────┐
| id                                   | ready | status |
├──────────────────────────────────────┼───────┼────────┤
| ydb://buildindex/7?id=2814749869 | false |        |
└──────────────────────────────────────┴───────┴────────┘
```

Getting the operation status (use the actual operation id):

```
ydb -p quickstart operation get ydb://buildindex/7?id=281474976866869
```

Returned value:

```
┌──────────────────────────────────────┬───────┬─────────┬───────┬──────────┬──────────────────┬────────────┐
| id                                   | ready | status  | state | progress | table            | index      |
├──────────────────────────────────────┼───────┼─────────┼───────┼──────────┼──────────────────┼────────────┤
| ydb://buildindex/7?id=2814749869 | true  | SUCCESS | Done  | 100.00%  | /local/episodes | idx_aired |
└──────────────────────────────────────┴───────┴─────────┴───────┴──────────┴──────────────────┴────────────┘
```

Deleting the index-building details (use the actual operation id):

```
ydb -p quickstart operation forget ydb://buildindex/7?id=2814749869
```

Deleting a index

Indexes are deleted by the `table index drop` command:

```
ydb [connection options] table index drop <table> --index-name STR
```

Example

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Deleting the `idx_aired` index from the episodes table (see the index-building example above):

```
ydb -p quickstart table index drop episodes --index-name idx_aired
```

Renaming a secondary index

To rename secondary indexes, use the `table index rename` command:

```
ydb [connection options] table index rename <table> --index-name STR --to STR
```

If an index with the new name exists, the command returns an error.

To replace your existing index atomically, execute the rename command with the `--replace` option:

```
ydb [connection options] table index rename <table> --index-name STR --to STR --replace
```

Example

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Renaming the `idx_aired` index built on the episodes table (see the example of index creation above):

```
ydb -p quickstart table index rename episodes --index-name idx_aired --to idx_aired_renamed
```

Copying tables

Using the `tools copy` subcommand, you can create a copy of one or more DB tables. The copy operation leaves the source table unchanged while the copy contains all the source table data.

General format of the command:

```
ydb [global options...] tools copy [options...]
```

- `global options` : Global parameters.
- `options` : Parameters of the subcommand.

View a description of the command to copy a table:

```
ydb tools copy --help
```

Parameters of the subcommand

Parameter name	Parameter description
`--timeout`	The time within which the operation should be completed on the server.
`--item <property>=<value>,...`	Operation properties. You can specify the parameter more than once to copy several tables in a single transaction. Required properties: • `destination`, `dst`, `d`: Path to target table. If the destination path contains folders, they must be created in advance. No table with the destination name should exist. • `source`, `src`, `s`: Path to source table. Optional properties: • `omit-indexes`: If `true`, indexes are not copied (default: `false`).

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Create the `backup` folder in the DB:

```
ydb -p quickstart scheme mkdir backup
```

Copy the `series` table to a table called `series-v1`, the `seasons` table to a table called `seasons-v1`, and `episodes` to `episodes-v1` in the `backup` folder:

```
ydb -p quickstart tools copy --item destination=backup/series-v1,source=series --item destination=backup/seas
ons-v1,source=seasons --item destination=backup/episodes-v1,source=episodes
```

View the listing of objects in the `backup` folder:

```
ydb -p quickstart scheme ls backup
```

Result:

```
episodes-v1  seasons-v1  series-v1
```

Renaming a table

Using the `tools rename` subcommand, you can rename one or more tables at the same time, move a table to another directory within the same database, replace one table with another one within the same transaction.

General command format:

```
ydb [global options...] tools rename [options...]
```

- `global options` : Global parameters.
- `options` : Subcommand parameters.

View a description of the command to rename a table:

```
ydb tools rename --help
```

Subcommand parameters

A single run of the `tools rename` command executes a single rename transaction that may include one or more operations to rename different tables.

Parameter name	Parameter description
`--item <property>=<value>,...`	Description of the rename operation. Can be specified multiple times if multiple rename operations need to be executed within a single transaction. Required properties: • `source`, `src`, and `s`: Path to the source table. • `destination`, `dst`, and `d`: Path to the destination table. If the destination path contains folders, they must be created in advance. Advanced properties: • `replace`, `force`: Overwrite the destination table. If `True`, the destination table is overwritten with its data deleted. `False`: If the destination table exists, an error is returned and the entire rename transaction is canceled. Default value: `False`.
`--timeout <value>`	Operation timeout, ms.

When including multiple rename operations in a single `tools rename` call, they're executed in the specified order, but within a single transaction. This lets you rotate the table under load without data loss: the first operation is renaming the working table to the backup one and the second is renaming the new table to the working one.

Examples

- Renaming a single table:

  ```
  ydb tools rename --item src=old_name,dst=new_name
  ```

- Renaming multiple tables within a single transaction:

  ```
  ydb tools rename \
    --item source=new-project/main_table,destination=new-project/episodes \
    --item source=new-project/second_table,destination=new-project/seasons \
    --item source=new-project/third_table,destination=new-project/series
  ```

- Moving tables to a different directory:

  ```
  ydb tools rename \
    --item source=new-project/main_table,destination=cinema/main_table \
    --item source=new-project/second_table,destination=cinema/second_table \
    --item source=new-project/third_table,destination=cinema/third_table
  ```

- Replacing a table

  ```
  ydb tools rename \
    --item replace=True,source=pre-prod-project/main_table,destination=prod-project/main_table
  ```

- Rotating a table

  ```
  ydb tools rename \
    --item source=prod-project/main_table,destination=prod-project/main_table.backup \
    --item source=pre-prod-project/main_table,destination=prod-project/main_table
  ```

Setting TTL parameters

Use the `table ttl set` subcommand to set TTL for the specified table.

General format of the command:

```
ydb [global options...] table ttl set [options...] <table path>
```

- `global options`: Global parameters.
- `options`: Parameters of the subcommand.
- `table path`: The table path.

View a description of the TTL set command:

```
ydb table ttl set --help
```

Parameters of the subcommand

Name	Description
`--column`	The name of the column that will be used to calculate the lifetime of the rows. The column must have the numeric or date and time type. In case of the numeric type, the value will be interpreted as the time elapsed since the beginning of the Unix epoch. Measurement units must be specified in the `--unit` parameter.
`--expire-after`	Additional time before deleting that must elapse after the lifetime of the row has expired. Specified in seconds. The default value is `0`.
`--unit`	The value measurement units of the column specified in the `--column` parameter. It is mandatory if the column has the numeric type. Possible values: • `seconds (s, sec)`: Seconds. • `milliseconds (ms, msec)`: Milliseconds. • `microseconds (us, usec)`: Microseconds. • `nanoseconds (ns, nsec)`: Nanoseconds.
`--run-interval`	The interval for running the operation to delete rows with expired TTL. Specified in seconds. The minimum allowed interval is 15 minutes (900 seconds). The default value (`3600`) is a good starting point for working with a TTL-enabled table. When choosing `--run-interval`, balance the delay before expired data is physically removed against the extra load on the cluster. Too small an interval triggers deletion background tasks frequently and can noticeably increase CPU and I/O load, especially with large data volumes. Too large an interval, conversely, delays physical deletion of rows: expired data occupies disk space longer and may continue to participate in scans. Regardless of the `--run-interval` value, queries to the table may return rows with expired TTL.

Examples

Note

The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Set TTL for the `series` table

```
ydb -p quickstart table ttl set \
  --column createtime \
  --expire-after 3600 \
  --run-interval 1200 \
  series
```

Resetting TTL parameters

Use the `table ttl reset` subcommand to reset TTL for the specified table.

General format of the command:

```
ydb [global options...] table ttl reset <table path>
```

- `global options`: Global parameters.
- `table path`: The table path.

View the description of the TTL reset command:

```
ydb table ttl reset --help
```

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Reset TTL for the `series` table:

```
ydb -p quickstart table ttl reset \
  series
```

Deleting a table

Using the `table drop` subcommand, you can delete a specified table.

General format of the command:

```
ydb [global options...] table drop [options...] <table path>
```

- `global options`: Global parameters.
- `options`: Parameters of the subcommand.
- `table path`: The table path.

To view a description of the table delete command:

```
ydb table drop --help
```

Parameters of the subcommand

Name	Description
`--timeout`	The time within which the operation should be completed on the server.

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

To delete the table `series`:

```
ydb -p quickstart table drop series
```

Table schema inference from data files

You can use the `ydb tools infer csv` command to generate a `CREATE TABLE` statement from a CSV data file. This can be helpful when you want to import data into a database and the table has not been created yet.

Command syntax:

```
ydb [global options...] tools infer csv [options...] <input files...>
```

- `global options` – global options.
- `options` – subcommand options.

To get the most up-to-date information about the command, use the `--help` option:

```
ydb tools infer csv --help
```

Subcommand options

Option Name	Description
`-p, --path`	Database path to the table that should be created. Default: `table`.
`--columns`	Explicitly specifies table column names, as a comma-separated list.
`--gen-columns`	Explicitly indicates that table column names should be generated automatically (column1, column2, ...).
`--header`	Explicitly indicates that the first row in the CSV contains column names.
`--rows-to-analyze`	Number of rows to analyze. 0 means unlimited. Reading will stop as soon as this number of rows is read. Default: `500000`.
`--execute`	Execute the `CREATE TABLE` request immediately after generation.

Note

If none of the `--columns`, `--gen-columns`, or `--header` options are explicitly specified, the following algorithm is used:

The values of the first row in the file are checked for the following conditions:

- The values meet the requirements for column names.
- The types of the values in the first row are different from the data types in the other rows of the file.

If both conditions are met, the values from the first row are used as the table's column names. Otherwise, column names are generated automatically (as `column1`, `column2`, etc.). See the example below for more details.

Column type inference algorithm

For each column, the command determines the least general type that fits all its values. The most general type is `Text`: if any value in a column is a string (for example, `abc`), the entire column will be inferred as `Text`.

All integer values are inferred as `Int64` if they fit within the `Int64` range. If any value exceeds this range, the type is set to `Double`.

Floating-point numbers are always inferred as `Double`.

Current Limitation

The first column is always chosen as the primary key. You may need to change the primary key to one that is more appropriate for your use case. For recommendations, see Choosing a primary key.

Examples

Note

The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Column names in the first row, no options specified

The `key` and `value` values in the first row match the table column name requirements and do not match the data types in the other rows (`Int64` and `Text`).
So the command uses the first row of the file as column names.

```
$ cat data_with_header.csv
key,value
123,abc
456,def

ydb tools infer csv data_with_header.csv
CREATE TABLE table (
    key Int64,
    value Text,
    PRIMARY KEY (key) -- First column is chosen. Probably need to change this.
)
WITH (
    STORE = ROW -- or COLUMN
    -- Other useful table options to consider:
    --, AUTO_PARTITIONING_BY_SIZE = ENABLED
    --, AUTO_PARTITIONING_BY_LOAD = ENABLED
    --, UNIFORM_PARTITIONS = 100 -- Initial number of partitions
    --, AUTO_PARTITIONING_MIN_PARTITIONS_COUNT = 100
    --, AUTO_PARTITIONING_MAX_PARTITIONS_COUNT = 1000
);
```

Note

The `WITH` block lists some useful table options. Uncomment the ones you need and remove the rest as appropriate.

Column names in the first row, using `--header` option

In this example, the `key` and `value` values in the first row match the data types (`Text`) in the other rows.
In this case, without the `--header` option, the command would not use the first row of the file as column names but would generate column names automatically.
To use the first row as column names in this situation, use the `--header` option explicitly.

```
$ cat data_with_header_text.csv
key,value
aaa,bbb
ccc,ddd

ydb tools infer csv data_with_header_text.csv --header
CREATE TABLE table (
    key Text,
    value Text,
    PRIMARY KEY (key) -- First column is chosen. Probably need to change this.
)
WITH (
    STORE = ROW -- or COLUMN
    -- Other useful table options to consider:
    --, AUTO_PARTITIONING_BY_SIZE = ENABLED
    --, AUTO_PARTITIONING_BY_LOAD = ENABLED
    --, UNIFORM_PARTITIONS = 100 -- Initial number of partitions
    --, AUTO_PARTITIONING_MIN_PARTITIONS_COUNT = 100
    --, AUTO_PARTITIONING_MAX_PARTITIONS_COUNT = 1000
);
```

Explicit column list

```
cat ~/data_no_header.csv
123,abc
456,def

ydb tools infer csv -p newtable ~/data_no_header.csv --columns my_key,my_value
CREATE TABLE newtable (
    my_key Int64,
    my_value Text,
    PRIMARY KEY (my_key)
)
WITH (
    STORE = ROW -- or COLUMN
    -- Other useful table options to consider:
    --, AUTO_PARTITIONING_BY_SIZE = ENABLED
    --, AUTO_PARTITIONING_BY_LOAD = ENABLED
    --, UNIFORM_PARTITIONS = 100 -- Initial number of partitions
    --, AUTO_PARTITIONING_MIN_PARTITIONS_COUNT = 100
    --, AUTO_PARTITIONING_MAX_PARTITIONS_COUNT = 1000
);
```

Automatically generate column names

```
cat ~/data_no_header.csv
123,abc
456,def

ydb tools infer csv -p newtable ~/data_no_header.csv --gen-columns
CREATE TABLE newtable (
    column1 Int64,
    column2 Text,
    PRIMARY KEY (f0) -- First column is chosen. Probably need to change this.
)
WITH (
    STORE = ROW -- or COLUMN
    -- Other useful table options to consider:
    --, AUTO_PARTITIONING_BY_SIZE = ENABLED
    --, AUTO_PARTITIONING_BY_LOAD = ENABLED
    --, UNIFORM_PARTITIONS = 100 -- Initial number of partitions
    --, AUTO_PARTITIONING_MIN_PARTITIONS_COUNT = 100
    --, AUTO_PARTITIONING_MAX_PARTITIONS_COUNT = 1000
);
```

Executing generated statement using the `--execute` option

In this example, the `CREATE TABLE` statement is actually executed right after generation.

```
$ cat data_with_header.csv
key,value
123,abc
456,def

ydb -p quickstart tools infer csv data_with_header.csv --execute
Executing request:

CREATE TABLE table (
    key Int64,
    value Text,
    PRIMARY KEY (key) -- First column is chosen. Probably need to change this.
)
WITH (
    STORE = ROW -- or COLUMN
    -- Other useful table options to consider:
    --, AUTO_PARTITIONING_BY_SIZE = ENABLED
    --, AUTO_PARTITIONING_BY_LOAD = ENABLED
    --, UNIFORM_PARTITIONS = 100 -- Initial number of partitions
    --, AUTO_PARTITIONING_MIN_PARTITIONS_COUNT = 100
    --, AUTO_PARTITIONING_MAX_PARTITIONS_COUNT = 1000
);

Query executed successfully.
```

Query execution plan and AST

YDB provides two types of query plans: a logical plan and an execution plan. The logical plan is better suited for analyzing complex queries with many join operators. The execution plan is more detailed: it additionally shows the stages of the distributed plan and the connectors between them, which makes it more convenient for analyzing simple OLTP queries.

Query execution plans

You can display the execution plan via YDB CLI with the `explain` command:

```
ydb -p <profile_name> table query explain \
-q "SELECT season_id, episode_id, title
FROM episodes
WHERE series_id = 1
AND season_id > 1
ORDER BY season_id, episode_id
LIMIT 3"
```

The returned execution plan is shown below:

```
Query Plan:
ResultSet
└──Limit (Limit: 3)
└──<Merge>
└──TopSort (Limit: 3, TopSortBy: )
└──Filter (Predicate: Exist(item.season_id) And Exist(item.series_id))
└──TablePointLookup (ReadRange: [series_id (1), season_id (1, +∞), episode_id (-∞, +∞)], ReadColumns: [episod
e_id, season_id, title, series_id], Table: episodes)
Tables: [episodes]
```

In addition to the query execution plan, you can get an AST (abstract syntax tree).
The AST section contains a representation in the internal miniKQL language.

To display the AST, call `explain` with the `--ast` flag:

```
ydb -p <profile_name> table query explain \
-q "SELECT season_id, episode_id, title
FROM episodes
WHERE series_id = 1
AND season_id > 1
ORDER BY season_id, episode_id
LIMIT 3" --ast
```

The resulting AST:

```
Query AST:
(
(let $1 (KqpTable '"episodes" '"72075186224045943:83859" '"" '1))
(let $2 '('"episode_id" '"season_id" '"title" '"series_id"))
(let $3 (Uint64 '1))
(let $4 (KqpRowsSourceSettings $1 $2 '() '((KqlKeyExc $3 $3) (KqlKeyInc $3))))
(let $5 (Uint64 '"3"))
(let $6 (DqPhyStage '((DqSource (DataSource '"KqpReadRangesSource") $4)) (lambda '($12) (block '(
  (let $13 (Bool 'true))
  (return (FromFlow (TopSort (OrderedMap (OrderedFilter (ToFlow $12) (lambda '($14) (And (Exists (Member $14
'"season_id")) (Exists (Member $14 '"series_id"))))) (lambda '($15) (AsStruct '('"episode_id" (Member $15 '"e
pisode_id")) '('"season_id" (Member $15 '"season_id")) '('"title" (Member $15 '"title"))))) $5 '($13 $13) (la
mbda '($16) '((Member $16 '"season_id") (Member $16 '"episode_id"))))))
))) '('('"_logical_id" '842) '('"_id" '"14388682-e03b28dd-60f91f84-d7cd002f"))))
(let $7 (DqCnMerge (TDqOutput $6 '0) '('('"season_id" '"Asc") '('"episode_id" '"Asc"))))
(let $8 (DqPhyStage '($7) (lambda '($17) (FromFlow (Take (ToFlow $17) $5))) '('('"_logical_id" '855) '('"_id"
'"295c0459-34d4b026-b467e71f-35402430"))))
(let $9 '('"season_id" '"episode_id" '"title"))
(let $10 (DqCnResult (TDqOutput $8 '0) $9))
(let $11 (OptionalType (DataType 'Uint64)))
(return (KqpPhysicalQuery '((KqpPhysicalTx '($6 $8) '($10) '() '('('"type" '"data")))) '((KqpTxResultBinding
(ListType (StructType '('"episode_id" $11) '('"season_id" $11) '('"title" (OptionalType (DataType 'Strin
g))))) '0 '0)) '('('"type" '"data_query"))))
)
```

Logical query plan

Let's consider the analytical query Q18 from the TPCH benchmark:

```
$p = (
  select
    p.p_brand as p_brand,
    p.p_type as p_type,
    p.p_size as p_size,
    ps.ps_suppkey as ps_suppkey
  from
    part as p
  join
    partsupp as ps
on
    p.p_partkey = ps.ps_partkey
where
    p.p_brand <> 'Brand#45'
    and p.p_type not like 'MEDIUM POLISHED%'
    and (p.p_size = 49 or p.p_size = 14 or p.p_size = 23 or p.p_size = 45 or p.p_size = 19 or p.p_size = 3 or
p.p_size = 36 or p.p_size = 9)
);

$s = (
  select
    s_suppkey
  from
    supplier
  where
    s_comment like "%Customer%Complaints%"
);

$j = (
  select
    p.p_brand as p_brand,
    p.p_type as p_type,
    p.p_size as p_size,
    p.ps_suppkey as ps_suppkey
  from
    $p as p
  left only join
    $s as s
  on
    p.ps_suppkey = s.s_suppkey
);

select
    j.p_brand as p_brand,
    j.p_type as p_type,
    j.p_size as p_size,
    count(distinct j.ps_suppkey) as supplier_cnt
from
    $j as j
group by
    j.p_brand,
    j.p_type,
    j.p_size
order by
    supplier_cnt desc,
    p_brand,
    p_type,
    p_size
;
```

You can get the logical execution plan with the command:

```
ydb -p <profile_name> sql --explain -f q18.sql
```

This will result in a logical query plan consisting of the plan's operators and various optimizer predictions:

```
Query Plan:
┌────────────┬────────────┬────────────┬──────────────────────────────────────────────────────────────────────────────┐
| E-Cost     | E-Rows     | E-Size     | Operation                                                                    |
├────────────┼────────────┼────────────┼──────────────────────────────────────────────────────────────────────────────┤
|            |            |            | ┌> ResultSet                                                                 |
|            |            |            | └─┬> Sort ([row.supplier_cnt,row.p_brand,row.p_type,r                        |
|            |            |            | ow.p_size])                                                                  |
|            |            |            |   └─┬> Aggregate (Phase: Final)                                              |
|            |            |            |     └─┬> HashShuffle (KeyColumns: ["part.p_brand","pa                        |
|            |            |            | rt.p_size","part.p_type"], HashFunc: "HashV2")                               |
|            |            |            |       └─┬> Aggregate (GroupBy: [part.p_brand,part.p_s                        |
|            |            |            | ize,part.p_type], Aggregation: {Inc(_yql_agg_0)}, Pha                        |
|            |            |            | se: Intermediate)                                                            |
|            |            |            |         └─┬> Aggregate (Phase: Final)                                          |
|            |            |            |           └─┬> HashShuffle (KeyColumns: ["part.p_bran                        |
|            |            |            | d","part.p_size","part.p_type","partsupp.ps_suppkey"]                        |
|            |            |            | , HashFunc: "HashV2")                                                        |
|            |            |            |             └─┬> Aggregate (GroupBy: [part.p_brand,pa                        |
|            |            |            | rt.p_size,part.p_type,partsupp.ps_suppkey], Aggregati                        |

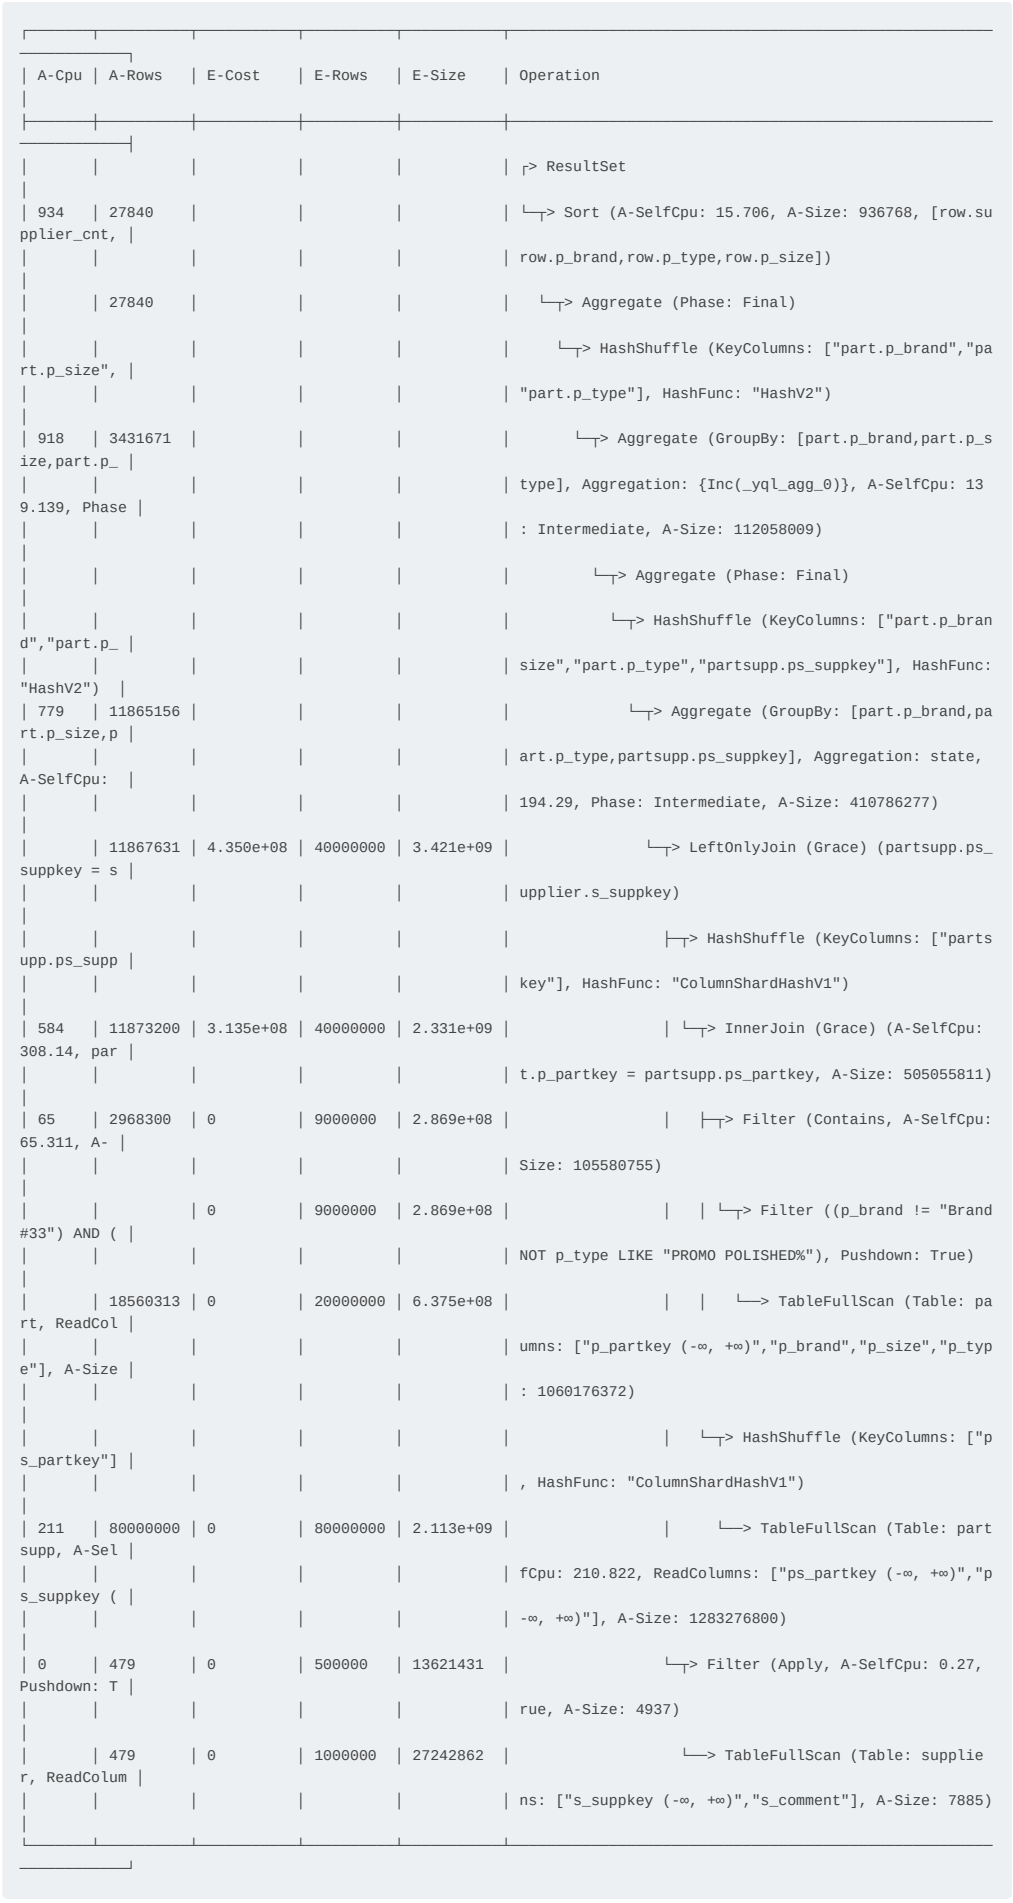
|            |            |            | s_partkey"], HashFunc: "ColumnShardHashV1")                                  |
| 0          | 80000000   | 2.113e+09  |                 |     └──> TableFullScan (Table: part                        |
|            |            |            | supp, ReadColumns: ["ps_partkey (-∞, +∞)","ps_suppkey                        |
|            |            |            |  (-∞, +∞)"])                                                                 |
| 0          | 500000     | 13621431   |                 └─┬> Filter (Apply, Pushdown: True)                           |
| 0          | 1000000    | 27242862   |                   └──> TableFullScan (Table: supplier                        |
|            |            |            | , ReadColumns: ["s_suppkey (-∞, +∞)","s_comment"])                           |
└────────────┴────────────┴────────────┴──────────────────────────────────────────────────────────────────────────────┘
```

This plan shows the operator tree YDB and three optimizer predictions for each operator:

- `E-Cost`: estimated cost of the current operator and all its inputs;
- `E-Rows`: estimated number of records at the output of the current operator;
- `E-Size`: estimated size of the operator's result in bytes.

In addition to optimizer predictions, you can also get actual statistics when executing the query:



- `A-Cpu`: total CPU time for the current operator;
- `A-Rows`: the actual number of records in the output of the current operator.

Execution statistics are not always available for each operator, as they are currently collected by execution stages. Several operators can be placed into a single stage.

To get a logical query plan with the execution statistics, run the following command:

```
ydb -p <profile_name> sql --explain-analyze --format pretty-table --analyze -f q18.sql
```

You will get the following logical query plan:

```
┌─────────┬────────────┬────────────┬────────────┬────────────┬──────────────
```

Streaming table reads

To read an entire table snapshot, use the `read` subcommand. Data is transferred as a stream, which enables you to read any size table.

Read data:

```
ydb table read episodes \
  --ordered \
  --limit 5 \
  --columns series_id,season_id,episode_id,title
```

Where:

- `--ordered`: Order read entries by key.
- `--limit`: Limit the number of entries to read.
- `--columns`: Columns whose values should be read (all by default) in CSV format.

Result:

```
┌───────────┬───────────┬────────────┬──────────────────────────────────┐
| series_id | season_id | episode_id | title                            |
├───────────┼───────────┼────────────┼──────────────────────────────────┤
| 1         | 1         | 1          | "Yesterday's Jam"                |
├───────────┼───────────┼────────────┼──────────────────────────────────┤
| 1         | 1         | 2          | "Calamity Jen"                   |
├───────────┼───────────┼────────────┼──────────────────────────────────┤
| 1         | 1         | 3          | "Fifty-Fifty"                    |
├───────────┼───────────┼────────────┼──────────────────────────────────┤
| 1         | 1         | 4          | "The Red Door"                   |
├───────────┼───────────┼────────────┼──────────────────────────────────┤
| 1         | 1         | 5          | "The Haunting of Bill Crouse"    |
└───────────┴───────────┴────────────┴──────────────────────────────────┘
```

To only get the number of read entries, use the `--count-only` parameter:

```
ydb table read episodes \
  --columns series_id \
  --count-only
```

Result:

```
70
```

Data export and import

YDB CLI contains a set of commands for exporting and importing data and descriptions of data schema objects. Data export can be used both for creating backups for subsequent recovery and for other purposes.

- Export file structure, used both when exporting to a file system and when exporting to an S3-compatible object storage.
- Exporting cluster metadata to a file system using `admin cluster dump`
- Importing cluster metadata from a file system using `admin cluster restore`
- Exporting database data and metadata to a file system using `admin database dump`
- Importing database data and metadata from a file system using `admin database restore`
- Exporting individual schema objects to a file system using `tools dump`
- Importing individual schema objects from a file system using `tools restore`
- Connection and authentication when working with an S3-compatible object storage
- Exporting to an S3-compatible object storage `export s3`
- Importing from an S3-compatible object storage `import s3`
- Configuring NFS for backup
- Exporting to NFS `export nfs`
- Importing from NFS `import nfs`

File structure of an export

The file structure outlined below is used to export data both to the file system and an S3-compatible object storage. When working with S3, the file path is added to the object key, and the key's prefix specifies the export directory. If a file is encrypted, additional `.enc` extension is added.

Cluster

> **Note**
>
> A cluster can be exported only to the file system.

A cluster corresponds to a directory in the file structure, which contains:

- Directories describing databases in the cluster, except:
  - Database schema objects
  - Database users and groups that are not administrators
- The `permissions.pb` file, which describes the cluster root ACL and its owner in text protobuf format
- The `create_user.sql` file, which describes the cluster users in YQL format
- The `create_group.sql` file, which describes the cluster groups in YQL format
- The `alter_group.sql` file, which describes user membership in the cluster groups in YQL format

Database

> **Note**
>
> You can export only database schema objects to an S3-compatible object storage.

A database corresponds to a directory in the file structure, which contains:

- Directories describing the database schema objects, for example, tables
- The `database.pb` file, which describes the database settings in text protobuf format
- The `permissions.pb` file, which describes the cluster root ACL and its owner in text protobuf format
- The `create_user.sql` file, which describes the cluster users in YQL format
- The `create_group.sql` file, which describes the cluster groups in YQL format
- The `alter_group.sql` file, which describes user membership in the cluster groups in YQL format

Schema mapping

When exporting data to S3-compatible object storage with a common prefix, a `SchemaMapping/mapping.json` file is generated. This file contains a list of schema objects in the export, mapped to the paths in the S3 storage.

For encrypted exports, this mapping serves two purposes: it anonymizes the original object names and stores additional metadata required for decryption.

The example of `SchemaMapping/mapping.json` file content:

```
{
    "exportedObjects": {
        "dir/table1": {
            "exportPrefix": "dir/table1"
        },
        "table2": {
            "exportPrefix": "table2"
        }
    }
}
```

Directories

Each database directory has a corresponding directory in the file structure. Each of them includes a `permissions.pb` file, which describes the directory ACL and owner in the text protobuf format. The directory hierarchy in the file structure mirrors the hierarchy in the database. If a database directory contains no items (neither tables nor subdirectories), directory in the file structure includes an empty file named `empty_dir`.

Tables

For each table in the database, there's a same-name directory in the file structure's directory hierarchy that includes:

- The `scheme.pb` file describing the table structure and parameters in the text protobuf format
- The `permissions.pb` file describes the table ACL and owner in the text protobuf format
- One or more `data_XX.csv` files with the table data in `csv` format, where `XX` is the file's sequence number. The export starts with the `data_00.csv` file, with a next file created whenever the current file exceeds 100 MB
- Directories describing the changefeeds. Directory names match the names of the changefeeds. Each directory contains the following files:
  - The `changefeed_description.pb` file describing the changefeed in the text protobuf format
  - The `topic_description.pb` file describing the underlying topic in the text protobuf format

Topics

For each topic in the database, there's a same-name directory in the file structure's directory hierarchy that includes the `create_topic.pb` file. This file provides information about the topic parameters, partitioning settings, and consumers in the text protobuf format.

Files with data

The format of data files is `.csv`, where each row corresponds to a record in the table (except the row with column headings). The urlencoded format is used for rows. For example, the file row for the table with the uint64 and utf8 columns that includes the number 1 and the Russian string "Привет" (translates to English as "Hi"), would look like this:

```
1,"%D0%9F%D1%80%D0%B8%D0%B2%D0%B5%D1%82"
```

Checksums

> **Note**
>
> File checksums are only generated when exporting to S3-compatible object storage.

YDB generates a checksum for each export file and saves it to a corresponding file with the `.sha256` suffix.

The file checksum can be validated using the `sha256sum` console utility:

```
$ sha256sum -c scheme.pb.sha256
scheme.pb: OK
```

Examples

Cluster

When you export a cluster containing a database named `/Root/db1` and a database named `/Root/db2`, the system will create the following file structure:

```
backup
├─ Root
│  ├─ db1
│  │  ├─ alter_group.sql
│  │  ├─ create_group.sql
│  │  ├─ create_user.sql
│  │  ├─ permissions.pb
│  │  └─ database.pb
│  └─ db2
│     ├─ alter_group.sql
│     ├─ create_group.sql
│     ├─ create_user.sql
│     ├─ permissions.pb
│     └─ database.pb
├─ alter_group.sql
├─ create_group.sql
├─ create_user.sql
└─ permissions.pb
```

Database

When you export a database containing a table named `episodes`, the system will create the following file structure:

```
├─ episodes
│     ├─ data00.csv
│     ├─ scheme.pb
│     └─ permissions.pb
├─ alter_group.sql
├─ create_group.sql
├─ create_user.sql
├─ permissions.sql
└─ database.pb
```

Tables

When you export the tables created under YDB Quick Start in Getting started, the system will create the following file structure:

```
├── episodes
│    ├── data_00.csv
│    ├── permissions.pb
│    └── scheme.pb
├── seasons
│    ├── data_00.csv
│    ├── permissions.pb
│    └── scheme.pb
└── series
     ├── data_00.csv
     ├── permissions.pb
     └── scheme.pb
     └── updates_feed
          └── changefeed_description.pb
          └── topic_description.pb
```

Contents of the `series/scheme.pb` file:

```
columns {
  name: "series_id"
  type {
    optional_type {
      item {
        type_id: UINT64
      }
    }
  }
}
columns {
  name: "title"
  type {
    optional_type {
      item {
        type_id: UTF8
      }
    }
  }
}
columns {
  name: "series_info"
  type {
    optional_type {
      item {
        type_id: UTF8
      }
    }
  }
}
columns {
  name: "release_date"
  type {
    optional_type {
      item {
        type_id: UINT64
      }
    }
  }
}
primary_key: "series_id"
storage_settings {
  store_external_blobs: DISABLED
}
column_families {
  name: "default"
  compression: COMPRESSION_NONE
}
```

Contents of the `series/update_feed/topic_description.pb` file:

```
retention_period {
  seconds: 86400
}
consumers {
  name: "my_consumer"
  read_from {
  }
  attributes {
    key: "_service_type"
    value: "data-streams"
  }
}
```

Directories

When you export an empty directory `series`, the system will create the following file structure:

```
└── series
    ├── permissions.pb
    └── empty_dir
```

When you export a directory `series` with the nested table `episodes`, the system will create the following file structure:

```
└── series
    ├── permissions.pb
    └── episodes
        ├── data_00.csv
        ├── permissions.pb
        └── scheme.pb
```

Exporting data to the file system

Cluster

The `admin cluster dump` command dumps the cluster' metadata to the client file system in the format described in the File structure of an export article:

```
ydb [connection options] admin cluster dump [options]
```

where [connection options] are database connection options

`[options]` – command parameters:

- `-o <PATH>` or `--output <PATH>` : Path to the directory in the client file system where the data will be dumped.
  If the directory doesn't exist, it will be created. However, the entire path to the directory must already exist.

  If the specified directory exists, it must be empty.

  If the parameter is omitted, the `backup_YYYYDDMMTHHMMSS` directory will be created in the current directory, where `YYYYDDMM` is the date and `HHMMSS` is the time when the dump process began, accroding to the system clock.

A cluster configuration is dumped separately using the `ydb admin cluster config fetch` command.

Database

The `admin database dump` command dumps the database' data and metadata to the client file system in the format described in File structure of an export:

Warning

Currently, this command does not process column tables. To export column tables, use the `export s3` command.

Warning

Currently, this command does not process secrets. You must create secrets manually during restore before restoring objects that use them, such as data transfers.

```
ydb [connection options] admin database dump [options]
```

where [connection options] are database connection options

`[options]` – command parameters:

- `-o <PATH>` or `--output <PATH>` : Path to the directory in the client file system where the data will be dumped.
  If the directory doesn't exist, it will be created. However, the entire path to the directory must already exist.

  If the specified directory exists, it must be empty.

  If the parameter is omitted, the `backup_YYYYDDMMTHHMMSS` directory will be created in the current directory, where `YYYYDDMM` is the date and `HHMMSS` is the time when the dump process began, accroding to the system clock.

A database configuration is dumped separately using the `ydb admin database config fetch` command.

Schema objects

The `tools dump` command dumps the schema objects to the client file system in the format described in File structure of an export:

Warning

Currently, this command does not process column tables. To export column tables, use the `export s3` command.

Warning

Currently, this command does not process secrets. You must create secrets manually during restore before restoring objects that use them, such as data transfers.

```
ydb [connection options] tools dump [options]
```

where [connection options] are database connection options

`[options]` – command parameters:

- `-o <PATH>` or `--output <PATH>` : Path to the directory in the client file system where the data will be dumped.
  If the directory doesn't exist, it will be created. However, the entire path to the directory must already exist.

  If the specified directory exists, it must be empty.

  If the parameter is omitted, the `backup_YYYYDDMMTHHMMSS` directory will be created in the current directory, where `YYYYDDMM` is the date and `HHMMSS` is the time when the dump process began, accroding to the system clock.

- `-p <PATH>` or `--path <PATH>` : Path to the database directory with objects or a path to the table to be dumped. The root database directory is used by default. The dump includes all subdirectories whose names don't begin with a dot and the tables in them whose names don't begin with a dot. To dump such tables or the contents of such directories, you can specify their names explicitly in this parameter.

- `--exclude <STRING>`: Template (PCRE) to exclude paths from export. Specify this parameter multiple times to exclude more than one template simultaneously.
- `--scheme-only`: Dump only the details of the database schema objects without dumping their data.
- `--consistency-level <VAL>`: The consistency level. Possible options:
  - `database`: A fully consistent dump, with one snapshot taken before starting the dump. Applied by default.
  - `table`: Consistency within each dumped table, taking individual independent snapshots for each table. Might run faster and have less impact on the current workload processing in the database.
- `--avoid-copy`: Do not create a snapshot before dumping. The default consistency snapshot might be inapplicable in some cases (for example, for tables with external blobs).
- `--save-partial-result`: Retain the result of a partial dump. Without this option, dumps that terminate with an error are deleted.
- `--preserve-pool-kinds`: If enabled, the `tools dump` command saves the storage device types specified for column groups of the tables to the dump (see the `DATA` parameter in Column groups for reference). To import such a dump, the same storage pools must be present in the database. If at least one storage pool is missing, the import procedure will end with an error. By default, this option is disabled, and the import procedure uses the default storage pool specified at the time of database creation (see Create a Database for reference).
- `--ordered`: Sorts rows in the exported tables by the primary key.

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Exporting a cluster

With automatic creation of the `backup_...` directory in the current directory:

```
ydb -e <endpoint> admin cluster dump
```

To a specific directory:

```
ydb -e <endpoint> admin cluster dump -o ~/backup_cluster
```

Exporting a database

To an automatically created `backup_...` directory in the current directory:

```
ydb -e <endpoint> -d <database> admin database dump
```

To a specific directory:

```
ydb -e <endpoint> -d <database> admin database dump -o ~/backup_db
```

Exporting a database schema objects

To an automatically created `backup_...` directory in the current directory:

```
ydb --profile quickstart tools dump
```

To a specific directory:

```
ydb --profile quickstart tools dump -o ~/backup_quickstart
```

Dumping the table structure within a specified database directory (including subdirectories)

```
ydb --profile quickstart tools dump -p dir1 --scheme-only
```

Importing data from the file system

Cluster

The `admin cluster restore` command restores a cluster from a backup on the file system. The backup must have been previously exported or prepared manually as described in the File structure of an export article:

```
ydb [connection options] admin cluster restore -i <PATH> [options]
```

where [connection options] are database connection options

The destination cluster must be running and initialized before it can be restored.

When restoring a cluster' metadata, databases and their administrators are created. Refer to Database for further details on restoring databases.

The restore operation requires that for each database to be restored, its database nodes must be available. You can start database nodes before running the restore command or while the restore operation is waiting for available nodes. If you encounter problems with available database nodes, you can restart the restore operation.

A cluster configuration is restored separately using the following steps:

1. Load the saved configuration using the `ydb admin cluster config replace` command.
2. Restart the cluster nodes.

Required parameters

`-i <PATH>` or `--input <PATH>`: Path to the directory in the client system from which the data will be imported.

Optional parameters

`[options]` – optional parameters of the command:

`--wait-nodes-duration <DURATION>`: The period of time that the restore command waits for available database nodes. Example: `10s`, `5m`, `1h`, `1.5d`, `30`. Duration can be expressed in weeks, days, hours, minutes, seconds, microseconds, nanoseconds. If no suffix is specified, the duration is seconds. The duration can be fractional. Combined duration like `1h30m` is not supported. If the duration is `0`, the restore command does not wait for available nodes.

Database

The `admin database restore` command restores the database from a backup on the file system. The backup must have been previously exported with the `admin database dump` command or prepared manually as described in the File structure of an export article:

> **Warning**
>
> Currently, this command does not restore column table data. To import column tables, use the `import s3` command with a backup created by `export s3`.

> **Warning**
>
> Currently, this command does not restore secrets (this data is not included in the backup). You must create secrets manually during restore before restoring objects that use them, such as data transfers.

```
ydb [connection options] admin database restore -i <PATH> [options]
```

where [connection options] are database connection options

The restore operation requires that for each database to be restored, its database nodes must be available. You can start database nodes before running the restore command or while the restore operation is waiting for available nodes. If you encounter problems with available database nodes, you can restart the restore operation.

Restoring database schema objects follows the same process described in Schema objects.

Database configuration is restored separately using the following steps:

1. Load the saved configuration using the `ydb admin database config replace` command.
2. Restart the database nodes.

Required parameters

`-i <PATH>` or `--input <PATH>`: Path to the directory in the client system from which the data will be imported.

Optional parameters

`[options]` – optional parameters of the command:

`--wait-nodes-duration <DURATION>`: The period of time that the restore command waits for available database nodes. Example: `10s`, `5m`, `1h`, `1.5d`, `30`. Duration can be expressed in weeks, days, hours, minutes, seconds, microseconds, nanoseconds. If no suffix is specified, the duration is seconds. The duration can be fractional. Combined duration like `1h30m` is not supported. If the duration is `0`, the restore command does not wait for available nodes.

Schema objets

The `tools restore` command creates the items of the database schema in the database, and populates them with the data previously exported there with the `tools dump` command or prepared manually as per the rules from the File structure of an export article:

Warning

Currently, this command does not restore column table data. To import column tables, use the `import s3` command with a backup created by `export s3`.

Warning

Currently, this command does not restore secrets (this data is not included in the backup). You must create secrets manually during restore before restoring objects that use them, such as data transfers.

```
ydb [connection options] tools restore -p <PATH> -i <PATH> [options]
```

where [connection options] are database connection options

If the table or directory already exists in the database, no changes will be made to its schema and ACL. If some columns present in the imported files are missing in the database or have mismatching types, this may lead to the data import operation failing.

To import data to the table, use the YQL `REPLACE` command. If the table included any records before the import, the records whose keys are present in the imported files are replaced by the data from the file. The records whose keys are absent in the imported files aren't affected.

Required parameters

- `-p <PATH>` or `--path <PATH>`: Path to the database directory the data will be imported to. To import data to the root directory, specify `.`. All the missing directories along the path will be created.
- `-i <PATH>` or `--input <PATH>`: Path to the directory in the client system from which the data will be imported.

Optional parameters

`[options]` – optional parameters of the command:

- `--restore-data <VAL>`: Enables/disables data import, 1 (yes) or 0 (no), defaults to 1. If set to 0, the import only creates items in the schema without populating them with data. If there's no data in the file system (only the schema has been exported), it doesn't make sense to change this option.
- `--restore-indexes <VAL>`: Enables/disables import of indexes, 1 (yes) or 0 (no), defaults to 1. If set to 0, the import won't either register indexes in the data schema or populate them with data.
- `--restore-acl <VAL>`: Enables/disables import of ACL, 1 (yes) or 0 (no), defaults to 1. If set to 0, the import creates items in the schema with an empty ACL, and their owner will be the user who started the import.
- `--replace-sys-acl <VAL>`: Enables/disables replacement of ACL for system objects, 1 (yes) or 0 (no), defaults to 1.
- `--dry-run`: Matching the data schemas in the database and file system without updating the database, 1 (yes) or 0 (no), defaults to 0. When enabled, the system checks that:
  - All tables in the file system are present in the database
  - These items are based on the same schema, both in the file system and in the database
- `--save-partial-result`: Save the partial import result. If disabled, an import error results in reverting to the database state before the import.
- `--import-data`: Use ImportData, a more efficient method for uploading data than the default approach. This method sends data to the server partitioned by the client and in a lighter format. However, it returns an error when attempting to import exported data into an existing table that already has indexes or is in the process of building them. To restore a table with indexes, ensure they are not already present in the schema (for example, using the `ydb scheme ls` command). By default, ImportData is disabled.
- `--replace`: Remove existing objects from the database that match those in the backup before restoration. Objects present in the backup but missing in the database are restored as usual; removal is skipped. If both `--replace` and `--verify-existence` are specified, restoration stops with an error when the first such object is found.
- `--verify-existence`: Use with `--replace` option to report an error if an object in the backup is missing from the database instead of silently skipping its removal.
- `--retries`: Number of retries for every upload data request. By default: `10`.

Workload restriction parameters

Using the below parameters, you can limit the import workload against the database.

Attention!

Some of the below parameters have default values. This means that the workload will be limited even if none of them is mentioned in `tools restore`.

- `--rps <VAL>`: Limits the number of queries used to upload batches to the database per second, the default value is 30.
- `--bandwidth <VAL>`: Limit the workload per second, defaults to 0 (not set). `<VAL>` specifies the data amount with a unit, for example, 2MiB. If this value is set, the `--rps` limit (see above) is not applied.
- `--in-flight <VAL>`: Limits the number of queries that can be run in parallel, the default value is 10. To achieve maximum parallelism, set the parameter value to the number of cores allocated for the restore process.
- `--upload-batch-rows <VAL>`: Limits the number of records in the uploaded batch, the default value is 0 (unlimited). `<VAL>` determines the number of records and is set as a number with an optional unit, for example, 1K.
- `--upload-batch-bytes <VAL>`: Limits the batch size of uploaded data, the default value is 512KB. `<VAL>` specifies the data amount with a unit, for example, 1MiB. Maximum value is 16 MiB.
- `--upload-batch-rus <VAL>`: Applies only to Serverless databases to limit Request Units (RU) that can be consumed to upload one batch, defaults to 30 RU. The batch size is selected to match the specified value. `<VAL>` determines the number of RU and is set as a number with an optional unit, for example, 100 or 1K.

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Restoring cluster

From the current file system directory:

```
ydb -e <endpoint> admin cluster restore -i .
```

From the specified file system directory:

```
ydb -e <endpoint> admin cluster restore -i ~/backup_cluster
```

Restoring database

From the current file system directory:

```
ydb -e <endpoint> -d <database> admin database restore -i .
```

From the specified file system directory:

```
ydb -e <endpoint> -d <database> admin database restore -i ~/backup_db
```

Importing schema objets to the database root

From the current file system directory:

```
ydb -p quickstart tools restore -p . -i .
```

From the current file system directory:

```
ydb -p quickstart tools restore -p . -i ~/backup_quickstart
```

Uploading data to the specified directory in the database

From the current file system directory:

```
ydb -p quickstart tools restore -p dir1/dir2 -i .
```

From the current file system directory:

```
ydb -p quickstart tools restore -p dir1/dir2 -i ~/backup_quickstart
```

Matching schemas between the database and file system:

```
ydb -p quickstart tools restore -p dir1/dir2 -i ~/backup_quickstart --dry-run
```

Example options for better performance

```
ydb -p quickstart tools restore -p . -i . --import-data --bandwidth=10GiB --in-flight=16 --upload-batch-bytes
=16MiB
```

Connecting to S3-compatible object storages

The commands used to export data from S3-compatible storages, `export s3` and `import s3`, use the same parameters for S3 connection and authentication. To learn how to get these parameters for certain cloud providers, see Getting S3 connection parameters below.

Connecting

To connect with S3, you need to specify an endpoint and bucket:

`--s3-endpoint HOST`: An S3 endpoint. `HOST`: A valid host name, such as: `storage.yandexcloud.net`

`--bucket STR`: An S3 bucket. `STR`: A string containing the bucket name

Authentication

Except when you import data from a public bucket, to connect, log in with an account that has write access to the bucket (for export to it) and read access to the bucket (for import from it).

You need two parameters to authenticate with S3:

- Access key ID (`--access-key`).
- Secret access key (`--secret-key`).

The YDB CLI takes values of these parameters from the following sources (listed in descending priority):

1. The command line.
2. Environment variables.
3. The `~/.aws/credentials` file.

Command line parameters

- `--access-key`: Access key ID.
- `--secret-key`: Secret access key.
- `--aws-profile`: Profile name from the `~/.aws/credentials` file. The default value is `default`.

Environment variables

If a certain authentication parameter is omitted in the command line, the YDB CLI tries to retrieve it from the following environment variables:

- `AWS_ACCESS_KEY_ID`: Access key ID.
- `AWS_SECRET_ACCESS_KEY`: Secret access key.
- `AWS_PROFILE`: Profile name from the `~/.aws/credentials` file.

AWS authentication file

If a certain authentication parameter is omitted in the command line and cannot be retrieved from an environment variable, the YDB CLI tries to get it from the specified profile or the default profile in the `~/.aws/credentials` file used for authenticating the AWS CLI. You can create this file with the `aws configure` AWS CLI command.

Getting the S3 connection parameters

Yandex.Cloud

Below is an example of getting access keys for the Yandex.Cloud Object Storage using the Yandex.Cloud CLI.

1. Install and set up the Yandex.Cloud CLI.
2. Use the following command to get the ID of your cloud folder (`folder-id`) (you'll need to add it to the commands below):

   ```
   yc config list
   ```

   The ID of your cloud folder is in the `folder-id:` line in the result:

   ```
   folder-id: b2ge70qdcff4bo9q6t19
   ```

3. To create a service account, run the command:

   ```
   yc iam service-account create --name s3account
   ```

   You can indicate any account name instead of `s3account`, or use your existing account name (be sure to replace it when copying the commands below).

   Account id will be printed on creation.

   To get the id of an existing account, use this command:

   ```
   yc iam service-account get --name <account-name>
   ```

4. Grant roles to your service account according to your intended S3 access level by running the command:

   Read (to import data to the YDB database)

   ```
   yc resource-manager folder add-access-binding <folder-id> \
     --role storage.viewer --subject serviceAccount:<s3-account-id>
   ```

Write (to export data from the YDB database)

```
yc resource-manager folder add-access-binding <folder-id> \
  --role storage.editor --subject serviceAccount:<s3-account-id>
```

Where `<folder-id>` is the cloud folder ID that you retrieved at step 2 and `<s3-account-id>` is the id of the account you created at step 3.

You can also read a full list of Yandex.Cloud roles.

5. Get static access keys by running the command:

```
yc iam access-key create --service-account-name s3account
```

If successful, the command will return the access_key attributes and the secret value:

```
access_key:
  id: aje6t3vsbj8lp9r4vk2u
  service_account_id: ajepg0mjt06siuj65usm
  created_at: "2018-11-22T14:37:51Z"
  key_id: 0n8X6WY6S24N7OjXQ0YQ
secret: JyTRFdqw8t1kh2-OJNz4JX5ZTz9Dj1rI9hxtzMP1
```

In this result:

- `access_key.key_id` is the access key ID (`--access-key`).
- `secret` is the secret access key (`--secret-key`).

Export to S3-compatible storage

The `export s3` command starts a server-side process of exporting data and schema object information to an S3-compatible storage in the format described in the article File structure:

```
ydb [connection options] export s3 [options]
```

where [connection options] are database connection options

Warning

Export is available only for objects of the following types:

- directory.
- row table.
- column table.
- secondary index.
- vector index.
- full-text index.
- topic (schema only).
- view.
- asynchronous replication.
- transfer.
- external data source.
- external table.

Note

As an alternative, you can export individual tables to an S3-compatible data storage using external data sources. For more details, see the article Exporting data to S3 object storage.

Command line parameters

`[options]` — command parameters:

S3 parameters

The export to S3 command requires specifying S3 connection parameters. Since the export is performed asynchronously by the YDB server, the specified endpoint must be accessible for establishing a connection from the server side.

`--destination-prefix PREFIX`: Key prefix in the S3 bucket.

List of exported objects

`--root-path PATH`: Root directory for exported objects. If not specified, the root directory of the database is used.

`--include PATH`: Data schema objects to include in the export. Directories are traversed recursively. Paths are specified relative to `root-path`. This parameter can be specified multiple times to include multiple objects. If not specified, all non-system objects in `root-path` are exported.

`--exclude STRING`: Pattern (PCRE) to exclude paths from the export. Paths are specified relative to `root-path`. This parameter can be specified multiple times for different patterns.

Alternative method

An alternative way to specify the list of objects is supported:

`--item STRING`: Description of the export object. The `--item` parameter can be specified multiple times if you need to export several objects. `STRING` is specified in the `<property>=<value>,...` format, with the following required properties:

- `source`, `src`, or `s` — path to the exported directory or table; `.` points to the root directory of the database. When specifying a directory, all non-system objects in it are exported, as well as all non-system subdirectories recursively.
- `destination`, `dst`, or `d` — path (key prefix) in S3 for placing the exported objects.

`--exclude STRING`: Pattern (PCRE) to exclude paths from export. This parameter can be specified multiple times for different patterns.

Warning

Exports made using alternative syntax will not contain a list of objects in the backup, so some features may be unavailable for them (in particular, encrypted backups), and import is only possible using the corresponding alternative import syntax.

Additional parameters

Parameter	Description
`--description STRING`	Text description of the operation, saved in the operation history.
`--retries NUM`	Number of retry attempts for export that the server will make. Default value: `10`.

`--compression STRING`	Compress exported data. With the default compression level for the Zstandard algorithm, data can be compressed by 5-10 times. Data compression uses CPU resources and may affect the speed of other database operations. Allowed values: • `zstd` — compression using the Zstandard algorithm with the default compression level (`3`); • `zstd-N` — compression using the Zstandard algorithm, `N` — compression level (`1` — `22`).
`--encryption-algorithm ALGORITHM`	Encrypt exported data using the specified algorithm. Supported values: `AES-128-GCM` , `AES-256-GCM` , `ChaCha20-Poly1305` .
`--encryption-key-file PATH`	Path to the file containing the encryption key (only for encrypted exports). This file is binary and must contain the exact number of bytes corresponding to the key length in the selected encryption algorithm (16 bytes for `AES-128-GCM` , 32 bytes for `AES-256-GCM` and `ChaCha20-Poly1305`). The key can also be passed via the `YDB_ENCRYPTION_KEY` environment variable, in hexadecimal string representation.
`--format STRING`	Output format. Allowed values: • `pretty` — human-readable format (default); • `proto-json-base64` — Protocol Buffers in JSON format, binary strings encoded in Base64.

Running the export

Server export operation flow

1. A server asynchronous export operation is created.
2. In the root directory of the database, a service directory `export-{id}` is created, where `{id}` is the numeric operation ID.
3. A consistent copy of the tables is created in this directory using the `CopyTables` mechanism.
4. The data of each table is written from the copy to the storage in the export file structure format, with parallel writing from different cluster nodes.
5. After successful completion, the service directory `export-{id}` and the table copies are deleted.

Launch result

Upon successful execution, the `export s3` command outputs summary information about the queued export operation to S3, in the format specified by the `--format` option. The actual export is performed asynchronously by the server. The summary information includes the operation ID, which can be used later to check the status and perform actions on the operation:

- In the `pretty` output mode (default), the operation ID is shown in the id field highlighted with pseudographics:

```
┌──────────────────────────────────────────────┬───────┬─────...
| id                                           | ready | stat...
├──────────────────────────────────────────────┼───────┼─────...
| ydb://export/6?id=281474976788395&kind=s3 | true  | SUCC...
├----------------------------------------------┴-------┴-----...
| StorageClass: NOT_SET
| Items:
...
```

- In the `proto-json-base64` output mode, the identifier is in the "id" attribute:

```
{"id":"ydb://export/6?id=281474976788395&kind=s3","ready":true, ... }
```

Export status

Data export runs in the background. You can get information about the status and progress of the export by calling the `operation get` command, which must be passed the **quoted** operation ID, for example:

```
ydb -p quickstart operation get "ydb://export/6?id=281474976788395&kind=s3"
```

The output format `operation get` is also set by the `--format` option.

Although the operation ID is in URL format, it is not guaranteed to be preserved in the future. It should be interpreted only as a string.

Completion of the export is tracked by changes in the "progress" attribute:

- In the `pretty` output mode (default), a successfully completed operation is reflected by the value "Done" in the `progress` field highlighted with pseudographics:

```
┌──────  ...  ──┬────────┬──────────┬────────────┬...
| id            | ready | status   | progress | ...
├──────...  ──┼────────┼──────────┼────────────┼...
| ydb://...     | true  | SUCCESS | Done       | ...
├-----  ...  --┴-------┴---------┴----------┴ ...
...
```

- In the `proto-json-base64` output mode, a completed operation is reflected by the value `PROGRESS_DONE` of the `progress` attribute:

```
{"id":"ydb://...", ...,"progress":"PROGRESS_DONE",... }
```

Completing the export operation

After completing the export, use the `operation forget` command to mark the export as completed (removed from the list of operations):

```
ydb -p quickstart operation forget "ydb://export/6?id=2814749767883 95&kind=s3"
```

List of export operations

To get the list of export operations, use the `operation list export/s3` command:

```
ydb -p quickstart operation list export/s3
```

The output format `operation list` is also set by the `--format` option.

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Exporting a database

Export all non-system database objects to the `export1` directory in the `mybucket` bucket using S3 authentication parameters from environment variables or the `~/.aws/credentials` file:

```
ydb -p quickstart export s3 \
  --s3-endpoint storage.yandexcloud.net --bucket mybucket \
  --destination-prefix export1
```

Exporting multiple directories

Export objects from the `dir1` and `dir2` directories of the database to the `export1` directory in the `mybucket` bucket, using explicitly specified S3 authentication parameters:

```
ydb -p quickstart export s3 \
  --s3-endpoint storage.yandexcloud.net --bucket mybucket \
  --access-key <access-key> --secret-key <secret-key> \
  --destination-prefix export1 --include dir1 --include dir2
```

Or using an alternative method:

```
ydb -p quickstart export s3 \
  --s3-endpoint storage.yandexcloud.net --bucket mybucket \
  --access-key <access-key> --secret-key <secret-key> \
  --item src=dir1,dst=export1/dir1 --item src=dir2,dst=export1/dir2
```

Export with encryption

Export the entire database with encryption:

- Using the `AES-128-GCM` encryption algorithm
- With generation of a random key by the `openssl` utility into the `~/my_secret_key` file
- With reading the generated key from the `~/my_secret_key` file
- To the path prefix `export1` in the S3 bucket `mybucket`
- Using S3 authentication parameters from environment variables or the `~/.aws/credentials` file

```
openssl rand -out ~/my_secret_key 16
ydb -p quickstart export s3 \
  --s3-endpoint storage.yandexcloud.net --bucket mybucket --destination-prefix export1 \
  --encryption-algorithm AES-128-GCM --encryption-key-file ~/my_secret_key
```

Exporting the `dir1` directory of the database with encryption:

- Using the `AES-256-GCM` encryption algorithm
- By generating a random key with the `openssl` utility into the `YDB_ENCRYPTION_KEY` environment variable
- By reading the generated key from the `YDB_ENCRYPTION_KEY` environment variable
- Into the path prefix `export1` in the S3 bucket `mybucket`
- Using S3 authentication parameters from environment variables or the `~/.aws/credentials` file

```
export YDB_ENCRYPTION_KEY=$(openssl rand -hex 32)
ydb -p quickstart export s3 \
  --root-path dir1 \
  --s3-endpoint storage.yandexcloud.net --bucket mybucket --destination-prefix export1 \
  --encryption-algorithm AES-256-GCM
```

Getting operation IDs

To get a list of export operation IDs in a format convenient for processing in bash scripts, you can use the jq utility:

```
ydb -p quickstart operation list export/s3 --format proto-json-base64 | jq -r ".operations[].id"
```

You will get output where each new line contains an operation ID, for example:

```
ydb://export/6?id=281474976789577&kind=s3
ydb://export/6?id=281474976789526&kind=s3
ydb://export/6?id=281474976788779&kind=s3
```

Using these IDs, you can, for example, run a loop to terminate all current operations:

```
ydb -p quickstart operation list export/s3 --format proto-json-base64 | jq -r ".operations[].id" | while read
line; do ydb -p quickstart operation forget $line;done
```

Importing data from an S3 compatible storage

The `import s3` command starts, on the server side, the process of importing data and schema objects details from an S3-compatible storage, in the format described in the File structure section:

```
ydb [connection options] import s3 [options]
```

where [connection options] are database connection options

As opposed to the `tools restore` command, the `import s3` command always creates objects in entirety, so none of the imported objects (directories or tables) should already exist.

If you need to load additional data into existing tables from S3, you can copy the S3 contents to the file system (for example, using S3cmd) and use the `tools restore` command.

> **Warning**
>
> The `tools restore` command loads data only into row tables. To append data to existing column tables, use external data sources. For more information, see Data import.

Command line parameters

`[options]`: Command parameters:

S3 parameters

To run the command to import data from an S3 storage, specify the S3 connection parameters. As data is imported by the YDB server asynchronously, the specified endpoint must be available so that a connection can be established from the server side.

`--source-prefix PREFIX`: Source prefix for export in the bucket.

Imported schema objects

`--destination-path PATH`: Destination folder for the objects being imported; defaults to the database root if not provided.

`--include PATH`: Schema objects to be included in the import. Directories are traversed recursively. You may specify this parameter multiple times to include several objects. If not specified, all objects in export are imported.

`--exclude STRING`: Template (PCRE) to exclude paths from import. Paths are relative to the `root-path`. You may specify this parameter multiple times for different templates.

Alternate syntax

There's an alternate syntax to specify the list of imported objects, supported for backward compatibility.

`--item STRING`: Description of the item to import. You can specify the `--item` parameter multiple times to import multiple items. If no `--item` or `--include` parameters are specified, all objects from the source prefix will be imported. `STRING` is specified in the `<property>=<value>,...` format with the following properties:

- `source`, `src`, or `s` is the key prefix in S3 that contains the imported directory or table.
- `destination`, `dst`, or `d` is the database path to host the imported directory or table. The destination of the path must not exist. All the directories along the path will be created if missing.

Some features may not be available using the alternate syntax (like encryption and listing).

Additional parameters

Parameter	Description
`--description STRING`	A text description of the operation saved in the operation history.
`--retries NUM`	The number of import retries to be made by the server. The default value is 10.
`--skip-checksum-validation`	Skip the validating imported objects' checksums step.
`--encryption-key-file PATH`	File path containing the encryption key (only for encrypted exports). The file is binary and must contain exactly the number of bytes matching the key length for the chosen encryption algorithm (16 bytes for `AES-128-GCM`, 32 bytes for `AES-256-GCM` and `ChaCha20-Poly1305`). The key can also be provided using the `YDB_ENCRYPTION_KEY` environment variable, in hexadecimal string representation.
`--list`	List objects in an existing export.
`--format STRING`	Result format. Possible values: • `pretty`: Human-readable format (default). • `proto-json-base64`: Protocol Buffers in JSON format, binary strings are Base64-encoded.

Importing

Import result

If successful, the `import s3` command prints summary information about the enqueued operation to import data from S3 in the format specified in the `--format` option. The import itself is performed by the server asynchronously. The summary shows the operation ID that you can use later to check the operation status and perform actions on it:

- In the default `pretty` mode, the operation ID is displayed in the id field with semigraphics formatting:

```
┌──────────────────────────────────────────────┬───────┬─────...
| id                                           | ready | stat...
├──────────────────────────────────────────────┼───────┼─────...
| ydb://import/8?id=281474976788395&kind=s3 | true  | SUCC...
├----------------------------------------------┴-------┴-----...
| Items:
...
```

- In the `proto-json-base64` mode, the operation ID is in the "id" attribute:

```
{"id":"ydb://export/8?id=281474976788395&kind=s3","ready":true, ... }
```

Import status

Data is imported in the background. To get information on import status, use the `operation get` command with the operation ID **enclosed in quotation marks** and passed as a command parameter. For example:

```
ydb -p quickstart operation get "ydb://import/8?id=281474976788395&kind=s3"
```

The `operation get` format is also set by the `--format` option.

Although the operation ID is in URL format, there is no guarantee that it is maintained in the future. It should only be interpreted as a string.

You can track the import by changes in the "progress" attribute:

- In the default `pretty` mode, successfully completed export operations are displayed as "Done" in the `progress` field with semigraphics formatting:

```
┌──────── ... ──┬─────────┬──────────┬────────────┬...
| id            | ready | status   | progress | ...
├──────────... ──┼─────────┼──────────┼────────────┼...
| ydb:/...      | true  | SUCCESS | Done     | ...
├------ ... ----┴-------┴---------┴----------┴ ...
...
```

- In the `proto-json-base64` mode, the completed export operation is indicated with the `PROGRESS_DONE` value of the `progress` attribute:

```
{"id":"ydb://...", ...,"progress":"PROGRESS_DONE",... }
```

Completing the import operation

When the import is complete, use `operation forget` to delete the import from the operation list:

```
ydb -p quickstart operation forget "ydb://import/8?id=281474976788395&kind=s3"
```

List of import operations

To get a list of import operations, run the `operation list import/s3` command:

```
ydb -p quickstart operation list import/s3
```

The `operation list` format is also set by the `--format` option.

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Importing to the database root

Importing to the database root the contents of the `export1` directory in the `mybucket` bucket using the S3 authentication parameters taken from the environment variables or the `~/.aws/credentials` file:

```
ydb -p quickstart import s3 \
  --s3-endpoint storage.yandexcloud.net --bucket mybucket \
  --source-prefix export1
```

Importing multiple directories

Importing items from the `dir1` and `dir2` directories of an export located in `export1` in the `mybucket` S3 bucket to the same-name database directories using explicitly specified S3 authentication parameters:

```
ydb -p quickstart import s3 \
  --s3-endpoint storage.yandexcloud.net --bucket mybucket \
  --access-key <access-key> --secret-key <secret-key> \
  --source-prefix export1
  --include dir1 --include dir2
```

List objects in existing encrypted export

Listing all object paths in existing encrypted export located in `export1` in the `mybucket` S3 bucket, using the secret key stored in the `~/my_secret_key` file.

```
ydb -p quickstart import s3 \
  --s3-endpoint storage.yandexcloud.net --bucket mybucket \
  --access-key <access-key> --secret-key <secret-key> \
  --source-prefix export1
  --encryption-key-file ~/my_secret_key
  --list
```

Importing encrypted export

Importing one table that was exported using the `dir/my_table` path to the `dir1/dir/my_table` path from an encrypted export located in `export1` in the `mybucket` S3 bucket, using the secret key stored in the `~/my_secret_key` file.

```
ydb -p quickstart import s3 \
  --s3-endpoint storage.yandexcloud.net --bucket mybucket \
  --access-key <access-key> --secret-key <secret-key> \
  --source-prefix export1 --destination-path dir1 \
  --include dir/my_table \
  --encryption-key-file ~/my_secret_key
```

Getting operation IDs

To get a list of import operation IDs in a bash-friendly format, use the jq utility:

```
ydb -p quickstart operation list import/s3 --format proto-json-base64 | jq -r ".operations[].id"
```

You'll get a result where each new line shows an operation's ID. For example:

```
ydb://import/8?id=281474976789577&kind=s3
ydb://import/8?id=281474976789526&kind=s3
ydb://import/8?id=281474976788779&kind=s3
```

You can use these IDs, for example, to run a loop to end all the current operations:

```
ydb -p quickstart operation list import/s3 --format proto-json-base64 | jq -r ".operations[].id" | while read
line; do ydb -p quickstart operation forget $line;done
```

Export to NFS

The `export nfs` command starts a server-side export process to the network file system (Network File System, NFS) of the YDB cluster hosts, exporting data and schema object information in the format described in the File structure article:

```
ydb [connection options] export nfs [options]
```

where [connection options] are database connection options

Warning

Export is available only for objects of the following types:

- directory.
- row table.
- secondary index.
- vector index.
- full-text index.
- local Bloom skip index.
- topic (schema only).
- view.
- asynchronous replication.
- transfer.
- external data source.
- external table.

Warning

Currently, this command does not process column tables. To export column tables, use the `export s3` command.

Command line parameters

`[options]` — command parameters:

NFS parameters

The NFS export command requires specifying a mounted directory (or subdirectory) common to all objects involved in the export. Since the export is performed asynchronously on all YDB hosts, the specified directory must exist on each YDB host and be mounted in NFS.

`--fs-path PATH` : path to the mounted directory (or subdirectory).

List of exported objects

`--root-path PATH` : Root directory for exported objects. If not specified, the root directory of the database is used.

`--include PATH` : Data schema objects to include in the export. Directories are traversed recursively. Paths are specified relative to `root-path` . This parameter can be specified multiple times to include multiple objects. If not specified, all non-system objects in `root-path` are exported.

`--exclude STRING` : Pattern (PCRE) to exclude paths from the export. Paths are specified relative to `root-path` . This parameter can be specified multiple times for different patterns.

Alternative method

An alternative way to specify the list of objects is supported:

`--item STRING` : Description of the export object. The `--item` parameter can be specified multiple times if you need to export several objects. `STRING` is specified in the `<property>=<value>,...` format, with the following required properties:

- `source` , `src` , or `s` — path to the exported directory or table; `.` points to the root directory of the database. When specifying a directory, all non-system objects in it are exported, as well as all non-system subdirectories recursively.
- `destination` , `dst` , or `d` — path in NFS (relative to `--fs-path`).

`--exclude STRING` : Pattern (PCRE) to exclude paths from export. This parameter can be specified multiple times for different patterns.

Warning

Exports made using alternative syntax will not contain a list of objects in the backup, so some features may be unavailable for them (in particular, encrypted backups), and import is only possible using the corresponding alternative import syntax.

Additional parameters

Parameter	Description
`--description STRING`	Text description of the operation, saved in the operation history.
`--retries NUM`	Number of retry attempts for export that the server will make. Default value: `10` .

`--compression STRING`	Compress exported data. With the default compression level for the Zstandard algorithm, data can be compressed by 5-10 times. Data compression uses CPU resources and may affect the speed of other database operations. Allowed values: • `zstd` — compression using the Zstandard algorithm with the default compression level (`3`); • `zstd-N` — compression using the Zstandard algorithm, `N` — compression level (`1` — `22`).
`--encryption-algorithm ALGORITHM`	Encrypt exported data using the specified algorithm. Supported values: `AES-128-GCM` , `AES-256-GCM` , `ChaCha20-Poly1305` .
`--encryption-key-file PATH`	Path to the file containing the encryption key (only for encrypted exports). This file is binary and must contain the exact number of bytes corresponding to the key length in the selected encryption algorithm (16 bytes for `AES-128-GCM` , 32 bytes for `AES-256-GCM` and `ChaCha20-Poly1305`). The key can also be passed via the `YDB_ENCRYPTION_KEY` environment variable, in hexadecimal string representation.
`--format STRING`	Output format. Allowed values: • `pretty` — human-readable format (default); • `proto-json-base64` — Protocol Buffers in JSON format, binary strings encoded in Base64.

Running the export

Server export operation flow

1. A server asynchronous export operation is created.
2. In the root directory of the database, a service directory `export-{id}` is created, where `{id}` is the numeric operation ID.
3. A consistent copy of the tables is created in this directory using the `CopyTables` mechanism.
4. The data of each table is written from the copy to the storage in the export file structure format, with parallel writing from different cluster nodes.
5. After successful completion, the service directory `export-{id}` and the table copies are deleted.

Launch result

Upon successful execution, the `export nfs` command outputs summary information about the queued NFS export operation, in the format specified by the `--format` option. The actual export is performed asynchronously by the server. The summary information includes the operation ID, which can be used later to check the status and perform actions on the operation:

- In the `pretty` output mode (default), the operation ID is shown in the id field highlighted with pseudographics:

```
┌──────────────────────────────────────────┬───────┬─────...
| id                                       | ready | stat...
├──────────────────────────────────────────┼───────┼─────...
| ydb://export/6?id=281474976788395&kind=fs | true  | SUCC...
├------------------------------------------┴-------┴-----...
| Include index data: false
| Items:
...
```

- In the `proto-json-base64` output mode, the identifier is in the "id" attribute:

```
{"id":"ydb://export/6?id=281474976788395&kind=fs","ready":true, ... }
```

Export status

Data export runs in the background. You can get information about the status and progress of the export by calling the `operation get` command, which must be passed the **quoted** operation ID, for example:

```
ydb -p quickstart operation get "ydb://export/6?id=281474976788395&kind=fs"
```

The output format `operation get` is also set by the `--format` option.

Although the operation ID is in URL format, it is not guaranteed to be preserved in the future. It should be interpreted only as a string.

Completion of the export is tracked by changes in the "progress" attribute:

- In the `pretty` output mode (default), a successfully completed operation is reflected by the value "Done" in the `progress` field highlighted with pseudographics:

```
┌──────  ...  ──┬───────┬──────────┬────────────┬...
| id            | ready | status   | progress   | ...
├──────...  ──┼───────┼──────────┼────────────┼...
| ydb://...     | true  | SUCCESS | Done       | ...
├-----  ...  --┴-------┴---------┴------------┴ ...
...
```

- In the `proto-json-base64` output mode, a completed operation is reflected by the value `PROGRESS_DONE` of the `progress` attribute:

```
{"id":"ydb://...", ...,"progress":"PROGRESS_DONE",... }
```

Completing the export operation

After completing the export, use the `operation forget` command to mark the export as completed (removed from the list of operations):

```
ydb -p quickstart operation forget "ydb://export/6?id=281474976788395&kind=fs"
```

List of export operations

To get the list of export operations, use the `operation list export/nfs` command:

```
ydb -p quickstart operation list export/nfs
```

The output format `operation list` is also set by the `--format` option.

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Exporting a database

Export all non-system database objects to the `/mnt/nfs/backups/export1` directory on the file system:

```
ydb -p quickstart export nfs \
  --fs-path /mnt/nfs/backups/export1
```

Exporting multiple directories

Export objects from the `dir1` and `dir2` directories of the database to the `/mnt/nfs/backups/export1` directory on the file system:

```
ydb -p quickstart export nfs \
  --fs-path /mnt/nfs/backups/export1 \
  --include dir1 --include dir2
```

Or using an alternative method:

```
ydb -p quickstart export nfs \
  --fs-path /mnt/nfs/backups \
  --item src=dir1,dst=export1/dir1 --item src=dir2,dst=export1/dir2
```

Export with encryption

Export the entire database with encryption:

- Using the `AES-128-GCM` encryption algorithm
- With generation of a random key by the `openssl` utility into the `~/my_secret_key` file
- With reading the generated key from the `~/my_secret_key` file
- To the `/mnt/nfs/backups/export1` directory on the file system

```
openssl rand -out ~/my_secret_key 16
ydb -p quickstart export nfs \
  --fs-path /mnt/nfs/backups/export1 \
  --encryption-algorithm AES-128-GCM --encryption-key-file ~/my_secret_key
```

Exporting the `dir1` directory of the database with encryption:

- Using the `AES-256-GCM` encryption algorithm
- By generating a random key with the `openssl` utility into the `YDB_ENCRYPTION_KEY` environment variable
- By reading the generated key from the `YDB_ENCRYPTION_KEY` environment variable
- To the `/mnt/nfs/backups/export1` directory on the file system

```
export YDB_ENCRYPTION_KEY=$(openssl rand -hex 32)
ydb -p quickstart export nfs \
  --root-path dir1 \
  --fs-path /mnt/nfs/backups/export1 \
  --encryption-algorithm AES-256-GCM
```

Getting operation IDs

To get a list of export operation IDs in a format convenient for processing in bash scripts, you can use the jq utility:

```
ydb -p quickstart operation list export/nfs --format proto-json-base64 | jq -r ".operations[].id"
```

You will get output where each new line contains an operation ID, for example:

```
ydb://export/6?id=281474976789577&kind=fs
ydb://export/6?id=281474976789526&kind=fs
ydb://export/6?id=281474976788779&kind=fs
```

Using these IDs, you can, for example, run a loop to terminate all current operations:

```
ydb -p quickstart operation list export/nfs --format proto-json-base64 | jq -r ".operations[].id" | while rea
d line; do ydb -p quickstart operation forget $line;done
```

Import from NFS

The `import nfs` command starts a server-side import process from the network file system (Network File System, NFS) of the YDB cluster hosts, importing data and schema object information in the format described in the File structure article:

```
ydb [connection options] import nfs [options]
```

where [connection options] are database connection options

> **Warning**
>
> Currently, this command does not restore column table data. To import column tables, use the `import s3` command with a backup created by `export s3`.

Unlike the `tools restore` command, the `import nfs` command always creates objects entirely, so for it to succeed, none of the imported objects (neither directories nor tables) must exist.

If you need to load additional data into existing tables, use the `tools restore` command directly on the mounted NFS directory.

Command line parameters

`[options]` — command parameters:

NFS parameters

The import from NFS command requires specifying a mounted directory (or subdirectory) common to all objects involved in the import. Since the import is performed asynchronously on all YDB hosts, the specified directory must be present on each YDB host and mounted in NFS.

`--fs-path PATH`: path to the mounted directory (or subdirectory).

Imported database schema objects

`--destination-path PATH`: Target directory for imported objects; the default value is the database root.

`--include PATH`: Data schema objects to include in the import. Directories are traversed recursively. To include multiple objects, the parameter can be specified multiple times. If not specified, all exported objects are imported.

`--exclude STRING`: Pattern (PCRE) to exclude paths from the import. This parameter can be specified multiple times for different patterns.

Alternative method

For backward compatibility, an alternative way to specify the list of objects is supported:

`--item STRING`: Description of the object to load. The `--item` parameter can be specified multiple times if you need to load several objects. If the `--item` or `--include` parameters are not specified, all objects present in the specified dump will be loaded. `STRING` is specified in the `<property>=<value>,...` format with the following required properties:

- `source`, `src`, or `s` — path in NFS (relative to `fs-path`) with the imported directory or table.
- `destination`, `dst`, or `d` — the path in the database for placing the imported directory or table. The final path element must not exist. All directories on the path will be created if they do not exist.

Some features may be unavailable when using alternative syntax (in particular, encrypted backups or listing of export objects).

Additional parameters

Parameter	Description
`--description STRING`	Text description of the operation, saved in the operation history.
`--retries NUM`	Number of retry attempts the server will make. Default value: `10`.
`--skip-checksum-validation`	Skip the validation stage of checksums of imported objects.
`--encryption-key-file PATH`	Path to the file containing the encryption key (only for encrypted exports). This file is binary and must contain the exact number of bytes corresponding to the key length in the selected encryption algorithm (16 bytes for `AES-128-GCM`, 32 bytes for `AES-256-GCM` and `ChaCha20-Poly1305`). The key can also be passed via the `YDB_ENCRYPTION_KEY` environment variable, in hexadecimal string representation.
`--format STRING`	Result output format. Valid values: • `pretty` — human-readable format (default); • `proto-json-base64` — Protocol Buffers in JSON format, binary strings encoded in Base64.

Running the import

Server import operation flow

1. A server asynchronous import operation is created.
2. The server reads object metadata from files (`scheme.pb`, `metadata.json`, etc.) from the storage.
3. For each object, a new table is created in the database. Target paths **must not exist** — import cannot overwrite existing tables.
4. Data is loaded from files in parallel on all cluster nodes.

Launch result

Upon successful execution, the `import nfs` command outputs summary information about the queued import from NFS operation, in the format specified by the `--format` option. The actual import is performed asynchronously by the server. The summary information includes the operation ID, which can later be used to check the status and perform actions on the operation:

- In the `pretty` output mode (default), the operation ID is shown in the id field highlighted with pseudographics:

```
┌──────────────────────────────────────────────┬───────┬─────...
| id                                           | ready | stat...
├──────────────────────────────────────────────┼───────┼─────...
| ydb://import/8?id=281474976788395&kind=fs | true  | SUCC...
├----------------------------------------------┴-------┴-----...
| Items:
...
```

- In the `proto-json-base64` output mode, the identifier is in the "id" attribute:

```
{"id":"ydb://import/8?id=281474976788395&kind=fs","ready":true, ... }
```

Import status

Data loading is performed in the background. You can get information about the status and progress of the loading by calling the `operation get` command, whose parameter must be the **quoted** operation identifier, for example:

```
ydb -p quickstart operation get "ydb://import/8?id=281474976788395&kind=fs"
```

The output format `operation get` is also set by the `--format` option.

Although the operation ID is in URL format, it is not guaranteed to be preserved in the future. It should be interpreted only as a string.

The completion of the upload is tracked by the change of the "progress" attribute:

- In the `pretty` output mode (default), a successfully completed operation is reflected by the value "Done" in the `progress` field highlighted with pseudographics:

```
┌──────  ... ──┬─────────┬──────────┬─────────────┬...
| id           | ready | status   | progress | ...
├──────... ──┼─────────┼──────────┼─────────────┼...
| ydb://...    | true  | SUCCESS | Done      | ...
├-----  ... --┴-------┴---------┴----------┴ ...
...
```

- In the `proto-json-base64` output mode, a completed operation is reflected by the value `PROGRESS_DONE` of the `progress` attribute:

```
{"id":"ydb://...", ...,"progress":"PROGRESS_DONE",... }
```

Completing an import operation

After completing the import, use the `operation forget` command to remove the import from the list of operations:

```
ydb -p quickstart operation forget "ydb://import/8?id=281474976788395&kind=fs"
```

List of import operations

To get a list of import operations, use the `operation list import/nfs` command:

```
ydb -p quickstart operation list import/nfs
```

The output format `operation list` is also set by the `--format` option.

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Importing to the database root

Importing the contents of the `/mnt/nfs/backups/export1` directory on the file system into the database root:

```
ydb -p quickstart import nfs \
  --fs-path /mnt/nfs/backups/export1
```

Importing multiple directories

Importing objects from the `dir1` and `dir2` directories of the export located in `/mnt/nfs/backups/export1` on the file system into the database directories with the same names:

```
ydb -p quickstart import nfs \
  --fs-path /mnt/nfs/backups/export1 \
  --include dir1 --include dir2
```

Importing an encrypted export

Importing a single table that was exported along the `dir/my_table` path into the `dir1/dir/my_table` path from an encrypted export located in `/mnt/nfs/backups/export1` on the file system, using a secret key from the `~/my_secret_key` file.

```
ydb -p quickstart import nfs \
  --fs-path /mnt/nfs/backups/export1 --destination-path dir1 \
  --include dir/my_table \
  --encryption-key-file ~/my_secret_key
```

Getting operation IDs

To get a list of import operation IDs in a format convenient for processing in bash scripts, you can use the jq utility:

```
ydb -p quickstart operation list import/nfs --format proto-json-base64 | jq -r ".operations[].id"
```

You will get output where each new line contains an operation ID, for example:

```
ydb://import/8?id=281474976789577&kind=fs
ydb://import/8?id=281474976789526&kind=fs
ydb://import/8?id=281474976788779&kind=fs
```

Using these IDs, you can, for example, run a loop to terminate all current operations:

```
ydb -p quickstart operation list import/nfs --format proto-json-base64 | jq -r ".operations[].id" | while rea
d line; do ydb -p quickstart operation forget $line;done
```

Importing data from a file to an existing table

With the `import file` command, you can import data from CSV or TSV files to an existing table.

Data from an imported file is read in batches whose size is set in the `--batch-bytes` option. An independent query is used to write each batch to the database. The queries are executed asynchronously. When the number of executed queries reaches `--max-in-flight`, reading from the file pauses. You can import data from multiple files using a single command. In this case, data from the files will be read asynchronously.

The command implements the `BulkUpsert` method, which ensures high efficiency of multi-row bulk upserts with no atomicity guarantees. The upsert process is split into multiple independent parallel transactions, each covering a single partition. When completed successfully, it guarantees that all data is upserted.

If the table already includes data, it's replaced by imported data on primary key match.

The imported file must be in the UTF-8 encoding. Line feeds aren't supported in the data field.

Note

If the table doesn't exist yet, you can use the ydb tools infer csv command to generate the `CREATE TABLE` statement based on an existing CSV file.

You can also try to import into a non-existent table. In that case, the command will suggest running ydb tools infer csv with the correct options.

General format of the command:

```
ydb [connection options] import file csv|json|parquet|tsv [options] <input files...>
```

where [connection options] are database connection options

`<input files>`: Paths to local file system files you want to import.

Subcommand options

Required options

- `-p, --path STRING`: A path to the table in the database.

Additional options

- `--timeout VAL`: Time within which the operation should be completed on the server. Default: `300s`.
- `--skip-rows NUM`: A number of rows from the beginning of the file that will be skipped at import. The default value is `0`.
- `--header`: Use this option if the first row (excluding the rows skipped by `--skip-rows`) includes names of data columns to be mapped to table columns. If the header row is missing, the data is mapped according to the order in the table schema.
- `--delimiter STRING`: The data column delimiter character. You can't use the tabulation character as a delimiter in this option. For tab-delimited import, use the `import file tsv` subcommand. Default value: `,`.
- `--null-value STRING`: The value to be imported as `NULL`. Default value: `""`.
- `--batch-bytes VAL`: Split the imported file into batches of specified sizes. If a row fails to fit into a batch completely, it's discarded and added to the next batch. Whatever the batch size is, the batch must include at least one row. Default value: `1 MiB`.
- `--max-in-flight VAL`: The number of data batches imported in parallel. You can increase this option value to import large files faster. The default value is `100`.
- `--threads VAL`: Maximum number of threads used to import data. Default value: Number of logical processors.
- `--columns`: List of data columns in the file delimited by a `comma` (for `csv` format) or by a tab character (for `tsv` format). If you use the `--header` option, the column names in it will be replaced by column names from the list. If the number of columns in the list mismatches the number of data columns, you will get an error.
- `--newline-delimited`: This flag guarantees that there will be no line breaks in records. If this flag is set, and the data is loaded from a file, then different upload streams will process different parts of the source file. This way you can distribute the workload across all partitions, ensuring the maximum performance when uploading sorted datasets to partitioned tables.

Examples

Note

The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Before performing the examples, create a table named `series`.

Import file

The file includes data without any additional information. The `,` character is used as a delimiter.

```
1,IT Crowd,The IT Crowd is a British sitcom.,13182
2,Silicon Valley,Silicon Valley is an American comedy television series.,16166
```

Note

The `release_date` column in the `series` table has the Date type, so the release date in the imported file has a numeric format. To import values in the timestamp format, use string-type table columns for them. Alternatively, you can import them to a temporary table and convert them to a relevant type.

To import such a file, use the command:

```
ydb import file csv -p series series.csv
```

The following data will be imported:

```
┌──────────────┬───────────┬──────────────────────────────────────────────────────────┬──────────────┐
| release_date | series_id | series_info                                              | title        |
├──────────────┼───────────┼──────────────────────────────────────────────────────────┼──────────────┤
| "2006-02-03" | 1         | "The IT Crowd is a British sitcom."                      | "IT Crowd"   |
├──────────────┼───────────┼──────────────────────────────────────────────────────────┼──────────────┤
| "2014-04-06" | 2         | "Silicon Valley is an American comedy television series." | "Silicon Valley" |
└──────────────┴───────────┴──────────────────────────────────────────────────────────┴──────────────┘
```

Importing multiple files

The following files include CSV data without additional information:

- series1.csv:

  ```
  1,IT Crowd,The IT Crowd is a British sitcom.,131822
  ```

- series2.csv:

  ```
  2,Silicon Valley,Silicon Valley is an American comedy television series., 16166
  ```

To import such files, run the command:

```
ydb import file csv -p series series1.csv series2.csv
```

Import file with the `|` delimiter

The file includes data without any additional information. The `|` character is used as a delimiter.

```
1|IT Crowd|The IT Crowd is a British sitcom.|13182
2|Silicon Valley|Silicon Valley is an American comedy television series.|16166
```

To import such a file, use `|` in the `--delimiter` option:

```
ydb import file csv -p series --delimiter "|" series.csv
```

Skip rows and read column headers

The file includes additional information in the first and second row, as well as column headers in the third row. The order of data in the file rows mismatches the order of columns in the table:

```
#The file contains data about the series.
#
series_id,title,release_date,series_info
1,IT Crowd,13182,The IT Crowd is a British sitcom.
2,Silicon Valley,16166,Silicon Valley is an American comedy television series.
```

To skip comments in the first and second rows, use `--skip-rows 2`. To process the third row as headers and map the file data to table columns, use the `--header` option:

```
ydb import file csv -p series --skip-rows 2 --header series.csv
```

Replace values to `NULL`

The file includes the `\N` sequence often used for `NULL`, as well as empty strings.

```
1,IT Crowd,The IT Crowd is a British sitcom.,13182
2,Silicon Valley,"",\N
3,Lost,,\N
```

Use `--null-value "\N"` so that `\N` is interpreted as `NULL`:

```
ydb import file csv -p series --null-value "\N" series.csv
```

The following data will be imported:

```
┌──────────────┬───────────┬──────────────────────────────────┬──────────────────┐
| release_date | series_id | series_info                      | title            |
├──────────────┼───────────┼──────────────────────────────────┼──────────────────┤
| "2006-02-03" | 1         | "The IT Crowd is a British sitcom." | "IT Crowd"       |
├──────────────┼───────────┼──────────────────────────────────┼──────────────────┤
| null         | 2         | ""                               | "Silicon Valley" |
├──────────────┼───────────┼──────────────────────────────────┼──────────────────┤
| null         | 3         | ""                               | "Lost"           |
└──────────────┴───────────┴──────────────────────────────────┴──────────────────┘
```

Backup and recovery

YDB is initially designed for data safety in case of hardware failures: redundancy options are available for different numbers of availability zones, racks, hosts, disks, and other components (see cluster operating modes). This reduces the risk of data loss due to hardware failures.

However, data can be lost or corrupted **logically**: errors or malicious actions can lead to mass deletion/corruption of data by operations legitimate for the DBMS. In such cases, cluster fault tolerance does not replace a **separate copy** of data outside the cluster.

Backup is used to protect against such scenarios and allows restoring data from a backup. It is recommended to store copies on a separate medium or in cloud object storage (for example, via export to files or export to S3).

YDB provides several solutions for performing backup and recovery. For conceptual information and comparison of backup methods, see backup concepts.

- Backup to files and recovery using the YDB CLI.
- Backup to S3-compatible storage and recovery using the YDB CLI.
- Backup of system tablets to the local file system of cluster hosts.

YDB CLI

Files

The following commands are used for backup to files:

- `ydb admin cluster dump` — for backing up cluster metadata
- `ydb admin database dump` — for backing up the database
- `ydb tools dump` — for backing up individual schema objects or directories

Learn more about these commands in Exporting data to the file system.

The following commands are used for restoration from a file backup:

- `ydb admin cluster restore` — for restoring cluster metadata from a backup
- `ydb admin database restore` — for restoring the database from a backup
- `ydb tools restore` — for restoring individual schema objects or directories from a backup

Learn more about these commands in Importing data from the file system.

S3-compatible storage

To perform backup to an S3-compatible storage (for example, AWS S3), the `ydb export s3` command is used. Follow the link to the YDB CLI reference for information about this command.

To perform restoration from a backup created in an S3-compatible storage, the `ydb import s3` command is used. Follow the link to the YDB CLI reference for information about this command.

NFS

To perform backup to NFS on hosts where YDB is running, the `ydb export nfs` command is used. Follow the link to the YDB CLI reference for information about this command.

To perform restoration from a backup created in NFS on hosts where YDB is running, the `ydb import nfs` command is used. Follow the link to the YDB CLI reference for information about this command.

For more details on configuring NFS for backup and recovery, see the recipe Backup and recovery via NFS.

> **Note**
>
> The speed of backup and restore operations to/from S3-compatible storage or NFS is tuned to minimize the impact on user load. To control the operation speed, configure limits for the corresponding queue of the resource broker.

> **Note**
>
> When performing an export, a directory named `export_*` is created in the root directory of the database, where `*` is the numeric part of the export identifier. This directory contains tables that hold a consistent snapshot of the exported data at the time the export started. After the backup operation completes successfully, the `export_*` directory along with its contents is deleted.

Backup collections

Backup collections provide incremental backup and point-in-time recovery for production workloads. For conceptual information and architecture details, see Backup collections.

Backup collections are recommended for production environments with a regular backup schedule and large datasets where incremental changes are significantly smaller than the total volume. For simpler scenarios (one-time migrations, development environments, small databases), consider using export/import or dump/restore.

For step-by-step instructions on configuring and using backup collections, see:

- Backup collections — architecture, concepts, and limitations
- Recipes for backup collections — typical scenarios and examples

Backup of system tablets

The system tablet backup mechanism provides incremental copying of cluster metadata to the local file system of the cluster hosts.

For conceptual information and how it works, see Backup concepts.

For step-by-step instructions on enabling and restoring, see Recipes for system tablet backup.

Commands for topics

Using YDB CLI commands, you can perform the following operations:

- Creating a topic.
- Updating a topic.
- Deleting a topic.
- Adding a topic consumer.
- Deleting a topic consumer.
- Saving a consumer offset.
- Reading messages from a topic.
- Writing messages to a topic.

Creating a topic

You can use the `topic create` subcommand to create a new topic.

General format of the command:

```
ydb [global options...] topic create [options...] <topic-path>
```

- `global options` : Global parameters.
- `options` : Parameters of the subcommand.
- `topic-path` : Topic path.

View the description of the create topic command:

```
ydb topic create --help
```

Parameters of the subcommand

Name	Description
`--partitions-count`	The number of topic partitions. The default value is `1`.
`--retention-period`	Data retention time in a topic. A positive number followed by a unit of time. The following units are supported: • `s` – seconds; • `m` – minutes; • `h` – hours; • `d` – days. The default value is `24h`.
`--partition-write-speed-kbps`	The maximum write speed to a partition, specified in KB/s. The default value is `1024`.
`--retention-storage-mb`	The maximum storage size, specified in MB. When the limit is reached, the oldest data will be deleted. The consumed space may exceed the set value when autopartitioning is enabled. The default value is `0` (no limit).
`--auto-partitioning-strategy`	Auto-partitioning modes. Possible values: • `up` — the number of partitions can increase under high load, but cannot decrease; • `paused` — automatic scaling of the number of partitions is paused; • `disabled` — automatic scaling of the number of partitions is disabled. The default value is `disabled`.
`--supported-codecs`	Supported data compression methods. Set with a comma. The default value is `raw`. Possible values: • `RAW`: No compression. • `ZSTD`: zstd compression. • `GZIP`: gzip compression. • `LZOP`: lzop compression.
`--metering-mode`	The topic pricing method for a serverless database. Possible values: • `request-units`: Based on actual usage. • `reserved-capacity`: Based on dedicated resources.

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Create a topic with 2 partitions, `RAW` and `GZIP` compression methods, message retention time of 2 hours, and the `my-topic` path:

```
ydb -p quickstart topic create \
  --partitions-count 2 \
  --supported-codecs raw,gzip \
  --retention-period 2h \
  my-topic
```

View parameters of the created topic:

```
ydb -p quickstart scheme describe my-topic
```

Result:

```
RetentionPeriod: 2h
PartitionsCount: 2
SupportedCodecs: RAW, GZIP
```

Updating a topic

You can use the `topic alter` subcommand to update a previously created topic.

General format of the command:

```
ydb [global options...] topic alter [options...] <topic-path>
```

- `global options` : Global parameters.
- `options` : Parameters of the subcommand.
- `topic-path` : Topic path.

View the description of the update topic command:

```
ydb topic alter --help
```

Parameters of the subcommand

The command changes the values of parameters specified in the command line. The other parameter values remain unchanged.

Name	Description
`--partitions-count`	The number of topic partitions. You can only increase the number of partitions.
`--retention-period`	Data retention time in a topic. A positive number followed by a unit of time. The following units are supported: • `s` – seconds; • `m` – minutes; • `h` – hours; • `d` – days.
`--partition-write-speed-kbps`	The maximum write speed to a partition, specified in KB/s. The default value is `1024`.
`--retention-storage-mb`	The maximum storage size, specified in MB. When the limit is reached, the oldest data will be deleted. The consumed space may exceed the set value when autopartitioning is enabled. The default value is `0` (no limit).
`--auto-partitioning-strategy`	Auto-partitioning modes. Possible values: • `up` — the number of partitions can increase under high load, but cannot decrease; • `paused` — automatic scaling of the number of partitions is paused.
`--supported-codecs`	Supported data compression methods. Possible values: • `RAW`: No compression. • `ZSTD`: zstd compression. • `GZIP`: gzip compression. • `LZOP`: lzop compression.
`--metering-mode`	The topic pricing method for a serverless database. Possible values: • `request-units`: Based on actual usage. • `reserved-capacity`: Based on dedicated resources.

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Add a partition and the `lzop` compression method to the previously created topic:

```
ydb -p quickstart topic alter \
  --partitions-count 3 \
  --supported-codecs raw,gzip,lzop \
  my-topic
```

Make sure that the topic parameters have been updated:

```
ydb -p quickstart scheme describe my-topic
```

Result:

```
RetentionPeriod: 2h
PartitionsCount: 3
SupportedCodecs: RAW, GZIP, LZOP
```

Deleting a topic

You can use the `topic drop` subcommand to delete a previously created topic.

> **Note**
>
> Deleting a topic also deletes all the consumers added for it.

General format of the command:

```
ydb [global options...] topic drop <topic-path>
```

- `global options`: Global parameters.
- `topic-path`: Topic path.

View the description of the delete topic command:

```
ydb topic drop --help
```

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Delete the previously created topic:

```
ydb -p quickstart topic drop my-topic
```

Adding a topic consumer

You can use the `topic consumer add` command to add a consumer for a previously created topic.

General format of the command:

```
ydb [global options...] topic consumer add [options...] <topic-path>
```

- `global options` : Global parameters.
- `options` : Parameters of the subcommand.
- `topic-path` : Topic path.

View the description of the add consumer command:

```
ydb topic consumer add --help
```

Parameters of the subcommand

Name	Description
`--consumer VAL`	Name of the consumer to be added.
`--starting-message-timestamp VAL`	Time in UNIX timestamp format. Consumption starts as soon as the first message is received after the specified time. If the time is not specified, consumption will start from the oldest message in the topic.
`--supported-codecs`	Supported data compression methods. The default value is `raw`. Possible values: • `RAW` : No compression. • `ZSTD` : zstd compression. • `GZIP` : gzip compression. • `LZOP` : lzop compression.

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Create a consumer with the `my-consumer` name for the previously created `my-topic` topic. Consumption will start as soon as the first message is received after August 15, 2022 13:00:00 GMT:

```
ydb -p quickstart topic consumer add \
  --consumer my-consumer \
  --starting-message-timestamp 1660568400 \
  my-topic
```

Make sure the consumer was created:

```
ydb -p quickstart scheme describe my-topic
```

Result:

```
RetentionPeriod: 2h
PartitionsCount: 2
SupportedCodecs: RAW, GZIP

Consumers:
┌──────────────┬─────────────────┬──────────────────────────────┬─────────────┐
| ConsumerName | SupportedCodecs | ReadFrom                     | Important |
├──────────────┼─────────────────┼──────────────────────────────┼─────────────┤
| my-consumer  | RAW, GZIP       | Mon, 15 Aug 2022 16:00:00 MSK | 0         |
└──────────────┴─────────────────┴──────────────────────────────┴─────────────┘
```

Deleting a topic consumer

You can use the `topic consumer drop` command to delete a previously added consumer.

General format of the command:

```
ydb [global options...] topic consumer drop <topic-path>
```

- `global options`: Global parameters.
- `topic-path`: Topic path.

View the description of the delete consumer command:

```
ydb topic consumer drop --help
```

Parameters of the subcommand

Name	Description
`--consumer VAL`	Name of the consumer to be deleted.

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Delete the previously created consumer with the `my-consumer` name for the `my-topic` topic:

```
ydb -p quickstart topic consumer drop \
  --consumer my-consumer \
  my-topic
```

Saving a consumer offset

Each topic consumer has a consumer offset.

You can use the `topic consumer offset commit` command to save the consumer offset for the consumer that you added.

General format of the command:

```
ydb [global options...] topic consumer offset commit [options...] <topic-path>
```

- `global options` : Global parameters.
- `options` : Parameters of the subcommand.
- `topic-path` : Topic path.

Viewing the command description:

```
ydb topic consumer offset commit --help
```

Parameters of the subcommand

Name	Description
`--consumer <value>`	Consumer name.
`--partition <value>`	Partition number.
`--offset <value>`	Offset value that you want to set.

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

For `my-consumer`, set the offset of 123456789 in `my-topic` and partition `1`:

```
ydb -p db1 topic consumer offset commit \
  --consumer my-consumer \
  --partition 1 \
  --offset 123456789 \
  my-topic
```

Reading messages from a topic

The `topic read` command reads messages from a topic and outputs them to a file or the command-line terminal:

```
ydb [connection options] topic read <topic-path> --consumer STR \
  [--format STR] [--wait] [--limit INT] \
  [--transform STR] [--file STR] [--commit BOOL] \
  [additional parameters...]
```

where [connection options] are database connection options

Three command modes are supported:

1. **Single message**. No more than one message is read from a topic.
2. **Batch mode**. Messages are read from a topic until it runs out of messages for processing or their number exceeds the limit that must be set.
3. **Streaming mode**. Messages are read from a topic as they appear while waiting for new messages to arrive until you terminate the command with `Ctrl+C` or the number of messages exceeds the limit that is set optionally.

Parameters

Required parameters

`<topic-path>`: Topic path

Basic optional parameters

`-c VAL`, `--consumer VAL`: Topic consumer name.

- If not set, then you need to specify partitions through --partition-ids to read without consumer
- Message consumption starts from the current offset for this consumer (if the `--timestamp` parameter is not specified).
  If consumer name is not specified, message consumption will start from the first message in partition.

`--format STR`: Output format.

- Specifies how to format messages at the output. Some formats don't support streaming mode.
- List of supported formats:

Name	Description	Is streaming mode supported?
`single-message` (default)	The contents of no more than one message are output without formatting.	-
`pretty`	Output to a pseudo-graphic table with columns containing message metadata. The message itself is output to the `body` column.	No
`newline-delimited`	Messages are output with a delimiter (`0x0A` newline character) added after each message.	Yes
`concatenated`	Messages are output one after another with no delimiter added.	Yes

`--wait` (`-w`): Waiting for new messages to arrive.

- Enables waiting for the first message to appear in a topic. If not set and the topic has no messages to handle, the command is terminated once started. If the flag is set, the started read message command waits for the first message to arrive to be processed.
- Enables streaming selection mode for the formats that support it, or else batch mode is used.

`--limit INT`: The maximum number of messages that can be consumed from a topic.

- The default and acceptable values depend on the selected output format:

Does the format support streaming selection mode?	Default limit value	Acceptable values
No	10	1-500
Yes	0 (no limit)	0-500

`--transform VAL`: Method for transforming messages.

- Defaults to `none`.
- Possible values:
  `base64`: A message is transformed into Base64
  `none`: The contents of a message are output byte by byte without transforming them.

`--file VAL` (`-f VAL`): Write the messages read to the specified file. If not set, messages are output to `stdout`.

`--commit BOOL`: Commit message reads. Default value - `false`.

- Possible values: `true` or `false`.
- If `true`, a consumer's current offset is shifted as topic messages are consumed.
- If the value is set to `false`, messages will be read, but the reading progress won't be saved, and upon restart, the messages will be read again. This functionality is useful for debugging: allowing messages to be read without affecting the production system (without offset commit).

Other optional parameters

Name	Description
`--idle-timeout VAL`	Timeout for deciding if a topic is empty, meaning that it contains no messages for processing. The time is counted from the point when a connection is established once the command is run or when the last message is received. If no new messages arrive from the server during the specified timeout, the topic is considered to be empty. Defaults to `1s` (1 second).
`--timestamp VAL`	Message consumption starts from the point in time specified in UNIX timestamp format. If not set, messages are consumed starting from the consumer's current offset in the topic. If set, consumption starts from the first message received after the specified time.
`--metadata-fields VAL`	List of message attributes whose values should be output in columns with metadata in `pretty` format. If not set, columns with all attributes are output. Possible values: • `write_time`: The time a message is written to the server in UNIX timestamp format. • `meta`: Message metadata. • `create_time`: The time a message is created by the source in UNIX timestamp format. • `seq_no`: Message sequence number. • `offset`: Message sequence number within a partition. • `message_group_id`: Message group ID. • `body`: Message body.
`--partition-ids VAL`	Comma-separated list of partition identifiers to read from. If not specified, messages are read from all partitions.

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

In all the examples below, a topic named `topic1` and a consumer named `c1` are used.

- Reading a single message with output to the terminal: If the topic doesn't contain new messages for this consumer, the command terminates with no data output:

```
ydb -p quickstart topic read topic1 -c c1
```

- Waiting for and reading a single message written to a file named `message.bin`. The command keeps running until new messages appear in the topic for this consumer. However, you can terminate it with `Ctrl+C`:

```
ydb -p quickstart topic read topic1 -c c1 -w -f message.bin
```

- Viewing information about messages waiting to be handled by the consumer without committing them. Up to 10 first messages are output:

```
ydb -p quickstart topic read topic1 -c c1 --format pretty --commit false
```

- Output messages to the terminal as they appear, using newline delimiter characters and transforming messages into Base64. The command will be running until you terminate it with `Ctrl+C`:

```
ydb -p quickstart topic read topic1 -c c1 -w --format newline-delimited --transform base64
```

- Track when new messages with the `ERROR` text appear in the topic and output them to the terminal once they arrive:

```
ydb -p quickstart topic read topic1 -c c1 --format newline-delimited -w | grep ERROR
```

- Receive another non-empty batch of no more than 150 messages transformed into base64, delimited with newline characters, and written to the `batch.txt` file:

```
ydb -p quickstart topic read topic1 -c c1 \
  --format newline-delimited -w --limit 150 \
  --transform base64 -f batch.txt
```

- Examples of YDB CLI command integration

Writing messages to a topic

The `topic write` command writes messages to a topic from a file or `stdin`:

```
ydb [connection options] topic write <topic-path> \
  [--file STR] [--format STR] [--transform STR] \
  [additional parameters...]
```

where [connection options] are database connection options

Parameters

Basic parameters

`<topic-path>`: Topic path, the only required parameter.

`--file VAL` (`-f VAL`): Read a stream of incoming messages and write them to a topic from the specified file. If not set, messages are read from `stdin`.

`--format STR`: Format of the incoming message stream. Supported formats:

Name	Description
`single-message` (default)	The entire input stream is treated as a single message to be written to the topic.
`newline-delimited`	A stream at the input contains multiple messages delimited with the `0x0A` newline character.

`--transform VAL`: Method for transforming messages.

- Defaults to `none`.
- Possible values:
  - `base64`: Decode each message in the input stream from Base64 and write the output to the topic. If decoding fails, the command is aborted with an error.
  - `none`: Write the contents of a message from the input stream to the topic byte by byte without transforming them.

Additional parameters

Name	Description
`--delimiter STR`	Delimiter byte. The input stream is delimited into messages with the specified byte. Specified only if no `--format` is set. Specified as an escaped string.
`--message-group-id STR`	Message group string ID. If not set, all messages generated from the input stream are assigned the same ID value as a hexadecimal string representation of a random three-byte integer.
`--codec STR`	Codec used for message compression on the client before sending them to the server. Possible values: `RAW` (no compression, default), `GZIP`, and `ZSTD`. Compression causes higher CPU utilization on the client when reading and writing messages, but usually lets you reduce the volume of data transferred over the network and stored. When consumers read messages, they're automatically decompressed with the codec used when writing them, without specifying any special options. Make sure the specified codec is listed in the topic parameters as supported.

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

All the examples given below use a topic named `topic1`.

- Writing a terminal input to a single message Once the command is run, you can type any multi-line text and press `Ctrl+D` to input it.

  ```
  ydb -p quickstart topic write topic1
  ```

- Writing the contents of the `message.bin` file to a single message compressed with the GZIP codec

  ```
  ydb -p quickstart topic write topic1 -f message.bin --codec GZIP
  ```

- Writing the contents of the `example.txt` file delimited into messages line by line

  ```
  ydb -p quickstart topic write topic1 -f example.txt --format newline-delimited
  ```

- Writing a resource downloaded via HTTP and delimited into messages with tab characters

  ```
  curl http://example.com/resource | ydb -p quickstart topic write topic1 --delimiter "\t"
  ```

- Examples of YDB CLI command integration

Message pipeline processing

The use of the `topic read` and `topic write` commands with standard I/O devices and support for reading messages in streaming mode lets you build full-featured integration scenarios with message transfer across topics and their conversion. This section describes a number of these scenarios.

- Transferring a single message from `topic1` in the `quickstart` database to `topic2` in `db2`, waiting for it to appear in the source topic

```
ydb -p quickstart topic read topic1 -c c1 -w | ydb -p db2 topic write topic2
```

- Transferring all one-line messages that appear in `topic1` in the `quickstart` database to `topic2` in `db2` in background mode. You can use this scenario if it's guaranteed that there are no `0x0A` bytes (newline) in source messages.

```
ydb -p quickstart topic read topic1 -c c1 --format newline-delimited -w | \
ydb -p db2 topic write topic2 --format newline-delimited
```

- Transferring an exact binary copy of all messages that appear in `topic1` in the `quickstart` database to `topic2` in `db2` in background mode with base64-encoding of messages in the transfer stream.

```
ydb -p quickstart topic read topic1 -c c1 --format newline-delimited -w --transform base64 | \
ydb -p quickstart topic write topic2 --format newline-delimited --transform base64
```

- Transferring a limited batch of one-line messages filtered by the `ERROR` substring

```
ydb -p quickstart topic read topic1 -c c1 --format newline-delimited | \
grep ERROR | \
ydb -p db2 topic write topic2 --format newline-delimited
```

- Writing YQL query results as messages to `topic1`

```
ydb -p quickstart yql -s "select * from series" --format json-unicode | \
ydb -p quickstart topic write topic1 --format newline-delimited
```

Running an SQL query with the transmission of messages from the topic as parameters

- Running a YQL, passing each message read from `topic1` as a parameter

```
ydb -p quickstart topic read topic1 -c c1 --format newline-delimited -w | \
ydb -p quickstart sql -s 'declare $s as String;select Len($s) as Bytes' \
--input-framing newline-delimited --input-param-name s --input-format raw
```

- Running a YQL query involving adaptive batching of parameters from messages read from `topic1`

```
ydb -p quickstart topic read topic1 -c c1 --format newline-delimited -w | \
ydb -p quickstart sql \
-s 'declare $s as List<String>;select ListLength($s) as Count, $s as Items' \
--input-framing newline-delimited --input-param-name s --input-format raw \
--input-batch adaptive
```

Overview

You can use the following YDB CLI commands to run queries:

- ydb sql: A single command to execute any SQL query supported by YDB.
- ydb: Switches the console to interactive mode to execute queries.

Query parameterization is explained separately.

Query execution

You can use the `ydb sql` subcommand to execute an SQL query. The query can be of any type (DDL, DML, etc.) and can consist of several subqueries. The `ydb sql` subcommand establishes a streaming connection and retrieves data through it. With in-stream query execution, no limit is imposed on the amount of data read. Data can also be written using this command, which is more efficient when executing repeated queries with data passed through parameters.

General format of the command:

```
ydb [global options...] sql [options...]
```

- `global options` : Global parameters.
- `options` : Subcommand parameters.

View the description of the query execution command:

```
ydb sql --help
```

Parameters of the subcommand

Name	Description
`-h`, `--help`	Print general usage help.
`-hh`	Print complete usage help, including specific commands not shown with `--help`.
`-s`, `--script`	Script (query) text to execute.
`-f`, `--file`	Path to a file with query text to execute. Path `-` means reading query text from `stdin` which disables passing parameters via `stdin`.
`--stats`	Statistics mode. Available options: • `none` (default): Do not collect statistics. • `basic` : Collect aggregated statistics for updates and deletes per table. • `full` : Include execution statistics and plan in addition to `basic`. • `profile` : Collect detailed execution statistics, including statistics for individual tasks and channels.
`--explain`	Execute an explain request for the query. Displays the query's logical plan. The query is not actually executed and does not affect database data.
`--explain-ast`	Same as `--explain`, but in addition to the query's logical plan, an abstract syntax tree (AST) is printed. The AST section contains a representation in the internal miniKQL language.
`--explain-analyze`	Execute the query in `EXPLAIN ANALYZE` mode. Displays the query execution plan. Query results are ignored. **Important note: The query is actually executed, so any changes will be applied to the database**.
`--format`	Output format. Available options: • `pretty` (default): Human-readable format. • `json-unicode` : JSON output with binary strings Unicode-encoded and each JSON string in a separate line. • `json-unicode-array` : JSON output with binary strings Unicode-encoded and the result output as an array of JSON strings with each JSON string in a separate line. • `json-base64` : JSON output with binary strings Base64-encoded and each JSON string in a separate line. • `json-base64-array` : JSON output with binary strings Base64-encoded and the result output as an array of JSON strings with each JSON string in a separate line; • `parquet` : Output in Apache Parquet format. • `csv` : Output in CSV format. • `tsv` : Output in TSV format.

Working with parameterized queries

For a detailed description with examples on how to use parameterized queries, see Executing parameterized queries.

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Running DDL and DML together in a single query is not supported.

```
# Creating a table
ydb -p quickstart sql -s '
  CREATE TABLE series (
    series_id Uint64,
    title Utf8,
    series_info Utf8,
    release_date Date,
    PRIMARY KEY (series_id)
  );
'

# Populating with data and retrieving a sample
ydb -p quickstart sql -s '
    UPSERT INTO series (series_id, title, series_info, release_date)
    VALUES (1, "Title1", "Info1", Cast("2023-04-20" as Date));
    SELECT * FROM series;
'

# Adding an index
ydb -p quickstart sql -s '
    ALTER TABLE series
    ADD INDEX title_idx GLOBAL ON (title);
'
```

Command output:

```
┌──────────────┬────────────┬──────────────┬────────────┐
| release_date | series_id | series_info | title    |
├──────────────┼────────────┼──────────────┼────────────┤
| "2023-04-20" | 1         | "Info1"     | "Title1" |
└──────────────┴────────────┴──────────────┴────────────┘
```

To run a query from a file (for example, script1.yql) with JSON output

```
ydb -p quickstart sql -f script1.yql --format json-unicode
```

Command output:

```
{"release_date":"2023-04-20","series_id":1,"series_info":"Info1","title":"Title1"}
```

Examples of passing parameters to scripts are given in the article on passing parameters to query execution commands.

Executing parameterized queries

Overview

YDB CLI supports executing parameterized queries. To work with parameters, the query text must contain their definitions using the YQL `DECLARE` command.

The main tool for executing parameterized queries in YDB CLI is the ydb sql command.

Why use parameterized queries?

Using parameterized queries provides several important benefits:

- **Improved performance:** Parameterized queries significantly improve performance when executing many similar operations that differ only in input values. This is due to query plan caching. After the first compilation of a query, its plan is stored in the LRU cache of the YDB node. All subsequent calls of the same query with new parameters skip the compilation stage and start executing immediately, saving time and resources.
- **Protection against SQL injection:** Another important advantage of using parameterized queries is protection against SQL injection. This security feature ensures proper handling of input data, reducing the risk of malicious code execution.

Single query execution

This command supports passing parameters via command-line options, a file, and also via `stdin`. When passing parameters via `stdin` or a file, repeated streaming execution of the query with different parameter values and batching capability is supported. For this purpose, the ydb sql command provides the following parameters:

Name	Description
`-p, --param`	Value of a single query parameter in `$name=value` or `name=value` format, where `name` is the parameter name and `value` is its value (a valid JSON value).
`--input-file`	Name of a file in JSON format encoded in UTF-8, which contains parameter values mapped to query parameters by key names. At most one parameter file can be used.
`--input-format`	Format for representing parameter values. Applies to all methods of passing them (via a command parameter, file, or `stdin`). Possible values: • `json` (default): JSON format. • `csv` — CSV format. By default, parameter names must be in the CSV file header. For a single query execution, only one row is allowed in the file, not counting the header. • `tsv` — TSV format. • `raw`: The input stream from `stdin` or `--input-file` contains only the parameter value as binary data. The parameter name must be specified with the `--input-param-name` option.
`--input-binary-strings`	Encoding format for parameter values of the 'binary string' type (`DECLARE $par AS String`). Specifies how binary strings from the input stream should be interpreted. Possible values: • `unicode`: Each byte in a binary string that is not a printable ASCII character (codes 32-126) must be encoded in UTF-8. • `base64`: Binary strings are represented in Base64 encoding. This allows passing binary data, which YDB CLI will decode from Base64.

If values are specified for all parameters that do not allow `NULL` (i.e., with the NOT NULL type), as part of the `DECLARE` statement, the query will be executed on the server. If a value is missing for at least one such parameter, the command will fail with an error and the message "Parameter value not set".

More specific options for using input parameters

The following options are not shown in the `--help` output. Their description can only be seen in the `-hh` output.

Name	Description
`--input-framing`	Sets the framing for the input stream (`stdin` or `--input-file`). Determines how the input stream is split into separate parameter sets. Possible values: • `no-framing` (default): One parameter set is expected from the input stream, the query is executed once. • `newline-delimited`: A newline character marks the end of one parameter set in the input stream, separating it from the next. A parameter set is considered complete each time a newline character is received in the input stream.
`--input-param-name`	The name of the parameter whose value is passed to the input stream. Specified without the `$` character. Required when using the `raw` format in `--input-format`. When used with the JSON format, the input stream is interpreted not as a JSON document, but as a JSON value, with the value passed to the parameter with the specified name.
`--input-columns`	A string with column names replacing the header of the CSV/TSV document read from the input stream. When this option is specified, the header is considered absent. The option is only valid with CSV and TSV formats.
`--input-skip-rows`	The number of lines from the beginning of the data read from stdin to skip, not including the header line if present. The option is only valid with stdin formats CSV and TSV.

`--input-batch`	Batching mode for parameter set values received from the input stream (`stdin` or `--input-file`). Possible values: • `iterative` (default): Batching is disabled. The query is executed for each parameter set (exactly once if option `--input-framing` uses `no-framing`) • `full` : Full batch. The query is executed once after reading the input stream is complete; all received parameter sets are wrapped into `List<...>` , the parameter name is set by option `--input-param-name` • `adaptive` : Adaptive batching. The query is executed each time a limit on the number of parameter sets in a single query (`--input-batch-max-rows`) or a processing delay limit (`--input-batch-max-delay`) is triggered. All parameter sets received up to that point are wrapped into `List<...>` , the parameter name is set by option `--input-param-name` .
`--input-batch-max-rows`	Maximum number of parameter sets in a batch for adaptive batching mode. The next batch will be sent for execution together with the query if the number of data sets in it reaches the specified value. Setting to `0` removes the limit. Default value — `1000` . Parameters are passed to the query without streaming, and the total size of a single gRPC request that includes parameter values has an upper limit of about 5 MB.
`--input-batch-max-delay`	Maximum delay for sending a received parameter set for processing in adaptive batching mode. Specified as a number with a time dimension - `s` (seconds), `ms` (milliseconds), `m` (minutes), etc. Default value — `1s` (1 second). YDB CLI will count time from the moment the first parameter set for a batch is received and will send the accumulated batch for execution as soon as the time exceeds the specified value. This parameter allows efficient batching in case of an unpredictable rate of new parameter sets arriving at `stdin` .

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Passing a single parameter value

On the command line, via the `--param` option:

```
ydb -p quickstart sql -s 'DECLARE $a AS Int64; SELECT $a' --param '$a=10'
```

Via a file in JSON format (which is used by default):

```
echo '{"a":10}' > p1.json
ydb -p quickstart sql -s 'DECLARE $a AS Int64; SELECT $a' --input-file p1.json
```

Via `stdin` , passing a JSON string as a single parameter set:

```
echo '{"a":10}' | ydb -p quickstart sql -s 'DECLARE $a AS Int64; SELECT $a'
```

Via `stdin` , passing only the parameter value and specifying the parameter name via the `--input-param-name` option:

```
echo '10' | ydb -p quickstart sql -s 'DECLARE $a AS Int64; SELECT $a' --input-param-name a
```

Passing parameter values of different types from multiple sources

```
# Create a JSON file with fields 'a', 'b', and 'x', where 'x' will be ignored in the query
echo '{ "a":10, "b":"Some text", "x":"Ignore me" }' > p1.json

# Run the query using ydb-cli, passing in 'a' and 'b' from the input file, and 'c' as a direct parameter
ydb -p quickstart sql \
  -s 'DECLARE $a AS Int64;
      DECLARE $b AS Utf8;
      DECLARE $c AS Int64;

      SELECT $a, $b, $c' \
  --input-file p1.json \
  --param '$c=30'
```

Command output:

```
┌─────────┬─────────────┬─────────┐
| column0 | column1     | column2 |
├─────────┼─────────────┼─────────┤
| 10      | "Some text" | 30      |
└─────────┴─────────────┴─────────┘
```

Passing binary strings in Base64 encoding

```
ydb -p quickstart sql \
  -s 'DECLARE $a AS String;
      SELECT $a' \
  --input-format json \
  --input-binary-strings base64 \
  --param '$a="SGVsbG8sIHdvcmxkCg=="'
```

Command output:

```
┌──────────────────────┐
| column0              |
├──────────────────────┤
| "Hello, world\n" |
└──────────────────────┘
```

Direct binary content passing

```
curl -Ls http://ydb.tech/docs/en | ydb -p quickstart sql \
  -s 'DECLARE $a AS String;
      SELECT LEN($a)' \
  --input-format raw \
  --input-param-name a
```

Command output (exact number of bytes may differ):

```
┌──────────┐
| column0 |
├──────────┤
| 66426   |
└──────────┘
```

Passing a file in CSV format

```
echo '10,Some text' | ydb -p quickstart sql \
  -s 'DECLARE $a AS Int32;
      DECLARE $b AS String;
      SELECT $a, $b' \
  --input-format csv \
  --input-columns 'a,b'
```

Command output:

```
┌──────────┬─────────────┐
| column0 | column1     |
├──────────┼─────────────┤
| 10      | "Some text" |
└──────────┴─────────────┘
```

Iterative streaming processing

YDB CLI supports the ability to execute a query multiple times with different sets of parameter values, when they are passed via `stdin` **or** an input file (not simultaneously). In this case, the database connection is established once, and the query execution plan is cached, which significantly improves the performance of this approach compared to separate CLI invocations.

To use this feature, you need to pass different sets of values for the same parameters one after another to the command input, telling YDB CLI the rule by which these sets can be separated from each other.

The query is executed as many times as the number of parameter value sets received. Each set received via the input stream (`stdin` or `--input-file`) is merged with the parameter values defined via the `--param` options. Command execution will finish after the input stream ends. Each query is executed in its own transaction.

The rule for separating parameter sets from each other (framing) complements the description of the parameter representation format on the input stream, specified by the `--input--framing` parameter:

Name	Description
`--input-framing`	Specifies framing for the input stream (file or `stdin`). Possible values: • `no-framing` (default) — one parameter set is expected at the input, the query is executed once after reading the stream completes. • `newline-delimited` — a newline character marks the end of one parameter set at the input, separating it from the next. The query is executed each time a newline character is received.

Warning

When using a newline character as a separator for parameter sets, you must ensure it is absent inside the parameter sets. Quoting text does not make a newline inside such text valid. Multiline JSON documents are not allowed.

Example

Streaming processing of multiple parameter sets

JSON

Suppose we need to execute the query three times, with the following sets of parameter values `a` and `b`:

1. `a` = 10, `b` = 20
2. `a` = 15, `b` = 25
3. `a` = 35, `b` = 48

Let's create a file that will contain lines with JSON representation of these sets:

```
echo -e '{"a":10,"b":20}\n{"a":15,"b":25}\n{"a":35,"b":48}' | tee par1.txt
```

Command output:

```
{"a":10,"b":20}
{"a":15,"b":25}
{"a":35,"b":48}
```

Execute the query by passing the contents of this file to `stdin`, with output formatting in JSON:

```
cat par1.txt | \
ydb -p quickstart sql \
  -s 'DECLARE $a AS Int64;
      DECLARE $b AS Int64;
      SELECT $a+$b' \
  --input-framing newline-delimited \
  --format json-unicode
```

Command output:

```
{"column0":30}
{"column0":40}
{"column0":83}
```

Or simply by passing the file name to the `--input-file` option:

```
ydb -p quickstart sql \
  -s 'DECLARE $a AS Int64;
      DECLARE $b AS Int64;
      SELECT $a + $b' \
  --input-file par1.txt \
  --input-framing newline-delimited \
  --format json-unicode
```

Command output:

```
{"column0":30}
{"column0":40}
{"column0":83}
```

The result obtained in this format can be used as input to the command executing the next query.

CSV

Suppose we need to execute the query three times, with the following sets of parameter values `a` and `b`:

1. `a` = 10, `b` = 20
2. `a` = 15, `b` = 25
3. `a` = 35, `b` = 48

Let's create a file with sets of parameter values in CSV format:

```
echo -e 'a,b\n10,20\n15,25\n35,48' | tee par1.txt
```

Command output:

```
a,b
10,20
15,25
35,48
```

Let's execute the query by passing the contents of this file to `stdin`, with output formatting in CSV:

```
cat par1.txt | \
ydb -p quickstart sql \
  -s 'DECLARE $a AS Int64;
      DECLARE $b AS Int64;
      SELECT $a + $b' \
  --input-format csv \
  --input-framing newline-delimited \
  --format csv
```

Command output:

```
30
40
83
```

Or simply by passing the file name to the `--input-file` option:

```
ydb -p quickstart sql \
  -s 'DECLARE $a AS Int64;
      DECLARE $b AS Int64;
      SELECT $a + $b' \
  --input-file par1.txt \
  --input-format csv \
  --input-framing newline-delimited \
  --format csv
```

Command output:

```
30
40
83
```

The result obtained in this format can be used as input to the command executing the next query, by specifying the header data in CSV format with the `--input-columns` option.

TSV

Suppose we need to execute the query three times, with the following sets of parameter values `a` and `b`:

1. `a` = 10, `b` = row1
2. `a` = 15, `b` = row 2
3. `a` = 35, `b` = "row"\n3

Let's create a file with sets of parameter values in TSV format:

```
echo -e 'a\tb\n10\t20\n15\t25\n35\t48' | tee par1.txt
```

Command output:

```
a  b
10 20
15 25
35 48
```

Let's execute the query by passing the contents of this file to `stdin`, with output formatting in TSV:

```
cat par1.txt | \
ydb -p quickstart sql \
  -s 'DECLARE $a AS Int64;
      DECLARE $b AS Utf8;
      SELECT $a, $b' \
  --input-framing newline-delimited \
  --input-format tsv \
  --format tsv
```

Command output:

```
30
40
83
```

Or simply by passing the file name to the `--input-file` option:

```
ydb -p quickstart sql \
  -s 'DECLARE $a AS Int64;
      DECLARE $b AS Int64;
      SELECT $a + $b' \
  --input-file par1.txt \
  --input-format tsv \
  --input-framing newline-delimited \
  --format tsv
```

Command output:

```
30
40
83
```

The result obtained in this format can be used as input to the command executing the next query, by specifying the header data in TSV format with the `--input-columns` option.

Stream processing with merging parameter values from different sources

Suppose we need to execute the query three times, with the following sets of parameter values `a` and `b`:

1. `a` = 10, `b` = 100
2. `a` = 15, `b` = 100
3. `a` = 35, `b` = 100

```
echo -e '10\n15\n35' | \
ydb -p quickstart sql \
  -s 'DECLARE $a AS Int64;
      DECLARE $b AS Int64;
      SELECT $a + $b AS sum1' \
  --param '$b=100' \
  --input-framing newline-delimited \
  --input-param-name a \
  --format json-unicode
```

Command output:

```
{"sum1":110}
{"sum1":115}
{"sum1":135}
```

Batch stream processing

The YDB CLI supports automatic conversion of parameter sets into `List<...>`, allowing a single server request to process multiple parameter sets in one transaction, which can further significantly improve performance compared to executing queries "one by one".

Two batching modes are supported:

- Full (`full`)
- Adaptive (`adaptive`)

Full batching mode

The full (`full`) mode is a simplified batching option where the query is executed once, wrapping all parameter sets received from the input stream into `List<...>`. If the query size turns out to be too large, an error will be raised.

This batching option is necessary when atomicity must be guaranteed by applying all parameters in a single transaction.

Adaptive batching mode

When operating in adaptive (`adaptive`) mode, the input stream processing is split into multiple transactions, with automatic selection of the batch size for each of them.

This mode allows efficient processing of a wide range of input loads, with unpredictable or infinite amounts of data, as well as unpredictable or rapidly changing input rates. In particular, this profile is typical when feeding the output of another command to `stdin` via the `|` operator.

Adaptive mode solves two main problems of dynamic stream processing:

1. Limiting the maximum batch size.
2. Limiting the maximum data processing delay.

Syntax

To use the batching feature, you need to declare a parameter of type `List<...>` or `List<Struct<...>>` in the DECLARE section of the query, and select the mode with the following parameter:

Name	Description
`--input-batch`	Mode for batching values of parameter sets obtained from the input stream (`stdin` or `--input-file`). Possible values: • `iterative` (default): Batching is disabled. The query is executed for each parameter set (exactly once if the `--input-framing` option uses `no-framing`) • `full`: Full batch. The query will run once after the input stream is read, all received parameter sets are wrapped in `List<...>`, the parameter name is set by the `--input-param-name` option • `adaptive`: Adaptive batching. The query is executed each time the limit on the number of parameter sets in one query (`--input-batch-max-rows`) or the processing delay (`--input-batch-max-delay`) is triggered. All parameter sets received by this point are wrapped in `List<...>`, the parameter name is set by the `--input-param-name` option.

Additional parameters are available in adaptive batching mode:

Name	Description

`--input-batch-max-rows`	Maximum number of parameter sets in a batch for adaptive batching mode. The next batch will be sent for execution together with the query if the number of data sets in it has reached the specified value. Setting to `0` removes the limit. Default value — `1000`. Parameters are passed to the query without streaming, and the total size of a single gRPC request that includes parameter values has an upper limit of about 5 MB.
`--input-batch-max-delay`	Maximum delay for sending a received parameter set for processing in adaptive batching mode. Specified as a number with a time dimension - `s` (seconds), `ms` (milliseconds), `m` (minutes), etc. Default value — `1s` (1 second). The YDB CLI will count time from the moment the first parameter set for a batch is received and will send the accumulated batch for execution as soon as the time exceeds the specified value. This parameter allows efficient batching in case of an unpredictable rate of new parameter sets arriving at `stdin`.

Examples - full batch processing

```
echo -e '{"a":10,"b":20}\n{"a":15,"b":25}\n{"a":35,"b":48}' | \
ydb -p quickstart sql \
  -s 'DECLARE $x AS List<Struct<a:Int64,b:Int64>>;
      SELECT ListLength($x), $x' \
  --input-framing newline-delimited \
  --input-param-name x \
  --input-batch full
```

Command output:

```
┌──────────┬──────────────────────────────────────────────────────────┐
| column0 | column1                                                  |
├──────────┼──────────────────────────────────────────────────────────┤
| 3       | [{"a":10,"b":20},{"a":15,"b":25},{"a":35,"b":48}] |
└──────────┴──────────────────────────────────────────────────────────┘
```

Examples - adaptive batch processing

Limiting the maximum processing delay

To demonstrate adaptive batching with the processing delay limit trigger, the first line of the command below generates 1000 lines with a 0.2 second delay in `stdout`, which are passed to the `stdin` query execution command. The query execution command, in turn, displays parameter batches in each subsequent query call.

```
for i in $(seq 1 1000); do echo "Line$i"; sleep 0.2; done | \
ydb -p quickstart sql \
  -s 'DECLARE $x AS List<Utf8>;
      SELECT ListLength($x), $x' \
  --input-framing newline-delimited \
  --input-format raw \
  --input-param-name x \
  --input-batch adaptive
```

Command output (exact values may differ):

```
┌──────────┬──────────────────────────────────────────────────────────
```

```
for i in $(seq 1 200); do echo "Line$i"; done | \
ydb -p quickstart sql \
  -s 'DECLARE $x AS List<Utf8>;
      DECLARE $p2 AS Int64;
      SELECT ListLength($x) AS count, $p2 AS p2, $x AS items' \
  --input-framing newline-delimited \
  --input-format raw \
  --input-param-name x \
  --input-batch adaptive \
  --input-batch-max-rows 20 \
  --param '$p2=10' \
  --format json-unicode
```

Command output:

```
{"count":20,"p2":10,"items":["Line1","Line2","Line3","Line4","Line5","Line6","Line7","Line8","Line9","Line1
0","Line11","Line12","Line13","Line14","Line15","Line16","Line17","Line18","Line19","Line20"]}
{"count":20,"p2":10,"items":["Line21","Line22","Line23","Line24","Line25","Line26","Line27","Line28","Line2
9","Line30","Line31","Line32","Line33","Line34","Line35","Line36","Line37","Line38","Line39","Line40"]}
...
{"count":20,"p2":10,"items":["Line161","Line162","Line163","Line164","Line165","Line166","Line167","Line16
8","Line169","Line170","Line171","Line172","Line173","Line174","Line175","Line176","Line177","Line178","Line1
79","Line180"]}
{"count":20,"p2":10,"items":["Line181","Line182","Line183","Line184","Line185","Line186","Line187","Line18
8","Line189","Line190","Line191","Line192","Line193","Line194","Line195","Line196","Line197","Line198","Line1
99","Line200"]}
```

Deleting multiple records from a row table YDB by primary keys

If you try to delete a large number of rows from a large table using a simple `DELETE FROM large_table WHERE id > 10;` query, you may encounter an error due to exceeding the limit on the number of records in a transaction. This example shows how to delete an unlimited number of records from YDB tables without violating this limit.
Let's create a test row table:

```
ydb -p quickstart sql -s 'CREATE TABLE test_delete_1(id UInt64 NOT NULL, PRIMARY KEY (id))'
```

Let's insert 100,000 records into it:

```
for i in $(seq 1 100000); do echo "$i";done | \
ydb -p quickstart import file csv -p test_delete_1
```

Let's delete all records with `id` values greater than 10:

```
ydb -p quickstart sql \
  -s 'SELECT t.id FROM test_delete_1 AS t WHERE t.id > 10' \
  --format json-unicode | \
ydb -p quickstart sql \
  -s 'DECLARE $lines AS List<Struct<id:UInt64>>;
      DELETE FROM test_delete_1 WHERE id IN (SELECT tl.id FROM AS_TABLE($lines) AS tl)' \
  --input-framing newline-delimited \
  --input-param-name lines \
  --input-batch adaptive \
  --input-batch-max-rows 10000
```

Processing messages read from a topic

Examples of processing messages read from a topic are given in the article Running an SQL query with the transmission of messages from the topic as parameters.

Interactive query execution mode

Overview

Executing the `ydb` command without subcommands launches the interactive query execution mode. After that, you can enter queries directly into the console or terminal. When you enter a newline character, the query text is considered complete, and query execution begins. The query text can be either a YQL query or a special command.

General format of the command:

```
ydb [global options...]
```

- `global options` — global parameters.

> **Note**
>
> Note that the command still requires connection parameters to be set. You can supply them by having the default profile, via an explicitly specified profile, or by passing a set of connection parameters.

Example usage:

The interactive query execution mode in YDB CLI offers the following features:

- Syntax highlighting
- Hotkeys
- Query history
- Auto completion
- Special commands
- AI assistant mode

Syntax highlighting

Interactive mode supports YQL syntax highlighting, which helps to better understand the query structure. Different colors are used for the following groups of elements:

- YQL keywords (`SELECT`, `FROM`, `WHERE`, `INSERT`, `UPDATE`, and others)
- Table and column names
- String literals (text in quotes)
- Numeric literals
- Operators (`=`, `<`, `>`, `+`, `-`, and others)
- Special characters (brackets, commas, dots)
- Comments

Hotkeys

You can use these hotkeys while working in the interactive mode:

Hotkey	Description
`Up arrow`	Shows the previous query from history.
`Down arrow`	Shows the next query from history.
`TAB`	Completes the current word based on YQL syntax.

`CTRL + R`	Searches for a query in history containing a specified substring.
`CTRL + T`	Switches between YQL and AI modes.
`CTRL + D`	Exits interactive mode.

Query history

You can navigate through the query history using the up and down arrow keys:

History is stored locally and persists between CLI launches.

A query search function (`CTRL + R`) is also supported:

Auto completion

Auto completion helps you write queries more efficiently. While typing, it suggests possible completions for the current word based on YQL syntax.

It also searches for schema object names in the database where possible.

There are two types of suggestions: auto completion by pressing the `TAB` key and interactive hints.

Auto completion by pressing the `TAB` key

While in interactive mode, pressing the `TAB` key shows a list of suggestions for completing the current word according to the YQL syntax.

Continue typing to narrow down the list of suitable candidates.

If there is only one available option, pressing `TAB` will automatically complete the current word.

If all available options share a common prefix, pressing `TAB` will automatically insert it.

Interactive hints

While typing in interactive mode, a list of hints appears under the cursor, showing the first four suggestions for completing the current word according to the YQL grammar.

This feature provides quick guidance without overwhelming you with all possible options, helping you stay on track while writing queries.

Special commands

Special commands are CLI-specific commands and are not part of the YQL syntax. Their purpose is to perform various functions that cannot be accomplished through a YQL query.

Command	Description
`SET param = value`	Sets the value of the internal variable `param` to `value`.
`EXPLAIN query-text`	Outputs the query plan for `query-text`. Equivalent to the command ydb table query explain.
`EXPLAIN AST query-text`	Outputs the query plan for `query-text` along with the AST. Equivalent to the command ydb table query explain --ast.

List of internal variables

Internal variables determine the behavior of commands and are set using the special command `SET`.

Variable	Description
`stats`	The statistics collection mode for subsequent queries. Acceptable values: • `none` (default): Do not collect. • `basic`: Collect statistics. • `full`: Collect statistics and query plan.

Example

Executing a query in the `full` statistics collection mode:

```
$ ydb
ydb> SET stats = full
ydb> select * from table1 limit 1

AI assistant mode

The interactive mode includes an AI assistant mode — a conversational agent powered by a large language model that helps you explore the database structure, write and run YQL queries, search the documentation, and invoke YDB CLI commands. To switch between YQL and AI modes, press `Ctrl + T` or use the `/switch` command.

For more details, see AI assistant mode.

AI assistant mode

The YDB CLI interactive query execution mode includes an AI assistant mode — a conversational agent powered by a large language model (LLM). The assistant understands natural-language requests and helps you work with the database: explore its structure, write and run YQL queries, explain query plans, search the documentation, and invoke YDB CLI commands.

> **Warning**
>
> The assistant calls an external large language model API that you specify yourself. The conversation contents, including the schema structure and query results that the assistant chooses to pass to the model, are sent to that API. Do not use this mode with sensitive data if your policies prohibit it. The YDB CLI does not provide a language model or an access key — you must obtain them from the provider of your choice.

Switching to AI mode

The interactive mode runs in one of two submodes:

- **YQL** — entering and running YQL queries (used by default on the first launch);
- **AI** — a dialog with the AI assistant.

Start the interactive mode by running the `ydb` command without a subcommand and with the required connection parameters:

```
ydb [global options...]
```

The active submode is shown in the command-line prompt (`YQL>` or `AI>`). To switch between submodes, press `Ctrl + T` or use the `/switch` command. The YDB CLI remembers the last used submode and opens it on the next launch.

Setting up an AI profile

The assistant requires an AI profile — a set of connection parameters for the language model API. The first time you switch to AI mode, if no profiles exist yet, the YDB CLI offers to create one and guides you through the setup step by step:

Parameter	Description
API endpoint	The URL of the language model API. It must start with `http://` or `https://` (for example, `https://api.openai.com/v1/`). The YDB CLI verifies the connection to the specified address.
API type	The API type: • **OpenAI-compatible** — for models with an OpenAI-compatible API; • **Anthropic** — for the Anthropic API.
API token	The API access token. It is stored in the configuration file. You can leave the field empty and pass the token via the `YDB_CLI_AI_TOKEN` environment variable.
Model name	The model name. If the API allows it, the YDB CLI requests the list of available models; the name can also be entered manually. An empty value means the model name is not passed in requests.
Profile display name	The display name under which the profile is saved and shown during selection.

After setup, the profile is saved to the configuration file and becomes active. To switch the active profile or create a new one, use the `/model` command.

Working with the assistant

In AI mode, type a natural-language message and press `Enter` to send it (`Ctrl + Enter` inserts a newline). The assistant analyzes your request and, when needed, calls tools to work with the database:

Capability	Modifies data	Confirmation
Listing schema objects under a given path	No	Not required
Describing a schema object (table, topic, and so on)	No	Not required
Getting a YQL query plan (`EXPLAIN`)	No	Not required
Searching the YDB documentation	No	Not required
Getting help on YDB CLI commands	No	Not required
Running a YQL query	Yes	Required
Running a shell command	Yes	Required

The assistant keeps the conversation context: subsequent messages take previous ones into account. You can clear the context with the `/config` command.

Action confirmation

Before performing an action that may modify data — running a YQL query or a shell command — the assistant asks for confirmation and offers the following options:

- **Approve execution** — run the query or command as is;
- **Edit query** / **Edit command** — edit the query or command text before running it;
- **Abort operation** — cancel the execution (and continue working in the same context).

Commands

The following commands are available in AI mode:

Command	Description
`/help`	Show help for AI mode and the list of hotkeys.
`/model`	Select another AI profile or create a new one.
`/config`	Change session settings: clear the conversation context, switch or edit the active profile, remove a profile.
`/switch`	Switch to YQL mode (equivalent to `Ctrl + T`).

Configuration file

AI profiles and AI mode settings are stored in a YAML file. By default it is `~/.config/ydb/ai_profiles.yaml`; the path can be overridden with the `YDB_CLI_AI_PROFILE_FILE` environment variable. The file contains the list of profiles, the ID of the active profile, and the current interactive submode. You usually do not need to edit it manually — manage profiles via the `/model` and `/config` commands.

Note

A token entered directly during profile setup is stored in the configuration file. The YDB CLI restricts the file's permissions so that only the owner — the user who runs the CLI — can read and modify it (on Unix systems, mode `0600`). If you prefer not to store the token on disk, leave the token field empty and pass it via the `YDB_CLI_AI_TOKEN` environment variable.

Environment variables

Variable	Description
`YDB_CLI_AI_TOKEN`	The access token for the language model API. Used if the token is not set in the active profile.
`YDB_CLI_AI_PROFILE_FILE`	The path to the AI profiles configuration file. Defaults to `~/.config/ydb/ai_profiles.yaml`. Lets you use a separate profile set or a non-default file location, for example in automated scenarios.
`YDB_CLI_AI_DISABLE_HISTORY`	If set, the AI mode message history is not stored on disk between launches. Use it when the conversation with the assistant should not be persisted to disk.

Running scan queries

> **Warning**
>
> Using `ScanQuery` is not recommended for new scenarios. Use standard mechanisms to execute queries.
>
> For more details, see the Executing queries section.
>
> The exception is executing long-running (over 5 minutes) queries against row tables. In this case, we still recommend using `ScanQuery`, as standard query execution mechanisms do not yet fully support this scenario.

To run a query via Scan Queries using YDB CLI, add the `-t scan` flag to the `ydb table query execute` command.

Run a query against the data:

```
ydb table query execute -t scan \
 --query "SELECT season_id, episode_id, title \
 FROM episodes \
 WHERE series_id = 1 AND season_id > 1 \
 ORDER BY season_id, episode_id \
 LIMIT 3"
```

Where:

- `--query` — query text.

Result:

```
┌───────────┬────────────┬──────────────────────────────────┐
| season_id | episode_id | title |
├───────────┼────────────┼──────────────────────────────────┤
| 2 | 1 | "The Work Outing" |
├───────────┼────────────┼──────────────────────────────────┤
| 2 | 2 | "Return of the Golden Child" |
├───────────┼────────────┼──────────────────────────────────┤
| 2 | 3 | "Moss and the German" |
└───────────┴────────────┴──────────────────────────────────┘
```

Getting a list of background operations

Using the `ydb operation list` subcommand, you can get a list of background operations of the specified type.

General command format:

```
ydb [global options...] operation list [options...] <kind>
```

- `global options` — global parameters.
- `options` — subcommand parameters.
- `kind` — operation type. Possible values:
  - `analyze` — ANALYZE statistics collection operations
  - `buildindex` — index building operations
  - `compaction` — table compaction operations
  - `export/s3` — export to S3 operations
  - `export/nfs` — export to NFS operations
  - `import/s3` — import from S3 operations
  - `import/nfs` — import from NFS operations
  - `scriptexec` — script execution operations
  - `fullbackup` — full backup operations
  - `incbackup` — incremental backup operations
  - `restore` — restore from a backup collection
  - `setnotnull` — operations for setting the `NOT NULL` constraint.

View the description of the command for getting a list of background operations:

```
ydb operation list --help
```

Subcommand parameters

Name	Description
`-s`, `--page-size`	Number of operations per page. If the operation list contains more rows than specified in the `--page-size` parameter, the output will be split into multiple pages. To get the next page, specify the `--page-token` parameter.
`-t`, `--page-token`	Page token.
`--format`	Output format. Default value — `pretty`. Possible values: • `pretty` — human-readable format • `proto-json-base64` — Protobuf output in JSON format, binary strings are encoded in Base64.

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Get a list of background index building operations for the `series` table:

```
ydb -p quickstart operation list \
  buildindex
```

Result:

```
┌──────────────────────────────────────────┬───────┬─────────┬───────┬──────────┬──────────────────────┬──────────
────┐
| id                                       | ready | status  | state | progress | table                | index
|
├──────────────────────────────────────────┼───────┼─────────┼───────┼──────────┼──────────────────────┼──────────
────┤
| ydb://buildindex/7?id=281489389055514 | true  | SUCCESS | Done  | 100.00%  | /my-database/series | idx_rele
ase |
└──────────────────────────────────────────┴───────┴─────────┴───────┴──────────┴──────────────────────┴──────────
────┘

Next page token: 0
```

Obtaining the status of long-running operations

Use the `ydb operation get` subcommand to obtain the status of the specified long-running operation.

General format of the command:

```
ydb [global options...] operation get [options...] <id>
```

- `global options`: Global parameters.
- `options`: Parameters of the subcommand.
- `id`: The ID of the long-running operation. The ID contains characters that can be interpreted by your command shell. If necessary, use shielding, for example, `'<id>'` for bash.

View a description of the command to obtain the status of a long-running operation:

```
ydb operation get --help
```

Parameters of the subcommand

Name	Description
`--format`	Input format. Default value: `pretty`. Acceptable values: • `pretty`: A human-readable format. • `proto-json-base64`: Protobuf result in JSON format, binary strings are encoded in Base64.

Examples

Note

The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Obtain the status of the long-running operation with the `ydb://buildindex/7?id=281489389055514` ID:

```
ydb -p quickstart operation get \
  'ydb://buildindex/7?id=281489389055514'
```

Result:

```
┌──────────────────────────────────────────┬───────┬──────────┬───────┬──────────┬──────────────────────┬──────────
──┐
| id                                       | ready | status   | state | progress | table                | index
|
├──────────────────────────────────────────┼───────┼──────────┼───────┼──────────┼──────────────────────┼──────────
──┤
| ydb://buildindex/7?id=281489389055514 | true  | SUCCESS | Done  | 100.00%  | /my-database/series | idx_rele
ase |
└──────────────────────────────────────────┴───────┴──────────┴───────┴──────────┴──────────────────────┴──────────
──┘
```

Canceling long-running operations

Use the `ydb operation cancel` subcommand to cancel the specified long-running operation. Only an incomplete operation can be canceled.

General format of the command:

```
ydb [global options...] operation cancel <id>
```

- `global options`: Global parameters.
- `id`: The ID of the long-running operation. The ID contains characters that can be interpreted by your command shell. If necessary, use shielding, for example, `'<id>'` for bash.

View a description of the command to obtain the status of a long-running operation:

```
ydb operation cancel --help
```

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Deleting long running operations from the list

Use the `ydb operation forget` subcommand to delete information about the specified long running operation from the list. The operation must be complete.

General format of the command:

```
ydb [global options...] operation forget <id>
```

- `global options` : Global parameters.
- `id` : The ID of the long running operation. The ID contains characters that can be interpreted by your command shell. If necessary, use shielding, for example, `'<id>'` for bash.

View a description of the command to delete information about the specified long running operation:

```
ydb operation forget --help
```

Examples

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Delete the long running operation with the `ydb://buildindex/7?id=281489389055514` ID from the list:

```
ydb -p db1 operation forget \
  'ydb://buildindex/7?id=281489389055514'
```

Managing profiles

A profile is a named set of DB connection parameters stored in a configuration file in the local file system. With profiles, you can reuse data about DB location and authentication parameters, making a CLI call much shorter:

- Calling the `scheme ls` command without a profile:

```
ydb \
-e grpsc://some.host.in.some.domain:2136 \
-d /some_long_identifier1/some_long_identifier2/database_name \
--yc-token-file ~/secrets/token_database1 \
scheme ls
```

- Calling the same `scheme ls` command using a profile:

```
ydb -p quickstart scheme ls
```

Profile management commands

- Creating a profile
- Using a profile
- Getting a list of profiles and profile parameters
- Deleting a profile
- Activating a profile and using the activated profile

Where profiles are stored

Profiles are stored locally in a file named `~/.ydb/config/config.yaml`.

Creating and updating profiles

You can set connection parameter values for the profile being created or updated through the command line or request them in interactive mode in the console.

Command line

To create or update a profile, the command line uses the `profile create`, `profile update`, and `profile replace` commands.

They only use the values entered directly on the command line without accessing environment variables or the activated profile.

Profile create

`Profile create` creates a new profile with the specified parameter values:

```
ydb config profile create <profile_name> <connection_options>
```

Where:

- `<profile_name>` is the required profile name.
- `<connection options>` are connection parameters to be written to the profile. You need to specify at least one connection parameter; otherwise the command will run in interactive mode.

If a profile with the specified name exists, the command will return an error.

Profile replace

`Profile replace` creates or replaces a profile with the specified parameter values:

```
ydb config profile replace <profile_name> [connection_options]
```

Where:

- `<profile_name>` is the required profile name.
- `<connection options>` are optional connection parameters to be written to the profile.

If a profile with the specified name already exists, it will be overwritten with a new one with the passed-in parameters. If you specify no connection parameters, the profile will be empty once the command completes.

Profile update

`Profile update` modifies the properties of an existing profile:

```
ydb config profile update <profile_name> [connection_options] [reset-options]
```

Where:

- `<profile_name>` is the required profile name.
- `<connection options>` are optional connection parameters to be written to the profile.
- `<reset options>` are optional settings for deleting parameters from an existing profile. Possible values:
  - `--no-endpoint`: Delete an endpoint from the profile
  - `--no-database`: Delete the database path from the profile
  - `--no-auth`: Delete authentication information from the profile
  - `--no-iam-endpoint`: Delete the IAM server URL

The profile will update with the parameters entered on the command line. Any properties not listed on the command line will remain unchanged.

Examples

Creating a profile to connect to a test database

To connect to a DB in a single-node YDB cluster, you can use the `quickstart` profile:

```
ydb config profile create quickstart --endpoint grpc://localhost:2136 --database <path_database>
```

- `path_database`: Database path. Specify one of these values:
  - `/Root/test`: If you used an executable to deploy your cluster.
  - `/local`: If you deployed your cluster from a Docker image.

Creating a profile from previous connection settings

Any command with explicit connection settings performing a YDB database transaction can be converted to a profile create command by moving connection properties from global options to options specific to the `config profile create` command.

For instance, if you successfully ran the `scheme ls` command with the following properties:

```
ydb \
  -e grpcs://example.com:2135 -d /Root/somedatabase --sa-key-file ~/sa_key.json \
  scheme ls
```

You can create a profile to connect to the accessed database using the following command:

```
ydb \
  config profile create db1 \
  -e grpcs://example.com:2135 -d /Root/somedatabase --sa-key-file ~/sa_key.json
```

You can now use much shorter syntax to re-write the original command:

```
ydb -p db1 scheme ls
```

Profile to connect to a local database

Creating/replacing a `local` profile to connect to a local YDB database deployed using quick start:

```
ydb config profile replace local --endpoint grpc://localhost:2136 --database /Root/local
```

Defining the login and password authentication method in the `local` profile:

```
ydb config profile update local --user user1 --password-file ~/pwd.txt
```

Interactive mode

You can use the commands below to create and update profiles in interactive mode:

```
ydb init
```

or

```
ydb config profile create [profile_name] [connection_options]
```

Where:

- `[profile_name]` is an optional name of the profile to create or update.
- `[connection_options]` are optional connection settings to write to the profile.

The `init` command always runs in interactive mode while `config profile create` launches in interactive mode unless you specify a profile name or none of the connection settings on the command line.

The interactive scenario starts differently for the `init` and the `profile create` commands:

Init

1. Prints a list of existing profiles (if any) and prompts you to make a choice: Create a new or update the configuration of an existing profile:

   ```
   Please choose profile to configure:
   [1] Create a new profile
   [2] test
   [3] local
   ```

2. If no profiles exist or you select option `1` in the previous step, the name of a profile to create is requested:

   ```
   Please enter name for a new profile:
   ```

3. If you enter the name of an existing profile at this point, the YDB CLI proceeds to updating its parameters as if an option with the name of this profile was selected at once.

Profile Create

If no profile name is specified on the command line, it is requested:

```
Please enter configuration profile name to create or re-configure:
```

Next, you'll be prompted to sequentially perform the following actions with each connection parameter that can be saved in the profile:

- Don't save
- Set a new value or Use
- Use current value (this option is available when updating an existing profile)

Example

Creating a new `mydb1` profile:

1. Run this command:

   ```
   ydb config profile create mydb1
   ```

2. Enter the endpoint or don't save this parameter for the profile:

```
Pick desired action to configure endpoint:
 [1] Set a new endpoint value
 [2] Don't save endpoint for profile "mydb1"
Please enter your numeric choice:
```

3. Enter the database name or don't save this parameter for the profile:

```
Pick desired action to configure database:
 [1] Set a new database value
 [2] Don't save database for profile "mydb1"
Please enter your numeric choice:
```

4. Select the authentication mode or don't save this parameter for the profile:

```
Pick desired action to configure authentication method:
  [1] Use static credentials (user & password)
  [2] Use IAM token (iam-token) yandex.cloud/docs/iam/concepts/authorization/iam-token
  [3] Use OAuth token of a Yandex Passport user (yc-token). Doesn't work with federative accounts. yande
x.cloud/docs/iam/concepts/authorization/oauth-token
  [4] Use metadata service on a virtual machine (use-metadata-credentials) yandex.cloud/docs/compute/ope
rations/vm-connect/auth-inside-vm
  [5] Use service account key file (sa-key-file) yandex.cloud/docs/iam/operations/iam-token/create-for-s
a
  [6] Set new access token (ydb-token)
  [7] Don't save authentication data for profile "mydb1"
Please enter your numeric choice:
```

   All the available authentication methods are described in Authentication. The set of methods and text of the hints may differ from those given in this example.

   If the method you choose involves specifying an additional parameter, you'll be prompted to enter it. For example, if you select `4` (Use service account key file):

```
Please enter Path to service account key file (sa-key-file):
```

5. In the last step, you'll be prompted to activate the created profile to be used by default. Choose 'n' (No) until you read the article about Activating a profile and using the activated profile:

```
Activate profile "mydb1" to use by default? (current active profile is not set) y/n: n
```

Using a profile

Connection based on a selected profile

A profile can be applied when running a YDB CLI command with the `--profile` or the `-p` option:

```
ydb -p <profile_name> <command and command options>
```

For example:

```
ydb -p mydb1 scheme ls -l
```

In this case, all DB connection parameters are taken from the profile. At the same time, if the authentication parameters are not specified in the profile, the YDB CLI will try to define them based on environment variables, as described in Connecting to and authenticating with a database — Environment variable.

Connection based on a selected profile and specified command line parameters

The `--profile` (`-p`) option doesn't need to be the only connection setting specified on the command line. For example:

```
ydb -p mydb1 -d /local2 scheme ls -l
```

```
ydb -p mydb1 --user alex scheme ls -l
```

In this case, the connection parameters specified on the command line have priority over those stored in the profile. This format lets you reuse profiles to connect to different databases or under different accounts. In addition, specifying the authentication parameter on the command line (such as `--user alex` in the example above) disables environment variable checks regardless of their presence in the profile.

Connection based on an activated profile

If the `--profile` (`-p`) option is not specified on the command line, the YDB CLI will attempt to take all the connection parameters that it couldn't otherwise determine (from the command-line options or environment variables, as described in Connecting to and authenticating with a database) from the currently activated profile.

Implicit use of the activated profile may cause errors, so we recommend that you read the Activated profile article before using this mode.

Getting profile information

Getting a list of profiles

Getting a list of profiles:

```
ydb config profile list
```

If there is a currently activated profile, it will be marked as `(active)` in the output list, for example:

```
prod
test (active)
local
```

Getting detailed profile information

Getting parameters saved in the specified profile:

```
ydb config profile get <profile_name>
```

For example:

```
$ ydb config profile get local1
  endpoint: grpcs://ydb.serverless.yandexcloud.net:2135
  database: /rul1/b1g8skp/etn02099
  sa-key-file: /Users/username/secrets/sa_key_test.json
```

Getting profiles with content

Full information on all profiles and parameters stored in them:

```
ydb config profile list --with-content
```

The output of this command combines the output of the command to get a list of profiles (with the active profile marked) and the parameters of each profile in the lines following its name.

Deleting a profile

Currently, you can only delete profiles interactively with the following command:

```
ydb config profile delete <profile_name>
```

where `<profile_name>` is the profile name.

The YDB CLI will request confirmation to delete the profile:

```
Profile "<profile_name>" will be permanently removed. Continue? (y/n):
```

Choose `y` (Yes) to delete the profile.

Example

Deleting the `mydb1` profile:

```
$ ydb config profile delete mydb1
Profile "mydb1" will be permanently removed. Continue? (y/n): y
Profile "mydb1" was removed.
```

Deleting a profile without interactive input

Although this mode is not supported by the YDB CLI, if necessary, you can use input redirection in your OS to automatically respond `y` to the request to confirm the deletion:

```
echo y | ydb config profile delete my_profile
```

The efficiency of this method is not guaranteed in any way.

Activated profile

Executing YDB CLI commands on a database require establishing a connection to the database. If the YDB CLI couldn't identify a certain connection parameter by command-line parameters and environment variables, it's taken from the activated profile.

Profile activation is an easy way to get started with the YDB CLI, since the connection parameters that are set once will be applied automatically to any command, without the need to specify any connection parameters in the command line.

However, this simplicity may lead to undesirable behavior in further operation, as soon as you need to work with multiple databases:

- The activated profile is applied implicitly, meaning that it can be applied by mistake when a certain connection parameter is missing in the command line.
- The activated profile is applied implicitly, meaning that it can be applied by mistake when a typo is made in the name of an environment variable.
- The activated profile cannot be used in scripts, since it is saved in a file and its change in one terminal window will affect all other windows, possibly leading to an unexpected change of the DB in the middle of the loop being executed in the script.

When you need to connect to any new database other than the initial one for the first time, we recommend that you deactivate the profile and always select it explicitly using the `--profile` option.

Activating a profile with a command

Profile activation is performed by running the command

```
ydb config profile activate [profile_name]
```

where `[profile_name]` is an optional profile name.

If the profile name is specified, it is activated. If a profile with the specified name does not exist, an error is returned prompting you to view the list of available profiles:

```
No existing profile "<profile_name>". Run "ydb config profile list" without arguments to see existing profile
s
```

If the profile name is not specified, you'll be asked to choose between the following options in interactive mode:

```
Please choose profile to activate:
 [1] Don't do anything, just exit
 [2] Deactivate current active profile (if any)
 [3] <profile_name_1> (active)
 [4] <profile_name_2>
 ...
Please enter your numeric choice:
```

- `1` terminates the command execution and keeps the currently activated profile activated. It's marked as `(active)` in the list of existing profiles starting from item 3.
- `2` deactivates the currently activated profile. If no profile has been activated before, nothing changes.
- `3` and so on activates the selected profile. The currently activated profile is marked as `(active)`.

If the profile is successfully activated, the execution ends with a message saying

```
Profile "<profile_name>" was activated.
```

Example

Activating a profile named `mydb1`:

```
$ ydb config profile activate mydb1
Profile "mydb1" was activated.
```

Activating a profile during its initialization

As the last step during the interactive execution of the command to create or update the profile `ydb config profile create`, you're prompted to activate the created (or updated) profile:

```
Activate profile "<profile_name>" to use by default? (current active profile is not set) y/n:
```

Choose `y` (Yes) to activate the profile.

Deactivating a profile

Currently, the YDB CLI only supports profile deactivation in interactive mode, when calling the activation command without specifying the profile (choosing item `2` in the above activation command).

If necessary, you can use input redirection in your OS to automatically select option `2` in interactive input:

```
echo 2 | ydb config profile activate
```

The efficiency of this method is not guaranteed in any way.

List of endpoints

Using the `discovery list` information command, you can get a list of YDB cluster endponts that you can connect to in order to access your database:

```
ydb [connection options] discovery list
```

where [connection options] are database connection options

The output rows in the response contain the following information:

1. Endpoint, including protocol and port
2. Availability zone (in square brackets)
3. The `#` character is used for the list of YDB services available on this endpoint

An endpoint discovery request to the YDB cluster is executed in the YDB SDK at driver initialization so that you can use the `discovery list` CLI command to localize connection issues.

Example

```
$ ydb -p quickstart discovery list
grpcs://vm-etn01q5-ysor.etn01q5k.ydb.mdb.yandexcloud.net:2135 [sas] #table_service #scripting #discovery #rate_limiter #locking #kesus
grpcs://vm-etn01q5-arum.etn01ftr.ydb.mdb.yandexcloud.net:2135 [vla] #table_service #scripting #discovery #rate_limiter #locking #kesus
grpcs://vm-etn01q5beftr.ydb.mdb.yandexcloud.net:2135 [myt] #table_service #scripting #discovery #rate_limiter #locking #kesus
```

Authentication

The `discovery whoami` information command lets you check the account on behalf of which the server actually accepts requests:

```
ydb [connection options] discovery whoami [-g|--groups] [-l|--access-list] [-a|--all]
```

where [connection options] are database connection options

The response includes the account name (User SID). Additional information can be requested using the following options:

- `-g`, `--groups` — Show the groups to which the account belongs
- `-l`, `--access-list` — Show the access levels granted to the account (administration, monitoring, viewer, database, register node, bootstrap)
- `-a`, `--all` — Show all additional information (equivalent to specifying both `-g` and `-l`)

The access levels displayed with the `-l` or `-a` option reflect the hierarchical access control configuration. For detailed information about access level lists and their hierarchy, see Access level lists in the Authorization documentation.

Only access levels that are granted to the user are listed:

- **Database** (presence in `database_allowed_sids`) — Grants the right to access the YDB UI only as "database users": they can open the UI and see database-scoped data, but not cluster-wide data or cluster-level operations.
- **Viewer** (presence in `viewer_allowed_sids`) — Grants the right to access the YDB UI, without the ability to make changes.
- **Monitoring** (presence in `monitoring_allowed_sids`) — Grants the right to perform actions in the YDB UI that change the system state.
- **Administration** (presence in `administration_allowed_sids`) — Grants the right to perform administrative actions on databases or the cluster.
- **Register node** (presence in `register_dynamic_node_allowed_sids`) — Grants the right to register dynamic nodes with the cluster.
- **Bootstrap** (presence in `bootstrap_allowed_sids`) — Grants the right to perform bootstrap operations.

If authentication is not enabled on the YDB server (for example, in the case of an independent local deployment), the command will fail with an error.

Support for the `-g` option depends on the server configuration. If disabled, you'll receive `User has no groups` in response, regardless of the actual inclusion of your account in any groups.

Examples

Basic usage

```
$ ydb -p quickstart discovery whoami
User SID: aje5kkjdgs0puc18976co@as
```

With groups

```
$ ydb -p quickstart discovery whoami -g
User SID: aje5kkjdgs0puc18976co@as

User has no groups
```

With access list

```
$ ydb -p quickstart discovery whoami -l
User SID: user1@builtin

Access levels:
Database
Viewer
```

With all information

```
$ ydb -p quickstart discovery whoami -a
User SID: admin@builtin

Group SIDs:
all-users@well-known
ADMINS

Access levels:
Database
Viewer
Monitoring
Administration
```

Displaying connection parameters

`config info` is a service command for debugging various issues with connection and authentication. The command displays the final connection parameters, such as the endpoint and database path, obtained by considering parameters from all possible sources. With these parameters, the CLI would connect when executing a command that implies a connection to the database. When specifying the global option `-v`, in addition to the final connection parameters, values of all connection parameters from all sources that the CLI managed to detect will be displayed, along with the names of those sources in order of priority

General format of the command:

```
ydb [global options...] config info
```

- `global options` — global parameters.

Connection parameter list

- endpoint — URL of database cluster.
- database — Database path.
- Authentication parameters:
  - token — Access Token.
  - yc-token — Refresh Token.
  - sa-key-file — Service Account Key.
  - use-metadata-credentials — Metadata.
  - user
  - password
- ca-file — Root certificate.
- iam-endpoint — URL of IAM service.

Examples

Display final connection parameters

```
$ ydb -e grpcs://another.endpoint:2135 --ca-file some_certs.crt -p db123 config info
endpoint: another.endpoint:2135
yc-token: SOME_A12****************21_TOKEN
iam-endpoint: iam.api.cloud.yandex.net
ca-file: some_certs.crt
```

Display all connection parameters along with their sources

```
$ ydb -e grpcs://another.endpoint:2135 --ca-file some_certs.crt -p db123 -v config info
Using Yandex.Cloud Passport token from YC_TOKEN env variable

endpoint: another.endpoint:2135
yc-token: SOME_A12****************21_TOKEN
iam-endpoint: iam.api.cloud.yandex.net
ca-file: some_certs.crt
current auth method: yc-token

"ca-file" sources:
  1. Value: some_certs.crt. Got from: explicit --ca-file option

"database" sources:
  1. Value: /some/path. Got from: active profile "test_config_info"

"endpoint" sources:
  1. Value: another.endpoint:2135. Got from: explicit --endpoint option
  2. Value: db123.endpoint:2135. Got from: profile "db123" from explicit --profile option
  3. Value: some.endpoint:2135. Got from: active profile "test_config_info"

"iam-endpoint" sources:
  1. Value: iam.api.cloud.yandex.net. Got from: default value

"sa-key-file" sources:
  1. Value: /Users/username/some-sa-key-file. Got from: active profile "test_config_info"

"yc-token" sources:
  1. Value: SOME_A12****************21_TOKEN. Got from: YC_TOKEN enviroment variable
```

Getting YDB CLI version

Use the `version` subcommand to find out the version of the YDB CLI installed and manage new version availability auto checks.

New version availability auto checks are made when you run any YDB CLI command, except `ydb version --enable-checks` and `ydb version --disable-checks`, but only once in 24 hours. The result and time of the last check are saved to the YDB CLI configuration file.

General format of the command:

```
ydb [global options...] version [options...]
```

- `global options`: Global parameters.
- `options`: Parameters of the subcommand.

View a description of the command:

```
ydb version --help
```

Parameters of the subcommand

Parameter	Description
`--semantic`	Get only the version number.
`--check`	Check if a new version is available.
`--disable-checks`	Disable new version availability checks.
`--enable-checks`	Enable new version availability checks.

Examples

Disable new version availability checks

When running YDB CLI commands, the system automatically checks if a new version is available. If the host where the command is run doesn't have internet access, this causes a delay and the corresponding warning appears during command execution. To disable auto checks for updates, run:

```
ydb version --disable-checks
```

Result:

```
Latest version checks disabled
```

Getting only the version number

To facilitate data handling in scripts, you can limit result to the YDB CLI version number:

```
ydb version --semantic
```

Result:

```
1.9.1
```

Health check

YDB has a built-in self-diagnostic system that provides a brief report on the cluster status and information about existing issues. This report can be obtained via YDB CLI using the command explained below.

General command format:

```
ydb [global options...] monitoring healthcheck [options...]
```

- `global options` — global options,
- `options` — subcommand options.

Subcommand options

Name	Description
`--timeout`	The time, in milliseconds, within which the operation should be completed on the server.
`--format`	Output format. Available options: • `pretty` — overall database status. Possible values are provided in the table. • `json` — a detailed JSON response containing a hierarchical list of detected problems. Possible issues are listed in the Healthcheck API documentation. Default: `pretty`.
`--no-merge`	Do not merge entries of health check result.
`--no-cache`	Do not use cached result.

Examples

Health check result in pretty format

```
ydb --profile quickstart monitoring healthcheck --format pretty
```

Database is in good condition:

```
Healthcheck status: GOOD
```

Database is degraded:

```
Healthcheck status: DEGRADED
```

Health check result in JSON format

```
ydb --profile quickstart monitoring healthcheck --format json
```

Database is in good condition:

```
{
 "self_check_result": "GOOD",
 "location": {
  "id": 51059,
  "host": "my-host.net",
  "port": 19001
 }
}
```

Database is degraded:

```
{
 "self_check_result": "DEGRADED",
 "issue_log": [
  {
   "id": "YELLOW-b3c0-70fb",
   "status": "YELLOW",
   "message": "Database has multiple issues",
   "location": {
    "database": {
     "name": "/my-cluster/my-database"
    }
   },
   "reason": [
    "YELLOW-b3c0-1ba8",
    "YELLOW-b3c0-1c83"
   ],
   "type": "DATABASE",
   "level": 1
  },
  {
   "id": "YELLOW-b3c0-1ba8",
   "status": "YELLOW",
   "message": "Compute is overloaded",
   "location": {

  }
 ],
 "location": {
  "id": 117,
  "host": "my-host.net",
  "port": 19001
 }
}
```

Load testing

You can use the `workload` command to run different types of workload against your DB.

General format of the command:

```
ydb [global options...] workload [subcommands...]
```

- `global options` : Global options.
- `subcommands` : The subcommands.

See the description of the command to run the data load:

```
ydb workload --help
```

Available subcommands

The following types of load tests are supported at the moment:

- Stock: An online store warehouse simulator.
- Key-value: Key-Value load test.
- ClickBench: ClickBench analytical benchmark.
- TPC-C: TPC-C benchmark.
- TPC-H: TPC-H benchmark.
- TPC-DS: TPC-DS benchmark.
- Topic: Topic load test.
- Transfer: Transfer load test.
- Query: Query load test.
- Fulltext: Fulltext load test.
- Vector: Vector search load test.

Global parameters for all workloads

Parameter name	Short name	Parameter description
`--seconds <value>`	`-s <value>`	Duration of the test, in seconds. Default: 10.
`--threads <value>`	`-t <value>`	The number of parallel threads creating the load. Default: 10.
`--rate <value>`	-	Total rate for all threads, in transactions per second. Default: 0 (no rate limit).
`--quiet`	-	Outputs only the total result.
`--print-timestamp`	-	Prints the time together with the statistics of each time window.
`--client-timeout`	-	Transport timeout in milliseconds.
`--operation-timeout`	-	Operation timeout in milliseconds.
`--cancel-after`	-	Timeout for canceling an operation in milliseconds.
`--window`	-	Statistics collection window, in seconds. Default: 1.

Stock load

Simulates a warehouse of an online store: creates multi-product orders, gets a list of orders per customer.

Types of load

This load test runs 5 types of load:

- user-hist: Reads the specified number of orders made by the customer with id = 10000. This creates a workload to read the same rows from different threads.
- rand-user-hist: Reads the specified number of orders made by a randomly selected customer. A load that reads data from different threads is created.
- add-rand-order: Generates an order at random. For example, a customer has created an order of 2 products, but hasn't yet paid for it, hence the quantities in stock aren't decreased for the products. The database writes the data about the order and products. The read/write load is created (the INSERT checks for an existing entry before inserting the data).
- put-rand-order: Generates an order at random and processes it. For example, a customer has created and paid an order of 2 products. The data about the order and products is written to the database, product availability is checked and quantities in stock are decreased. A mixed data load is created.
- put-same-order: Creates orders with the same set of products. For example, all customers buy the same set of products (a newly released phone and a charger). This creates a workload of competing updates of the same rows in the table.

Load test initialization

To get started, create tables and populate them with data:

```
ydb workload stock init [init options...]
```

- `init options`: Initialization options.

See the description of the command to init the data load:

```
ydb workload stock init --help
```

Available parameters

Parameter name	Short name	Parameter description
`--products <value>`	`-p <value>`	Number of products. Valid values: between 1 and 500000. Default: 100.
`--quantity <value>`	`-q <value>`	Quantity of each product in stock. Default: 1000.
`--orders <value>`	`-o <value>`	Initial number of orders in the database. Default: 100.
`--min-partitions <value>`	-	Minimum number of shards for tables. Default: 40.
`--auto-partition <value>`	-	Enabling/disabling auto-sharding. Possible values: 0 or 1. Default: 1.

3 tables are created using the following DDL statements:

```
CREATE TABLE `stock`(product Utf8, quantity Int64, PRIMARY KEY(product)) WITH (AUTO_PARTITIONING_BY_LOAD = EN
ABLED, AUTO_PARTITIONING_MIN_PARTITIONS_COUNT = <min-partitions>);
CREATE TABLE `orders`(id Uint64, customer Utf8, created Datetime, processed Datetime, PRIMARY KEY(id), INDEX
ix_cust GLOBAL ON (customer, created)) WITH (READ_REPLICAS_SETTINGS = "per_az:1", AUTO_PARTITIONING_BY_LOAD =
ENABLED, AUTO_PARTITIONING_MIN_PARTITIONS_COUNT = <min-partitions>, UNIFORM_PARTITIONS = <min-partitions>, AU
TO_PARTITIONING_MAX_PARTITIONS_COUNT = 1000);
CREATE TABLE `orderLines`(id_order Uint64, product Utf8, quantity Int64, PRIMARY KEY(id_order, product)) WITH
(AUTO_PARTITIONING_BY_LOAD = ENABLED, AUTO_PARTITIONING_MIN_PARTITIONS_COUNT = <min-partitions>, UNIFORM_PART
ITIONS = <min-partitions>, AUTO_PARTITIONING_MAX_PARTITIONS_COUNT = 1000);
```

Examples of load initialization

Creating a database with 1000 products, 10000 items of each product, and no orders:

```
ydb workload stock init -p 1000 -q 10000 -o 0
```

Creating a database with 10 products, 100 items of each product, 10 orders, and a minimum number of shards equal 100:

```
ydb workload stock init -p 10 -q 100 -o 10 --min-partitions 100
```

Deleting tables

To delete the tables created during load test initialization, run:

```
ydb [global options...] workload stock clean [options...]
```

Running a load test

To run the load, execute the command:

```
ydb workload stock run [workload type...] [global workload options...] [specific workload options...]
```

During this test, workload statistics for each time window are displayed on the screen.

- `workload type`: The types of workload.
- `global workload options`: Global options for all types of load.
- `specific workload options`: Options of a specific load type.

See the description of the command to run the data load:

```
ydb workload run --help
```

The user-hist workload

This type of load reads the specified number of orders for the customer with id = 10000.

YQL query:

```
DECLARE $cust AS Utf8;
DECLARE $limit AS UInt32;

SELECT id, customer, created FROM orders view ix_cust
    WHERE customer = 'Name10000'
    ORDER BY customer DESC, created DESC
    LIMIT $limit;
```

To run this type of load, execute the command:

```
ydb workload stock run user-hist [global workload options...] [specific workload options...]
```

- `global workload options`: Global options for all types of load.
- `specific workload options`: Options of a specific load type.

Parameters for user-hist

Parameter name	Short name	Parameter description
`--limit <value>`	`-l <value>`	The required number of orders. Default: 10.

The rand-user-hist workload

This type of load reads the specified number of orders from randomly selected customers.

YQL query:

```
DECLARE $cust AS Utf8;
DECLARE $limit AS UInt32;

SELECT id, customer, created FROM orders view ix_cust
    WHERE customer = $cust
    ORDER BY customer DESC, created DESC
    LIMIT $limit;
```

To run this type of load, execute the command:

```
ydb workload stock run rand-user-hist [global workload options...] [specific workload options...]
```

- `global workload options`: Global options for all types of load.
- `specific workload options`: Options of a specific load type.

Parameters for rand-user-hist

Parameter name	Short name	Parameter description
`--limit <value>`	`-l <value>`	The required number of orders. Default: 10.

The add-rand-order workload

This type of load creates a randomly generated order. The order includes several different products, 1 item per product. The number of products in the order is generated randomly based on an exponential distribution.

YQL query:

```
DECLARE $ido AS UInt64;
DECLARE $cust AS Utf8;
DECLARE $lines AS List<Struct<product:Utf8,quantity:Int64>>;
DECLARE $time AS DateTime;

INSERT INTO `orders`(id, customer, created) VALUES
    ($ido, $cust, $time);
UPSERT INTO `orderLines`(id_order, product, quantity)
    SELECT $ido, product, quantity FROM AS_TABLE( $lines );
```

To run this type of load, execute the command:

```
ydb workload stock run add-rand-order [global workload options...] [specific workload options...]
```

- `global workload options`: Global options for all types of load.
- `specific workload options`: Options of a specific load type.

Parameters for add-rand-order

Parameter name	Short name	Parameter description
`--products <value>`	`-p <value>`	Number of products in the test. Default: 100.

The put-rand-order workload

This type of load creates a randomly generated order and processes it. The order includes several different products, 1 item per product. The number of products in the order is generated randomly based on an exponential distribution. Order processing consists in decreasing the number of ordered products in stock.

YQL query:

```
DECLARE $ido AS UInt64;
DECLARE $cust AS Utf8;
DECLARE $lines AS List<Struct<product:Utf8,quantity:Int64>>;
DECLARE $time AS DateTime;

INSERT INTO `orders`(id, customer, created) VALUES
    ($ido, $cust, $time);

UPSERT INTO `orderLines`(id_order, product, quantity)
    SELECT $ido, product, quantity FROM AS_TABLE( $lines );

$prods = SELECT * FROM orderLines AS p WHERE p.id_order = $ido;

$cnt = SELECT COUNT(*) FROM $prods;

$newq =
    SELECT
        p.product AS product,
        COALESCE(s.quantity, 0) - p.quantity AS quantity
    FROM $prods AS p
    LEFT JOIN stock AS s
    ON s.product = p.product;

$check = SELECT COUNT(*) AS cntd FROM $newq as q WHERE q.quantity >= 0;

UPSERT INTO stock
    SELECT product, quantity FROM $newq WHERE $check=$cnt;

$upo = SELECT id, $time AS tm FROM orders WHERE id = $ido AND $check = $cnt;

UPSERT INTO orders SELECT id, tm AS processed FROM $upo;

SELECT * FROM $newq AS q WHERE q.quantity < 0
```

To run this type of load, execute the command:

```
ydb workload stock run put-rand-order [global workload options...] [specific workload options...]
```

- `global workload options`: Global options for all types of load.
- `specific workload options`: Options of a specific load type.

Parameters for put-rand-order

Parameter name	Short name	Parameter description
`--products <value>`	`-p <value>`	Number of products in the test. Default: 100.

The put-same-order workload

This type of load creates an order with the same set of products and processes it. Order processing consists in decreasing the number of ordered products in stock.

YQL query:

```
DECLARE $ido AS UInt64;
DECLARE $cust AS Utf8;
DECLARE $lines AS List<Struct<product:Utf8,quantity:Int64>>;
DECLARE $time AS DateTime;

INSERT INTO `orders`(id, customer, created) VALUES
    ($ido, $cust, $time);

UPSERT INTO `orderLines`(id_order, product, quantity)
    SELECT $ido, product, quantity FROM AS_TABLE( $lines );

$prods = SELECT * FROM orderLines AS p WHERE p.id_order = $ido;

$cnt = SELECT COUNT(*) FROM $prods;

$newq =
    SELECT
        p.product AS product,
        COALESCE(s.quantity, 0) - p.quantity AS quantity
    FROM $prods AS p
    LEFT JOIN stock AS s
    ON s.product = p.product;

$check = SELECT COUNT(*) AS cntd FROM $newq as q WHERE q.quantity >= 0;

UPSERT INTO stock
    SELECT product, quantity FROM $newq WHERE $check=$cnt;

$upo = SELECT id, $time AS tm FROM orders WHERE id = $ido AND $check = $cnt;

UPSERT INTO orders SELECT id, tm AS processed FROM $upo;

SELECT * FROM $newq AS q WHERE q.quantity < 0
```

To run this type of load, execute the command:

```
ydb workload stock run put-same-order [global workload options...] [specific workload options...]
```

- `global workload options`: Global options for all types of load.
- `specific workload options`: Options of a specific load type.

Parameters for put-same-order

Parameter name	Short name	Parameter description
`--products <value>`	`-p <value>`	Number of products per order. Default: 100.

Examples of running the loads

- Run the `add-rand-order` workload for 5 seconds across 10 threads with 1000 products.

```
ydb workload stock run add-rand-order -s 5 -t 10 -p 1000
```

Possible result:

```
Elapsed Txs/Sec Retries Errors  p50(ms) p95(ms) p99(ms) pMax(ms)
1           132 0       0       69      108     132     157
2           157 0       0       63      88      97      104
3           156 0       0       62      84      104     120
4           160 0       0       62      77      90      94
5           174 0       0       61      77      97      100

Txs     Txs/Sec Retries Errors  p50(ms) p95(ms) p99(ms) pMax(ms)
779       155.8 0       0       62      89      108     157
```

- Run the `put-same-order` workload for 5 seconds across 5 threads with 2 products per order, printing out only final results.

```
ydb workload stock run put-same-order -s 5 -t 5 -p 1000 --quiet
```

Possible result:

```
Txs     Txs/Sec Retries Errors  p50(ms) p95(ms) p99(ms) pMax(ms)
16          3.2 67      3       855     1407    1799    1799
```

- Run the `rand-user-hist` workload for 5 seconds across 100 threads, printing out time for each time window.

```
ydb workload stock run rand-user-hist -s 5 -t 10 --print-timestamp
```

Possible result:

```
Elapsed Txs/Sec Retries Errors  p50(ms) p95(ms) p99(ms) pMax(ms)        Timestamp
1          1046 0       0       7       16      25      50      2022-02-08T17:47:26Z
2          1070 0       0       7       17      22      28      2022-02-08T17:47:27Z

Txs     Txs/Sec Retries Errors  p50(ms) p95(ms) p99(ms) pMax(ms)
5200       1040 0       0       8       17      23      50
```

Interpretation of results

- `Elapsed`: Time window ID. By default, a time window is 1 second.
- `Txs/sec`: Number of successful load transactions in the time window.
- `Retries`: The number of repeat attempts to execute the transaction by the client in the time window.
- `Errors`: The number of errors that occurred in the time window.
- `p50(ms)`: 50th percentile of request latency, in ms.
- `p95(ms)`: 95th percentile of request latency, in ms.
- `p99(ms)`: 99th percentile of request latency, in ms.
- `pMax(ms)`: 100th percentile of request latency, in ms.
- `Timestamp`: Timestamp of the end of the time window.

ClickBench load

The load is based on data and queries from the https://github.com/ClickHouse/ClickBench repository, and the queries and table layout are adapted to YDB.

The benchmark generates typical workload in the following areas: clickstream and traffic analysis, web analytics, machine-generated data, structured logs, and event data. It covers typical queries in analytics and real-time dashboards.

The dataset for this benchmark was obtained from an actual traffic recording of one of the world's largest web analytics platforms. It has been anonymized while keeping all the essential data distributions. The query set was improvised to reflect realistic workloads, while the queries are not directly from production.

Common command options

All commands support the common option `--path`, which specifies the path to a table in the database:

```
ydb workload clickbench --path clickbench/hits ...
```

Available options

Name	Description	Default value
`--path` or `-p`	Specifies the table path.	`clickbench/hits`

Initializing a load test

Before running the benchmark, create a table:

```
ydb workload clickbench --path clickbench/hits init
```

See the description of the command to init the data load:

```
ydb workload clickbench init --help
```

Available parameters

Name	Description	Default value
`--store <value>`	Table storage type. Possible values: `row`, `column`, `external-s3`.	`column`.
`--external-s3-prefix <value>`	Only relevant for external tables. Root path to the dataset in S3 storage.	
`--external-s3-endpoint <value>` or `-e <value>`	Only relevant for external tables. Link to S3 Bucket with data.	
`--string`	Use `String` type for text fields. `Utf8` is used by default.	
`--datetime`	Use `Date`, `Datetime` and `Timestamp` type for time-related fields.	`Date32`, `Datetime64` and `Timestamp64`
`--partition-size`	Maximum partition size in megabytes (AUTO_PARTITIONING_PARTITION_SIZE_MB) for row tables.	2000
`--clear`	If the table at the specified path has already been created, it will be deleted.	
`--dry-run`	Do not execute initialization queries, but only display their text.	

Loading data into a table

Download the data archive, then load the data into the table:

```
wget https://datasets.clickhouse.com/hits_compatible/hits.csv.gz
ydb workload clickbench --path clickbench/hits import files --input hits.csv.gz
```

For source files, you can use CSV and TSV files, as well as directories containing such files. They can be either compressed or not.

Available parameters

Name	Description	Default value
`--input <path>` or `-i <path>`	Path to the source data files. Both unpacked and packed CSV and TSV files, as well as directories containing such files, are supported. Data can be downloaded from the official ClickBench website: csv.gz, tsv.gz. To speed up the process, these files can be split into smaller parts, allowing parallel downloads.	
`--state <path>`	Path to the download state file. If the download is interrupted, it will resume from the same point when restarted.	
`--clear-state`	Relevant if the `--state` parameter is specified. Clears the state file and restarts the download from the beginning.	

`--dry-run`	Do not execute loading queries, but only display their text.	

Common parameters of the import command

Name	Description	Default value
`--upload-threads <value>` or `-t <value>`	The number of execution threads for data preparation.	The number of available cores on the client.
`--bulk-size <value>`	The size of the chunk for sending data, in rows.	10000
`--max-in-flight <value>`	The maximum number of data chunks that can be processed simultaneously.	128
`--file-output-path <value>` or `-f <path>`	If this option is set, the data will not be loaded into the database, but will be saved to the directory .	

Run a load test

Run the load:

```
ydb workload clickbench --path clickbench/hits run
```

During the test, load statistics are displayed for each request.

See the command description to run the load:

```
ydb workload clickbench run --help
```

Common parameters for all load types

Name	Description	Default value
`--dry-run`	Do not execute initialization queries, but only display their text.	
`--check-canonical` or `-c`	Use special version of queries (they have deterministic answers) and compare results with canonical ones.	
`--output <value>`	The name of the file where the query execution results will be saved.	`results.out`
`--iterations <value>`	The number of times each load query will be executed.	`1`
`--json <name>`	The name of the file where query execution statistics will be saved in `json` format.	Not saved by default
`--ministat <name>`	The name of the file where query execution statistics will be saved in `ministat` format.	Not saved by default
`--csv <name>`	The name of the file to save the CSV version of the result table.	Not saved by default
`--plan <name>`	The name of the file to save the query plan. Files like `<name>.<query number>.explain` and `<name>.<query number>.<iteration number>` will be saved in formats: `ast`, `json`, `svg`, and `table`.	Not saved by default
`--query-prefix <setting>`	Query prefix. Every prefix is a line that will be added to the beginning of each query. For multiple prefix lines use this option several times.	Not specified by default
`--retries`	Max retry count for every request.	`0`
`--include`	Names, numbers or ranges of query numbers to be executed as part of the load. Specified as a comma-separated list, e.g.: `1,2,4-6`.	All queries executed
`--exclude`	Names, numbers or ranges of query numbers to be excluded from the load. Specified as a comma-separated list, e.g.: `1,2,4-6`.	None excluded by default
`--verbose` or `-v`	Print additional information to the screen during query execution.	
`--global-timeout <value>`	Global timeout for all queries. Supports time units (e.g., '5s', '1m'). Plain number interpreted as milliseconds.	Not specified by default. The time is unlimited.
`--request-timeout <value>`	Timeout for each iteration of each query. Supports time units (e.g., '5s', '1m'). Plain number interpreted as milliseconds.	Not specified by default. The time is unlimited.
`--threads <value>` or `-t <value>`	The number of parallel threads generating the load. Zero means that queries will be executed in the main thread; otherwise, queries will be mixed.	`0`
`--stats <value>`	Extended execution statistics collection mode. Available values: `full`, `profile`.	`full`

ClickBench-specific options

Name	Description	Default value

`--syntax <value>`	Syntax of the queries to use. Available values: `yql`. For more information about working with YQL syntax, see here.	`yql`

Cleanup test data

Run cleanup:

```
ydb workload clickbench --path clickbench/hits clean
```

The command has no parameters.

Key-Value load

A simple load type using a YDB database as a Key-Value storage.

Types of load

This load test runs several types of load:

- upsert: Using the UPSERT operation, inserts rows that are tuples (key1, key2, ... keyK, value1, value2, ... valueN) into the table created previously with the init command, the K and N numbers are specified in the settings.
- insert: The function is the same as the upsert load, only the INSERT operation is used for insertion.
- select: Reads data using the SELECT * WHERE key = $key operation. A query always affects all table columns, but isn't always a point query, and the number of primary key variations can be controlled using parameters.
- read-rows: Reads data using the ReadRows operation, which performs faster key reading than select operation. A query always affects all table columns, but isn't always a point query, and the number of primary key variations can be controlled using parameters.
- mixed: Simultaneously writes and reads data, additionally checking that all written data is successfully read.

Load test initialization

To get started, you must create tables. When creating them, you can specify how many rows to insert during initialization:

```
ydb workload kv init [init options...]
```

- `init options` : Initialization options.

View a description of the command to initialize the table:

```
ydb workload kv init --help
```

Available parameters

Parameter name	Parameter description
`--init-upserts <value>`	Number of insertion operations to be performed during initialization. Default: 1000.
`--min-partitions`	Minimum number of shards for tables. Default: 40.
`--partition-size`	Maximum size of one shard (the `AUTO_PARTITIONING_PARTITION_SIZE_MB` setting). Default: 2000.
`--auto-partition`	Enabling/disabling auto-sharding. Possible values: 0 or 1. Default: 1.
`--max-first-key`	Maximum value of the primary key of the table. Default: .
`--len`	The size of the rows in bytes that are inserted into the table as values. Default: 8.
`--cols`	Number of columns in the table. Default: 2 counting Key.
`--int-cols`	Number of first columns in the table that will have the `Uint64` type; subsequent columns will have the `String` type. Default: 1.
`--key-cols`	Number of first columns in the table included in the key. Default: 1.
`--rows`	Number of affected rows in one query. Default: 1.

The following command is used to create a table:

```
CREATE TABLE `kv_test`(
    c0 Uint64,
    c1 Uint64,
    ...
    cI Uint64,
    cI+1 String,
    ...
    cN String,
    PRIMARY KEY(c0, c1, ... cK)) WITH (
        AUTO_PARTITIONING_BY_LOAD = ENABLED,
        AUTO_PARTITIONING_MIN_PARTITIONS_COUNT = partsNum,
        UNIFORM_PARTITIONS = partsNum,
        AUTO_PARTITIONING_PARTITION_SIZE_MB = partSize,
        AUTO_PARTITIONING_MAX_PARTITIONS_COUNT = 1000
    )
)
```

Examples of load initialization

Example of a command to create a table with 1000 rows:

```
ydb workload kv init --init-upserts 1000
```

Deleting a table

When the work is complete, you can delete the table:

```
ydb workload kv clean
```

The following YQL command is executed:

```
DROP TABLE `kv_test`
```

Examples of using clean

```
ydb workload kv clean
```

Running a load test

To run the load, execute the command:

```
ydb workload kv run [workload type...] [global workload options...] [specific workload options...]
```

During this test, workload statistics for each time window are displayed on the screen.

- `workload type`: The types of workload.
- `global workload options`: The global options for all types of load.
- `specific workload options`: Options of a specific load type.

See the description of the command to run the data load:

```
ydb workload kv run --help
```

Global parameters for all types of load

Parameter name	Short name	Parameter description
`--seconds <value>`	`-s <value>`	Duration of the test, in seconds. Default: 10.
`--threads <value>`	`-t <value>`	The number of parallel threads creating the load. Default: 10.
`--rate <value>`	-	Total rate for all threads, in requests per second. Default: 0 (no rate limit).
`--quiet`	-	Outputs only the total result.
`--print-timestamp`	-	Print the time together with the statistics of each time window.
`--client-timeout`	-	Transport timeout in milliseconds.
`--operation-timeout`	-	Operation timeout in milliseconds.
`--cancel-after`	-	Timeout for canceling an operation in milliseconds.
`--window`	-	Statistics collection window in seconds. Default: 1.
`--max-first-key`	-	Maximum value of the primary key of the table. Default: .
`--cols`	-	Number of columns in the table. Default: 2 counting Key.
`--int-cols`	-	Number of first columns in the table that will have the `Uint64` type; subsequent columns will have the `String` type. Default: 1.
`--key-cols`	-	Number of first columns in the table included in the key. Default: 1.
`--rows`	-	Number of affected rows in one query. Default: 1.

Upsert load

This load type inserts tuples (key, value1, value2, ..., valueN)

To run this type of load, execute the command:

```
ydb workload kv run upsert [global workload options...] [specific workload options...]
```

- `global workload options`: The global options for all types of load.
- `specific workload options`: Options of a specific load type.

For example, for the parameters `--rows 2 --cols 3 --int-cols 2`, the YQL query will look like this:

```
DECLARE $c0_0 AS Uint64;
DECLARE $c0_1 AS Uint64;
DECLARE $c0_2 AS String;
DECLARE $c1_0 AS Uint64;
DECLARE $c1_1 AS Uint64;
DECLARE $c1_2 AS String;
UPSERT INTO `kv_test` (c0, c1, c2) VALUES ($c0_0, $c0_1, $c0_2), ($c1_0, $c1_1, $c1_2)
```

Parameters for upsert

Parameter name	Parameter description
`--len`	The size of the rows in bytes that are inserted into the table as values. Default: 8.

Insert load

This load type inserts tuples (key, value1, value2, ..., valueN)

To run this type of load, execute the command:

```
ydb workload kv run insert [global workload options...] [specific workload options...]
```

- `global workload options` : The global options for all types of load.
- `specific workload options` : Options of a specific load type.

For example, for the parameters `--rows 2 --cols 3 --int-cols 2`, the YQL query will look like this:

```
DECLARE $c0_0 AS Uint64;
DECLARE $c0_1 AS Uint64;
DECLARE $c0_2 AS String;
DECLARE $c1_0 AS Uint64;
DECLARE $c1_1 AS Uint64;
DECLARE $c1_2 AS String;
INSERT INTO `kv_test` (c0, c1, c2) VALUES ($c0_0, $c0_1, $c0_2), ($c1_0, $c1_1, $c1_2)
```

Parameters for insert

Parameter name	Parameter description
`--len`	The size of the rows in bytes that are inserted into the table as values. Default: 8.

Select load

This type of load creates SELECT queries that return rows based on an exact match of the primary key.

To run this type of load, execute the command:

```
ydb workload kv run select [global workload options...]
```

- `global workload options` : The global options for all types of load.

For example, for the parameters `--rows 2 --cols 3 --int-cols 2`, the YQL query will look like this:

```
DECLARE $r0_0 AS Uint64;
DECLARE $r0_1 AS Uint64;
DECLARE $r1_0 AS Uint64;
DECLARE $r1_1 AS Uint64;
SELECT c0, c1, c2 FROM `kv_test` WHERE c0 = $r0_0 AND c1 = $r0_1 OR c0 = $r1_0 AND c1 = $r1_1
```

Read-rows load

This type of load creates ReadRows queries that return rows based on an exact match of the primary key.

To run this type of load, execute the command:

```
ydb workload kv run read-rows [global workload options...]
```

- `global workload options` : The global options for all types of load.

Mixed load

This type of load simultaneously writes and reads tuples (key, value1, value2, ..., valueN), additionally checking that all written data is successfully read.

To run this type of load, execute the command:

```
ydb workload kv run mixed [global workload options...] [specific workload options...]
```

- `global workload options` : The global options for all types of load.
- `specific workload options` - Options of a specific load type.

Parameters for mixed

Parameter name	Parameter description
`--len`	The size of the rows in bytes that are inserted into the table as values. Default: 8.
`--change-partitions-size`	Enabling/disabling random modification of the `AUTO_PARTITIONING_PARTITION_SIZE_MB` setting. Possible values: 0 or 1. Default: 0.
`--do-select`	Enabling/disabling reads using the select query. Possible values: 0 or 1. Default: 1.
`--do-read-rows`	Enabling/disabling reads using the read-rows query. Possible values: 0 or 1. Default: 1.

Topic load

Applies load to your YDB topics, using them as message queues. You can use a variety of input parameters to simulate production load: message number, message size, target write rate, and number of consumers and producers.

As you apply load to your topic, the console displays the results (the number of written messages, message write rate, and others).

To generate load against your topic:

1. Initialize the load.
2. Run one of the available load types:
   - write: Generate messages and write them to the topic asynchronously.
   - read: Read messages from the topic asynchronously.
   - full: Read and write messages asynchronously in parallel.

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Initializing a load test

Before executing the load, you need to initialize it. During initialization, you will create a topic named `workload-topic` with the specified options. To initialize the load, run the following command:

```
ydb [global options...] workload topic init [options...]
```

- `global options`: Global options.
- `options`: Subcommand options.

Subcommand options:

Option name	Option description
`--topic`	Topic name. Default value: `workload-topic`.
`--partitions`, `-p`	Number of topic partitions. Default value: `128`.
`--consumers`, `-c`	Number of topic consumers. Default value: `1`.
`--consumer-prefix`	Consumer name prefix. Default value: `workload-consumer`. For example, if the number of consumers `--consumers` is `2` and the prefix `--consumer-prefix` is `workload-consumer`, then the following consumer names will be used: `workload-consumer-0`, `workload-consumer-1`.

To create a topic with `256` partitions and `2` consumers, run this command:

```
ydb --profile quickstart workload topic init --partitions 256 --consumers 2
```

Write load

This load type generates and writes messages to the topic asynchronously.

General format of the command that generates the write load:

```
ydb [global options...] workload topic run write [options...]
```

- `global options`: Global options.
- `options`: Subcommand options.

View the description of the command that generates the write load:

```
ydb workload topic run write --help
```

Subcommand options:

Option name	Option description
`--seconds`, `-s`	Test duration in seconds. Default value: `60`.
`--window`, `-w`	Statistics window in seconds. Default value: `1`.
`--quiet`, `-q`	Output only the final test result.
`--print-timestamp`	Print the time together with the statistics of each time window.

`--warmup`	Test warm-up period (in seconds). Within the period, no statistics are calculated. It's needed to eliminate the effect of transition processes at startup. Default value: `5`.
`--percentile`	Percentile that is output in statistics. Default value: `50`.
`--topic`	Topic name. Default value: `workload-topic`.
`--threads`, `-t`	Number of producer threads. Each thread will write to all partitions of the specified topic. Default value: `1`.
`--message-size`, `-m`	Message size in bytes. Use the `K`, `M`, or `G` suffix to set the size in KB, MB, or GB, respectively. Default value: `10K`.
`--message-rate`	Total target write rate in messages per second. Can't be used together with the `--byte-rate` option. Default value: `0` (no limit).
`--byte-rate`	Total target write rate in bytes per second. Can't be used together with the `--message-rate` option. Use the `K`, `M`, or `G` suffix to set the rate in KB/s, MB/s, or GB/s, respectively. Default value: `0` (no limit).
`--codec`	Codec used to compress messages on the client before sending them to the server. Compression increases CPU usage on the client when reading and writing messages, but usually enables you to reduce the amounts of data stored and transmitted over the network. When consumers read messages, they decompress them by the codec that was used to write the messages, with no special options needed. Acceptable values: `RAW` - no compression (default), `GZIP`, `ZSTD`.
`--use-tx`	Use transactions. Disabled by default.
`--tx-commit-interval`	Transaction commit interval, in milliseconds. A transaction is committed if the time specified in the `--tx-commit-interval` parameter elapses or if the number of messages specified in the `--tx-commit-messages` parameter is written. Default value: `1000`.
`--tx-commit-messages`	Number of messages required to commit a transaction. A transaction is committed if the time specified in the `--tx-commit-interval` parameter elapses or if the number of messages specified in the `--tx-commit-messages` parameter is written. Default value: `1 000 000`.

To write data to `100` producer threads at the target rate of `80` MB/s for `10` seconds, run this command:

```
ydb --profile quickstart workload topic run write --threads 100 --byte-rate 80M
```

You will see statistics for in-progress time windows and final statistics when the test is complete:

```
Window  Write speed     Write time      Inflight
#       msg/s   MB/s    percentile,ms   percentile,msg
1       20      0       1079            72
2       8025    78      1415            78
3       7987    78      1431            79
4       7888    77      1471            101
5       8126    79      1815            116
6       7018    68      1447            79
7       8938    87      2511            159
8       7055    68      1463            78
9       7062    69      1455            79
10      9912    96      3679            250
Window  Write speed     Write time      Inflight
#       msg/s   MB/s    percentile,ms   percentile,msg
Total   7203    70      3023            250
```

- `Window`: Sequence number of the statistics window.
- `Write speed`: Message write rate in messages per second and MB/s.
- `Write time`: Percentile of the message write time, in milliseconds.
- `Inflight`: Maximum number of messages awaiting commit across all partitions.

If you enable transactions, the command output will also include the `Commit time` column. It displays the percentile of transaction commit time, in milliseconds.

Read load

This type of load reads messages from the topic asynchronously. To make sure that the topic includes messages, run the write load before you start reading.

General format of the command to generate the read load:

```
ydb [global options...] workload topic run read [options...]
```

- `global options`: Global options.
- `options`: Subcommand options.

View the description of the command to generate the read load:

```
ydb workload topic run read --help
```

Subcommand options:

Option name	Option description
`--seconds`, `-s`	Test duration in seconds. Default value: `60`.
`--window`, `-w`	Statistics window in seconds. Default value: `1`.
`--quiet`, `-q`	Output only the final test result.
`--print-timestamp`	Print the time together with the statistics of each time window.
`--warmup`	Test warm-up period (in seconds). Within the period, no statistics are calculated. It's needed to eliminate the effect of transition processes at startup. Default value: `5`.
`--percentile`	Percentile that is output in statistics. Default value: `50`.
`--topic`	Topic name. Default value: `workload-topic`.
`--consumers`, `-c`	Number of consumers. Default value: `1`.
`--consumer-prefix`	Consumer name prefix. Default value: `workload-consumer`. For example, if the number of consumers `--consumers` is `2` and the prefix `--consumer-prefix` is `workload-consumer`, then the following consumer names will be used: `workload-consumer-0`, `workload-consumer-1`.
`--threads`, `-t`	Number of consumer threads. Default value: `1`.

To use `2` consumers to read data from the topic, with `100` threads per consumer, run the following command:

```
ydb --profile quickstart workload topic run read --consumers 2 --threads 100
```

You will see statistics for in-progress time windows and final statistics when the test is complete:

```
Window  Lag             Lag time        Read speed      Full time
#       percentile,msg  percentile,ms   msg/s   MB/s    percentile,ms
1       0               0               0       0       0
2       30176           0               66578   650     0
3       30176           0               68999   674     0
4       30176           0               66907   653     0
5       27835           0               67628   661     0
6       30176           0               67938   664     0

9       30176           0               61770   603     0
10      30176           0               58291   569     0
Window  Lag             Lag time        Read speed      Full time
#       percentile,msg  percentile,ms   msg/s   MB/s    percentile,ms
Total   30176           0               80267   784     0
```

- `Window`: Sequence number of the statistics window.
- `Lag`: Maximum consumer lag in the statistics window. Messages across all partitions are included.
- `Lag time`: Percentile of the message lag time in milliseconds.
- `Read`: Message read rate for the consumer (in messages per second and MB/s).
- `Full time`: Percentile of the full message processing time (from writing by the producer to reading by the consumer), in milliseconds.

Read and write load

This type of load both reads messages from the topic and writes them to the topic asynchronously. This command is equivalent to running both read and write loads in parallel.

General format of the command to generate the read and write load:

```
ydb [global options...] workload topic run full [options...]
```

- `global options`: Global options.
- `options`: Subcommand options.

View the description of the command to run the read and write load:

```
ydb workload topic run full --help
```

Subcommand options:

Option name	Option description
`--seconds`, `-s`	Test duration in seconds. Default value: `60`.
`--window`, `-w`	Statistics window in seconds. Default value: `1`.
`--quiet`, `-q`	Output only the final test result.
`--print-timestamp`	Print the time together with the statistics of each time window.
`--warmup`	Test warm-up period (in seconds). Within the period, no statistics are calculated. It's needed to eliminate the effect of transition processes at startup. Default value: `5`.
`--percentile`	Percentile that is output in statistics. Default value: `50`.
`--topic`	Topic name. Default value: `workload-topic`.
`--producer-threads`, `-p`	Number of producer threads. Each thread will write to all partitions of the specified topic. Default value: `1`.
`--message-size`, `-m`	Message size in bytes. Use the `K`, `M`, or `G` suffix to set the size in KB, MB, or GB, respectively. Default value: `10K`.
`--message-rate`	Total target write rate in messages per second. Can't be used together with the `--message-rate` option. Default value: `0` (no limit).
`--byte-rate`	Total target write rate in bytes per second. Can't be used together with the `--byte-rate` option. Use the `K`, `M`, or `G` suffix to set the rate in KB/s, MB/s, or GB/s, respectively. Default value: `0` (no limit).
`--codec`	Codec used to compress messages on the client before sending them to the server. Compression increases CPU usage on the client when reading and writing messages, but usually enables you to reduce the amounts of data stored and transmitted over the network. When consumers read messages, they decompress them by the codec that was used to write the messages, with no special options needed. Acceptable values: `RAW` - no compression (default), `GZIP`, `ZSTD`.
`--consumers`, `-c`	Number of consumers. Default value: `1`.
`--consumer-prefix`	Consumer name prefix. Default value: `workload-consumer`. For example, if the number of consumers `--consumers` is `2` and the prefix `--consumer-prefix` is `workload-consumer`, then the following consumer names will be used: `workload-consumer-0`, `workload-consumer-1`.
`--threads`, `-t`	Number of consumer threads. Default value: `1`.
`--use-tx`	Use transactions. Disabled by default.
`--tx-commit-interval`	Transaction commit interval, in milliseconds. A transaction is committed if the time specified in the `--tx-commit-interval` parameter elapses or if the number of messages specified in the `--tx-commit-messages` parameter is written. Default value: `1000`.
`--tx-commit-messages`	Number of messages required to commit a transaction. A transaction is committed if the time specified in the `--tx-commit-interval` parameter elapses or if the number of messages specified in the `--tx-commit-messages` parameter is written. Default value: `1 000 000`.

Example of a command that reads `50` threads by `2` consumers and writes data to `100` producer threads at the target rate of `80` MB/s and duration of `10` seconds:

```
ydb --profile quickstart workload topic run full --producer-threads 100 --consumers 2 --consumer-threads 50 --byte-rate 80M
```

You will see statistics for in-progress time windows and final statistics when the test is complete:

```
Window  Write speed     Write time      Inflight        Lag             Lag time        Read speed      Full
time
#       msg/s   MB/s    percentile,ms   percentile,msg  percentile,msg  percentile,ms   msg/s   MB/s    perce
ntile,ms
1       0       0       0               0               0               0               0       0       0
2       1091    10      2143            8               2076            20607           40156   392     30941
3       1552    15      2991            12              7224            21887           41040   401     31886

9       1952    19      2543            10              7627            27391           33284   325     37814
10      1992    19      2655            9               10104           28671           29101   284     38797
Window  Write speed     Write time      Inflight        Lag             Lag time        Read speed      Full
time
#       msg/s   MB/s    percentile,ms   percentile,msg  percentile,msg  percentile,ms   msg/s   MB/s    perce
ntile,ms
Total   1814    17      5247            22              12150           28671           44827   438     40252
```

- `Window`: Sequence number of the statistics window.
- `Write speed`: Message write rate in messages per second and MB/s.
- `Write time`: Percentile of the message write time, in milliseconds.
- `Inflight`: Maximum number of messages awaiting commit across all partitions.
- `Lag`: Maximum number of messages awaiting reading, in the statistics window. Messages across all partitions are included.
- `Lag time`: Percentile of the message lag time in milliseconds.
- `Read`: Message read rate for the consumer (in messages per second and MB/s).
- `Full time`: Percentile of the full message processing time, from writing by the producer to reading by the consumer, in milliseconds.

Deleting a topic

When the work is complete, you can delete the test topic: General format of the topic deletion command:

```
ydb [global options...] workload topic clean [options...]
```

- `global options`: Global options.
- `options`: Subcommand options.

Subcommand options:

Option name	Option description
`--topic`	Topic name. Default value: `workload-topic`.

To delete the `workload-topic` test topic, run the following command:

```
ydb --profile quickstart workload topic clean
```

Transfer load

Starts the load in the form of transactions YDB involving topics and tables simultaneously. The data is read from the topic and written to the table. To simulate a real load, you can set various input parameters: the number of messages, the size of messages, the target write speed, the number of consumers and producers, the number of partitions. During operation, the console displays the results: the number of written messages, the speed of writing messages, etc.

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Initializing the test environment

Before starting the load, it is necessary to initialize the test environment. You can use the command `ydb workload transfer topic-to-table init` to do this. It will create a topic and a table with the necessary parameters.

Command syntax:

```
ydb [global options...] workload transfer topic-to-table init [options...]
```

- `global options` — global parameters.
- `options` - parameters of the subcommand.

View the command description:

```
ydb workload transfer topic-to-table init --help
```

Parameters of the subcommand:

Parameter name	Parameter description	Default value
`--topic`	Topic name	`transfer-topic`
`--consumer-prefix`	Prefix of the consumers name	`workload-consumer`
`--table`	Table name	`transfer-table`
`--consumers`	Number of topic consumers	`1`
`--topic-partitions`	Number of topic partitions	`128`
`--table-partitions`	Number of table partitions	`128`

After executing the `init` subcommand, a table, topic and consumers will be created. Reader names are created by the rule `${CONSUMER_PREFIX}-${INDEX}`. The value of `${INDEX}` is an integer from 0 to the value of the parameter `--consumers` minus 1.

For example, the command `ydb --profile quickstart workload transfer topic-to-table init --consumers 2 --topic-partitions 143 --table-partitions 237` will create a topic `transfer-topic` with 2 consumers, 143 partitions, and a table `transfer-table` with 237 partitions. The consumer names are `workload-consumer-0` and `workload-consumer-1`.

Running a load test

The test simulates the load from an application that receives messages from a topic, processes them and writes the processing results to a database table.

During the operation of the program, two types of work streams are simulated:

- Input stream: messages are written to the topic in the non-transaction mode. The user can control the writing speed, the message size, the number of producers.
- Processing flow: messages are read from the topic and written to the table using the YDB transaction.

The following actions are performed in the processing flow within a single transaction:

- messages from the topic are being read until the `--commit-period` period has expired;
- one `UPSERT` command and a `COMMIT` command are executed on the table to commit the transaction after the period expires.

Command syntax:

```
ydb [global options...] workload transfer topic-to-table run [options...]
```

- `global options` — global parameters.
- `options` - parameters of the subcommand.

View the command description:

```
ydb workload transfer topic-to-table run --help
```

Parameters of the subcommand:

Parameter name	Parameter Description	Default value
`--seconds`, `-s`	Duration of the test in seconds	`60`
`--window`, `-w`	Duration of the statistics collection window in seconds	`1`

`--quiet`, `-q`	Output only the final test result	`0`
`--print-timestamp`	Print the time together with the statistics of each time window	`0`
`--percentile`	Percentile in statistics output	`50`
`--warmup`	The warm-up time of the test in seconds. No statistics are calculated during this time	`5`
`--topic`	Topic name	`transfer-topic`
`--consumer-prefix`	Prefix of the consumers name	`workload-consumer`
`--table`	Table name	`transfer-table`
`--producer-threads`, `-p`	Number of producer threads	`1`
`--consumer-threads`, `-t`	Number of consumer threads	`1`
`--consumers`, `-c`	Number of consumers	`1`
`--message-size`, `-m`	Message size in bytes. It is possible to specify in KB, MB, GB by adding suffixes `K`, `M`, `G` respectively	`10240`
`--message-rate`	Target total write speed. In messages per second. Excludes the use of the `--byte-rate` parameter	`0`
`--byte-rate`	Target total write speed. In bytes per second. Excludes the use of the `--message-rate` parameter. It is possible to specify in KB/s, MB/s, GB/s by adding suffixes `K`, `M`, `G` respectively	`0`
`--tx-commit-interval`	The period between transaction `COMMIT` calls. In milliseconds	`1000`
`--tx-commit-messages`	The period between transaction `COMMIT` calls. In number of messages	`1000000`
`--only-topic-in-tx`	Only topic partitions are forced to participate in transactions. Excludes the use of the `--only-table-in-tx` parameter	`0`
`--only-table-in-tx`	Only table shards are forced to participate in transactions. Excludes the use of the `--only-topic-in-tx` parameter	`0`

For example, the command `ydb --profile quickstart workload transfer topic-to-table run` will run a test lasting 60 seconds. The data for the first 5 seconds will not be taken into account in the work statistics. Example of console output:

```
Window  Write speed     Write time      Inflight        Read speed      Topic time      Select time     Upser
t time     Commit time
#       msg/s   MB/s    percentile,ms   percentile,msg  msg/s   MB/s    percentile,ms   percentile,ms   perce
ntile,ms   percentile,ms
1       0       0       0               0               0       0       0               0               0
0
2       0       0       0               0               0       0       0               0               0
0
3       0       0       0               0               0       0       0               0               0
0
4       0       0       0               0               0       0       0               0               0
0
5       0       0       0               0               0       0       0               0               0

0
...
```

- `Window` — the serial number of the time window for collecting statistics.
- `Write speed` — the speed of writing messages by producers. In messages per second and in megabytes per second.
- `Write time` — the specified percentile of the message writing time in ms.

- `Inflight` — the maximum number of messages waiting for confirmation for all batches.
- `Lag` — the specified percentile of maximum number of messages waiting to be read in the statistics collection window. Messages for all batches are taken into account.
- `Lag time` — the specified percentile of message delay time in ms.
- `Read speed` — the speed of reading messages by consumers. In messages per second and in megabytes per second.
- `Select time`, `Upsert time`, `Commit time` — the specified percentile of the execution time of Select, Insert, Commit operations in ms.

Removing the test environment

After the test is completed, you can delete the test environment.

Command syntax:

```
ydb [global options...] workload transfer topic-to-table clean [options...]
```

- `global options` — global parameters.
- `options` - parameters of the subcommand.

View the command description:

```
ydb workload transfer topic-to-table clean --help
```

Parameters of the subcommand:

Parameter Name	Parameter Description	Default value
`--topic`	Topic name	`transfer-topic`
`--table`	Table name	`transfer-table`

For example, the command `ydb --profile quickstart workload transfer topic-to-table clean` will delete the topic `transfer-topic`, its consumers and the table `transfer-table`.

TPC-C Workload

The workload is based on the TPC-C specification, with the queries and table schemas adapted for YDB.

TPC-C is an industry-standard On-Line Transaction Processing (OLTP) benchmark. It simulates a retail company with a configurable number of warehouses, each containing 10 districts and 3,000 customers per district. A corresponding inventory exists for the warehouses. Customers place orders composed of several items. The company tracks payments, deliveries, and order history, and periodically performs inventory checks.

As a result, the benchmark generates a workload of concurrent distributed transactions with varying types and complexities.

In TPC-C, the warehouse is the basic scale unit: the more warehouses you configure, the larger the dataset and the higher the transaction volume. Each warehouse holds roughly 100 MiB of data. The maximum number of warehouses a YDB cluster can sustain depends on hardware capacity, configuration, and inter-node network latency. As a rule of thumb, allocating about 50 warehouses per compute CPU core is a good starting point.

Here is a quick start snippet:

```
ydb workload tpcc --path tpcc/10wh init -w 10
ydb workload tpcc --path tpcc/10wh import -w 10
ydb workload tpcc --path tpcc/10wh run -w 10
```

By default, when executed in an interactive terminal, both the `import` and `run` commands display their execution progress using a Terminal User Interface (TUI).

Common Command Options

All commands support the common `--path` option, which specifies the path to the directory containing the benchmark tables in the database:

```
ydb workload tpcc --path tpcc/10wh ...
```

Available Options

Name	Description	Default value
`--path` or `-p`	Database path where the benchmark tables are located.	`/`

Initializing a Load Test

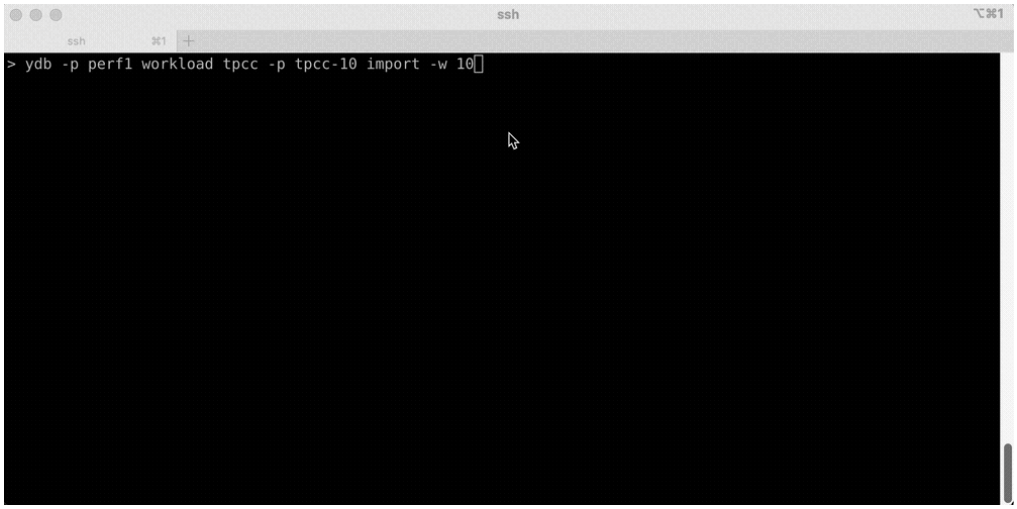
Before running the benchmark, create the tables:

```
ydb workload tpcc --path tpcc/10wh init --warehouses 10
```

See the command description:

```
ydb workload tpcc init --help
```

Available parameters



Name	Description	Default value
`--warehouses` or `-w`	A number of TPC-C warehouses.	10

Loading data into a table

The data will be generated and loaded into the tables directly by ydb:

```
ydb workload tpcc --path tpcc/10wh import --warehouses 10
```

Example usage:

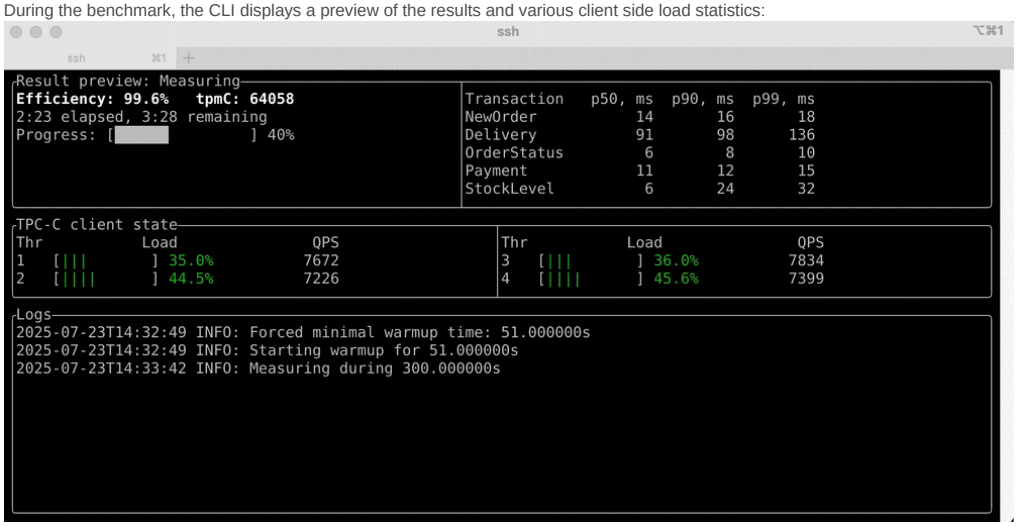
See the command description:

```
ydb workload tpcc import --help
```

Available options

Name	Description	Default value
`--warehouses` or `-w`	A number of TPC-C warehouses.	10
`--compact`	Compact tables after importing data.	
`--threads`	A number of threads loading the TPC-C data to the database.	auto
`--no-tui`	Disable TUI, which is enabled by default in interactive mode.	

The optimal number of loading threads depends on your YDB cluster's size and configuration. As a rule of thumb, for clusters with several hundred CPU cores, starting with around 50 loading threads is reasonable. For larger clusters, you can scale this number further.



However, on the client side, it is recommended to keep the number of loading threads to no more than 50–75% of the available CPU cores.

Run the load test

Run the load:

```
ydb workload tpcc --path tpcc/10wh run --warehouses 10
```

During the benchmark, the CLI displays a preview of the results and various client side load statistics:

See the command description:

```
ydb workload tpcc run --help
```

Available options

Name	Description	Default value
`--warehouses` or `-w`	A number of TPC-C warehouses.	10
`--warmup`	Warmup time. Example: 10s, 5m, 1h.	auto
`--time` or `-t`	Execution time. Example: 10s, 5m, 1h.	2h
`--max-sessions` or `-m`	A soft limit on the number of DB sessions.	auto
`--threads`	A number of threads executing queries	auto
`--format` or `-f`	Output format: 'Pretty', 'Json'	Pretty
`--no-tui`	Disable TUI, which is enabled by default in interactive mode.	

The optimal number of sessions depends on your YDB cluster's size and configuration. As a rule of thumb, a good starting point is to multiply the total number of CPU cores allocated to YDB compute (dynnodes) by 5–10.

We recommend starting with a multiplier of 5. If YDB is underutilized during the benchmark run, consider increasing the number of sessions.

Results

Benchmark results include tpmC, efficiency, and per-transaction-type latencies. As stated by the official specification:

> "The performance metric reported by TPC-C is a "business throughput" measuring the number of orders processed per minute. Multiple transactions are used to simulate the business activity of processing an order, and each transaction is subject to a response time constraint. The performance metric for this benchmark is expressed in transactions-per-minute-C (tpmC)."

The TPC-C specification limits the number of transactions that can be processed per warehouse. The theoretical maximum is 12.86 tpmC per warehouse. To increase the overall load—and thereby the tpmC—you must scale the number of warehouses.

Efficiency is calculated using the following formula:

Test data cleaning

Run cleaning:

```
ydb workload tpcc --path tpcc/10wh clean
```

The command has no parameters.

Data consistency check

`check` command verifies the consistency of TPC-C data. It can be executed after either the `import` or `run` commands. The `check` command is intended primarily for development and is of limited interest to end users.

Example:

```
ydb workload tpcc --path tpcc/10wh check
```

See the command description:

```
ydb workload tpcc check --help
```

Available options

Name	Description	Default value
`--warehouses` or `-w`	A number of TPC-C warehouses.	10
`--just-imported`	Turns on additional checks. Should be used only when data has been just imported and no runs have been done yet.	

TPC-H workload

The workload is based on the TPC-H specification, with the queries and table schemas adapted for YDB.

The benchmark generates a workload typical for decision support systems.

Common command options

All commands support the common `--path` option, which specifies the path to the directory containing tables in the database:

```
ydb workload tpch --path tpch/s1 ...
```

Available options

Name	Description	Default value
`--path` or `-p`	Path to the directory with tables.	`/`

Initializing a load test

Before running the benchmark, create a table:

```
ydb workload tpch --path tpch/s1 init
```

See the command description:

```
ydb workload tpch init --help
```

Available parameters

Name	Description	Default value
`--store <value>`	Table storage type. Possible values: `row`, `column`, `external-s3`.	`column`
`--external-s3-prefix <value>`	Relevant only for external tables. Root path to the dataset in S3 storage.	
`--external-s3-endpoint <value>` or `-e <value>`	Relevant only for external tables. Link to the S3 bucket with data.	
`--string`	Use the `String` type for text fields.	`Utf8`
`--datetime`	Use for time-related fields of type `Date`, `Datetime`, and `Timestamp`.	`Date32`, `Datetime64`, `Timestamp64`
`--partition-size`	Maximum partition size in megabytes (AUTO_PARTITIONING_PARTITION_SIZE_MB) for row tables.	2000
`--float-mode <value>`	Specifies the data type to use for fractional fields. Possible values are `double` and `decimal`. `double` uses the `Double` type, `decimal` uses `Decimal` with dimensions specified by the test standard.	`double`
`--scale`	Sets the percentage of the benchmark's data size and workload to use, relative to full scale.	1
`--clear`	If the table at the specified path already exists, it will be deleted.	

Loading data into a table

The data will be generated and loaded into a table directly by ydb:

```
ydb workload tpch --path tpch/s1 import generator --scale 1
```

See the command description:

```
ydb workload tpch import --help
```

Available options

Name	Description	Default value
`--scale <value>`	Data scale. Powers of ten are usually used. Also supports fractional scale, which is not described in the TPC-H specification. It can be useful for quickly testing small YDB databases. Examples: `0.1`, `0.3`.	
`--tables <value>`	Comma-separated list of tables to generate. Available tables: `customer`, `nation`, `order_line`, `part_psupp`, `region`, `supplier`.	All tables
`--proccess-count <value>` or `-C <value>`	Data generation can be split into several processes, this parameter specifies the number of processes.	1

`--proccess-index <value>` or `-i <value>`	Data generation can be split into several processes, this parameter specifies the process number.	0
`--state <path>`	Path to the generation state file. If the generation was interrupted for some reason, the download will be continued from the same place when it is started again.	
`--clear-state`	Relevant if the `--state` parameter is specified. Clear the state file and start the download from the beginning.	
`--dry-run`	Do not execute loading queries, but only display their text.	

Common parameters of the import command

Name	Description	Default value
`--upload-threads <value>` or `-t <value>`	The number of execution threads for data preparation.	The number of available cores on the client.
`--bulk-size <value>`	The size of the chunk for sending data, in rows.	10000
`--max-in-flight <value>`	The maximum number of data chunks that can be processed simultaneously.	128
`--file-output-path <value>` or `-f <path>`	If this option is set, the data will not be loaded into the database, but will be saved to the directory .	

Run the load test

Run the load:

```
ydb workload tpch --path tpch/s1 run
```

During the test, load statistics are displayed for each request.

See the command description:

```
ydb workload tpch run --help
```

Common parameters for all load types

Name	Description	Default value
`--dry-run`	Do not execute initialization queries, but only display their text.	
`--check-canonical` or `-c`	Use special version of queries (they have deterministic answers) and compare results with canonical ones.	
`--output <value>`	The name of the file where the query execution results will be saved.	`results.out`
`--iterations <value>`	The number of times each load query will be executed.	`1`
`--json <name>`	The name of the file where query execution statistics will be saved in `json` format.	Not saved by default
`--ministat <name>`	The name of the file where query execution statistics will be saved in `ministat` format.	Not saved by default
`--csv <name>`	The name of the file to save the CSV version of the result table.	Not saved by default
`--plan <name>`	The name of the file to save the query plan. Files like `<name>.<query number>.explain` and `<name>.<query number>.<iteration number>` will be saved in formats: `ast`, `json`, `svg`, and `table`.	Not saved by default
`--query-prefix <setting>`	Query prefix. Every prefix is a line that will be added to the beginning of each query. For multiple prefix lines use this option several times.	Not specified by default
`--retries`	Max retry count for every request.	`0`
`--include`	Names, numbers or ranges of query numbers to be executed as part of the load. Specified as a comma-separated list, e.g.: `1,2,4-6`.	All queries executed
`--exclude`	Names, numbers or ranges of query numbers to be excluded from the load. Specified as a comma-separated list, e.g.: `1,2,4-6`.	None excluded by default
`--verbose` or `-v`	Print additional information to the screen during query execution.	
`--global-timeout <value>`	Global timeout for all queries. Supports time units (e.g., '5s', '1m'). Plain number interpreted as milliseconds.	Not specified by default. The time is unlimited.
`--request-timeout <value>`	Timeout for each iteration of each query. Supports time units (e.g., '5s', '1m'). Plain number interpreted as milliseconds.	Not specified by default. The time is unlimited.
`--threads <value>` or `-t <value>`	The number of parallel threads generating the load. Zero means that queries will be executed in the main thread; otherwise, queries will be mixed.	`0`

`--stats <value>`	Extended execution statistics collection mode. Available values: `full`, `profile`.	`full`

TPC-H-specific options

Name	Description	Default value
`--syntax <value>`	Syntax of the queries to use. Available values: `yql`. For more information about working with YQL syntax, see here.	`yql`
`--float-mode <value>`	Float mode. Can be `float`, `decimal` or `decimal_ydb`. If the value is `float` - float will be used, `decimal` means that decimal with canonical size specified in the TPC-H specification (`Decimal(12, 2)`) will be used, and `decimal_ydb` means that all float will be converted to `Decimal(22, 9)`. For more information about the Decimal type, see documentation.	`float`
`--scale <value>`	Scale factor. See the TPC-H specification, chapter 3. Used in TPC-H queries. Also supports fractional scale, which is not described in the TPC-H specification. It can be useful for quickly testing small YDB databases. Examples: `0.1`, `0.3`. For scale factors `1`, `10`, `100`, `1000` canonical answers are specified (see the `--check-canonical` option description).	1

Test data cleaning

Run cleaning:

```
ydb workload tpch --path tpch/s1 clean
```

The command has no parameters.

TPC-DS workload

The workload is based on the TPC-DS specification, with the queries and table schemas adapted for YDB.

This benchmark generates a workload typical for decision support systems.

Common command options

All commands support the common option `--path`, which specifies the path to the directory containing benchmark tables in the database:

```
ydb workload tpcds --path tpcds/s1 ...
```

Available options

Name	Description	Default value
`--path` or `-p`	Path to the directory with tables.	`/`

Initializing the load test

Before running the benchmark, create a table:

```
ydb workload tpcds --path tpcds/s1 init
```

See the command description to run the load:

```
ydb workload tpcds init --help
```

Available parameters

Name	Description	Default value
`--store <value>`	Table storage type. Possible values: `row`, `column`, `external-s3`.	`column`
`--external-s3-prefix <value>`	Relevant only for external tables. Root path to the dataset in S3 storage.	
`--external-s3-endpoint <value>` or `-e <value>`	Relevant only for external tables. Link to the S3 bucket with data.	
`--string`	Use the `String` type for text fields.	`Utf8`
`--datetime`	Use for time-related fields of type `Date`, `Datetime`, and `Timestamp`.	`Date32`, `Datetime64`, `Timestamp64`
`--partition-size`	Maximum partition size in megabytes (AUTO_PARTITIONING_PARTITION_SIZE_MB) for row tables.	2000
`--float-mode <value>`	Specifies the data type to use for fractional fields. Possible values are `double` and `decimal`. `double` uses the `Double` type, `decimal` uses `Decimal` with dimensions specified by the test standard.	`double`
`--scale`	Sets the percentage of the benchmark's data size and workload to use, relative to full scale.	1
`--clear`	If the table at the specified path already exists, it will be deleted.	

Loading data into the table

The data will be generated and loaded into the table directly by YDB CLI:

```
ydb workload tpcds --path tpcds/s1 import generator --scale 1
```

See the command description:

```
ydb workload tpcds import --help
```

Available options

Name	Description	Default value
`--scale <value>`	Data scale. Typically, powers of ten are used. Also supports fractional scale, which is not described in the TPC-DS specification. It can be useful for quickly testing small YDB databases. Examples: `0.1`, `0.3`.	
`--tables <value>`	Comma-separated list of tables to generate. Available tables: `customer`, `nation`, `order_line`, `part_psupp`, `region`, `supplier`.	All tables
`--process-count <value>` or `-C <value>`	Specifies the number of processes for parallel data generation.	`1`

`--process-index <value>` or `-i <value>`	Specifies the process number when data generation is split into multiple processes.	`0`
`--state <path>`	Path to the state file for resuming generation. If the generation is interrupted, it will resume from the same point when restarted.	
`--clear-state`	Relevant if the `--state` parameter is specified. Clears the state file and restarts the download from the beginning.	
`--dry-run`	Do not execute loading queries, but only display their text.	

Common parameters of the import command

Name	Description	Default value
`--upload-threads <value>` or `-t <value>`	The number of execution threads for data preparation.	The number of available cores on the client.
`--bulk-size <value>`	The size of the chunk for sending data, in rows.	10000
`--max-in-flight <value>`	The maximum number of data chunks that can be processed simultaneously.	128
`--file-output-path <value>` or `-f <path>`	If this option is set, the data will not be loaded into the database, but will be saved to the directory .	

Run the load test

Run the load:

```
ydb workload tpcds --path tpcds/s1 run
```

During the benchmark, load statistics are displayed for each request.

See the command description:

```
ydb workload tpcds run --help
```

Common parameters for all load types

Name	Description	Default value
`--dry-run`	Do not execute initialization queries, but only display their text.	
`--check-canonical` or `-c`	Use special version of queries (they have deterministic answers) and compare results with canonical ones.	
`--output <value>`	The name of the file where the query execution results will be saved.	`results.out`
`--iterations <value>`	The number of times each load query will be executed.	`1`
`--json <name>`	The name of the file where query execution statistics will be saved in `json` format.	Not saved by default
`--ministat <name>`	The name of the file where query execution statistics will be saved in `ministat` format.	Not saved by default
`--csv <name>`	The name of the file to save the CSV version of the result table.	Not saved by default
`--plan <name>`	The name of the file to save the query plan. Files like `<name>.<query number>.explain` and `<name>.<query number>.<iteration number>` will be saved in formats: `ast`, `json`, `svg`, and `table`.	Not saved by default
`--query-prefix <setting>`	Query prefix. Every prefix is a line that will be added to the beginning of each query. For multiple prefix lines use this option several times.	Not specified by default
`--retries`	Max retry count for every request.	`0`
`--include`	Names, numbers or ranges of query numbers to be executed as part of the load. Specified as a comma-separated list, e.g.: `1,2,4-6`.	All queries executed
`--exclude`	Names, numbers or ranges of query numbers to be excluded from the load. Specified as a comma-separated list, e.g.: `1,2,4-6`.	None excluded by default
`--verbose` or `-v`	Print additional information to the screen during query execution.	
`--global-timeout <value>`	Global timeout for all queries. Supports time units (e.g., '5s', '1m'). Plain number interpreted as milliseconds.	Not specified by default. The time is unlimited.
`--request-timeout <value>`	Timeout for each iteration of each query. Supports time units (e.g., '5s', '1m'). Plain number interpreted as milliseconds.	Not specified by default. The time is unlimited.
`--threads <value>` or `-t <value>`	The number of parallel threads generating the load. Zero means that queries will be executed in the main thread; otherwise, queries will be mixed.	`0`

`--stats <value>`	Extended execution statistics collection mode. Available values: `full`, `profile`.	`full`

TPC-DS-specific options

Name	Description	Default value
`--syntax <value>`	Syntax of the queries to use. Available values: `yql`. For more information about working with YQL syntax, see here.	`yql`
`--float-mode <value>`	Float mode. Can be `float`, `decimal` or `decimal_ydb`. If the value is `float` - float will be used, `decimal` means that decimal with canonical size specified in the TPC-DS specification (`Decimal(12, 2)`) will be used, and `decimal_ydb` means that all float will be converted to `Decimal(22, 9)`. For more information about the Decimal type, see documentation.	`float`
`--scale <value>`	Scale factor. See the TPC-DS specification, chapter 3. Used in TPC-DS queries. Also supports fractional scale, which is not described in the TPC-DS specification. It can be useful for quickly testing small YDB databases. Examples: `0.1`, `0.3`. For scale factors `1`, `10`, `100`, `1000` canonical answers are specified (see the `--check-canonical` option description).	1

Test data cleanup

Run cleanup:

```
ydb workload tpcds --path tpcds/s1 clean
```

The command has no parameters.

User workload

Allows you to perform load testing according to a specified user scenario.

A test scenario is a directory called `suite`, which contains a set of subdirectories: `init`, `import`, and `run`, corresponding to the `ydb workload query` commands.

- The `init` directory can have an arbitrary structure and contains SQL queries for creating and configuring objects in the database, such as tables or indexes.
- The `import` directory contains data to be loaded into tables. Each table corresponds to a subdirectory in the `import` directory.
- The `run` directory can have an arbitrary structure and contains SQL queries for load testing.

Example of a `suite` directory on GitHub.

The user specifies the path to the `suite` directory using the `--suite-path` option in each command.

General syntax

General syntax for calling user workload commands:

```
ydb [global options...] workload query [--path <path/in/db>] <command> [options...]
```

- `global options` — global parameters.
- `--path` — the path in the database for load testing objects.
- `<command>` — one of the commands: `init`, `import`, `run`, `clean`.
- `options` — parameters for a specific command.

Common command parameters

All commands support the common `--path` parameter, which sets the path in the database for load testing objects. All created objects will be created at this path. The path will also be taken into account during test execution and cleanup.

Available parameters

Name	Description	Default value
`--path` or `-p`	Path in the database for load testing objects.	`/`

Load test initialization

Before starting the test, create tables and other database objects:

```
ydb workload query --path user_path init --suite-path ~/user-suite
```

The `init` command works as follows:

- If a `suite` is specified and it contains an `init` directory, the `init` directory is scanned, including its nested directories, using a depth-first search with lexicographical ordering of files and subdirectories at each level.
- Files with `.sql` and `.yql` extensions are selected.
- The content of each file is read and executed sequentially as an SQL query.
- After that, queries specified directly from the command line using the `--query` parameter are executed.
- If any of the queries result in an error, the command execution stops.

It is assumed that relatively "lightweight" queries, such as creating tables and indexes, are performed at this stage. It is not recommended to include scripts for filling tables with data in the files in the `init` directory. These operations should be moved to the `import` phase.

Macros can be used in queries:

- `{db}` — The absolute path in the database to the testing directory. It is a combination of the `--database` and `--path` option values.

View the command description for initializing tables:

```
ydb workload query init --help
```

Available parameters

Name	Description	Default value
`--suite-path <path>`	Path to the `suite` directory.	
`--query <query>` or `-q <query>`	DDL query to execute. Can be used multiple times.	
`--clear`	If a table being created already exists at the specified path, it will be deleted first.	
`--dry-run`	Do not execute initialization queries, only print them.	

Loading data into a table

Load data into tables:

```
ydb workload query --path user_path import --suite-path ~/user-suite
```

The `import` command works as follows:

- If a `suite` is specified and it contains an `import` directory, it performs a sequential traversal of its subdirectories.
- It is assumed that each subdirectory corresponds to a table in the database.
- Files in supported data formats are used in the subdirectory, namely `csv`, `tsv`, `csv.gz`, `tsv.gz`, and `parquet`.
- Data is loaded from files into the corresponding tables. Loading is multi-threaded, with both the loading of different files and parts of a single file being parallelized. The order of loading is not guaranteed.

The loading process can take a long time and may be interrupted for some reason. To be able to continue loading from the point of interruption, a state mechanism can be applied. Using the `--state` option, you can specify the path to a state file. If the state file exists, it will be used to continue loading. If there is no state file, it will be created during the loading process. It can also be cleared using the `--clear-state` option.

View the command description for loading data:

```
ydb workload query import --help
```

Available parameters

Name	Description	Default value
`--suite-path <path>`	Path to the `suite` directory.	
`--state <path>`	Path to the loading state file. If the loading was interrupted for some reason, it will be continued from the same place upon a new start.	
`--clear-state`	Relevant if the `--state` parameter is specified. Clear the state file and start loading from the beginning.	
`--dry-run`	Do not load data into the database, only prepare the data and output a message about it.	

Common parameters of the import command

Name	Description	Default value
`--upload-threads <value>` or `-t <value>`	The number of execution threads for data preparation.	The number of available cores on the client.
`--bulk-size <value>`	The size of the chunk for sending data, in rows.	10000
`--max-in-flight <value>`	The maximum number of data chunks that can be processed simultaneously.	128
`--file-output-path <value>` or `-f <path>`	If this option is set, the data will not be loaded into the database, but will be saved to the directory .	

Running a load test

Start the load:

```
ydb workload query --path user_path run --suite-path ~/user-suite
```

The `run` command works as follows:

- If the `suite` contains a `run` directory, the command traverses it and all its nested directories using a depth-first search, ordering files and subdirectories alphabetically at each level. If the `run` directory is missing, execution stops.
- It selects files with `.sql` and `.yql` extensions and includes them in the list of SQL queries.
- After that, it adds queries specified directly from the command line using the `--query` parameter to the list.
- Depending on the options, it either executes all queries sequentially, each query a specified number of times, or in parallel in multiple threads with query shuffling.
- Errors in queries will be recorded in the statistics but will not cause the testing to stop.

During the test, load statistics for each query and aggregated statistics for all queries are displayed on the screen.

View the command description for starting the load:

```
ydb workload query run --help
```

Common parameters for all load types

Name	Description	Default value
`--dry-run`	Do not execute initialization queries, but only display their text.	
`--check-canonical` or `-c`	Use special version of queries (they have deterministic answers) and compare results with canonical ones.	
`--output <value>`	The name of the file where the query execution results will be saved.	`results.out`
`--iterations <value>`	The number of times each load query will be executed.	`1`
`--json <name>`	The name of the file where query execution statistics will be saved in `json` format.	Not saved by default
`--ministat <name>`	The name of the file where query execution statistics will be saved in `ministat` format.	Not saved by default

`--csv <name>`	The name of the file to save the CSV version of the result table.	Not saved by default
`--plan <name>`	The name of the file to save the query plan. Files like `<name>.<query number>.explain` and `<name>.<query number>.<iteration number>` will be saved in formats: `ast`, `json`, `svg`, and `table`.	Not saved by default
`--query-prefix <setting>`	Query prefix. Every prefix is a line that will be added to the beginning of each query. For multiple prefix lines use this option several times.	Not specified by default
`--retries`	Max retry count for every request.	`0`
`--include`	Names, numbers or ranges of query numbers to be executed as part of the load. Specified as a comma-separated list, e.g.: `1,2,4-6`.	All queries executed
`--exclude`	Names, numbers or ranges of query numbers to be excluded from the load. Specified as a comma-separated list, e.g.: `1,2,4-6`.	None excluded by default
`--verbose` or `-v`	Print additional information to the screen during query execution.	
`--global-timeout <value>`	Global timeout for all queries. Supports time units (e.g., '5s', '1m'). Plain number interpreted as milliseconds.	Not specified by default. The time is unlimited.
`--request-timeout <value>`	Timeout for each iteration of each query. Supports time units (e.g., '5s', '1m'). Plain number interpreted as milliseconds.	Not specified by default. The time is unlimited.
`--threads <value>` or `-t <value>`	The number of parallel threads generating the load. Zero means that queries will be executed in the main thread; otherwise, queries will be mixed.	`0`
`--stats <value>`	Extended execution statistics collection mode. Available values: `full`, `profile`.	`full`

Query-specific options

Name	Description	Default value
`--suite-path <path>`	Path to the `suite` directory.	
`--query <query>` or `-q <query>`	Query to execute. Can be used multiple times.	

Canonical results

A canonical (expected) result can be specified for each query from a file. If the query response does not match the canonical one, this will be reflected in the statistics and command output. Differences will also be provided.

The canonical result is specified using a file with the same name and an additional `.result` extension. These are CSV files with headers and some additional syntax:

- If a query has more than one result set, the result file must contain the corresponding number of datasets separated by empty lines.

  For example, the query

  ```
  SELECT COUNT(*) AS count FROM table_1;
  SELECT MIN(col1) AS min, MAX(col1) AS max FROM table_2;
  ```

  Might have the following result file:

  ```
  count
  10

  min,max
  4,5
  ```

- The last line can be specified as `...`, which means that the query result can have more lines than in the canonical result, but the first lines of the result must match the canonical ones.
- By default, floating-point numbers are compared with a relative precision of `1e-3` percent, but in the canonical result, you can specify any absolute or relative precision for each value, for example: `1.5+-0.01`, `2.4e+10+-1%`.

For queries specified with the `--query` option, a canonical result cannot be set.

The canonical result will not be used unless the `--check-canonical` flag is set.

Cleaning up test data

Start the cleanup:

```
ydb workload query --path user_path clean
```

Performs recursive deletion of database objects at the path specified in the `--path` parameter.

The command has no parameters.

Example of running a user test

Download an example from the repository

```
git clone https://github.com/ydb-platform/ydb.git
cd ydb/ydb/tests/functional/tpc/data/e1
```

Start initialization

```
ydb workload query --path test_path init --suite-path .
```

Result:

```
Init tables ...
Init tables ...Ok
```

Start data import

```
ydb workload query --path test_path import --suite-path .
```

Result:

```
Fill table test_table_1...
Fill table test_table_1 OK 0 / 0 (0.353816s)
Fill table test_table_2...

Fill table test_table_2 OK 0 / 0 (0.102385s)
```

Start the load test

```
ydb workload query --path user_path run --suite-path e1
```

Result:

```
first_query_set.1.sql:
    iteration 0:    ok    0.131573s seconds
first_query_set.2.yql:
    iteration 0:    ok    0.089327s seconds
second_query_set.join.sql:
    iteration 0:    ok    0.145536s seconds

Results for 1 iterations
┌──────────────────────────┬──────────┬──────────┬──
```

Fulltext load

Allows you to test YDB fulltext search performance using a document dataset. Supports both real datasets (e.g., MS MARCO) and synthetically generated text based on a Markov chain model.

The Markov model assumes that each next word depends on one or more previous words. The number of previous words on which the next word is based is called the model's order. First, we use an ordinary random generator with a uniform distribution to determine the text length, which we will then generate word by word using the Markov model until we reach the required number of words. Such data construction is necessary so that the text resembles some real human text rather than being just a random jumble of letters. A Markov model can be used both for generating the text of documents stored in a database and for generating select and upsert queries.

Command structure

```
ydb [global options...] workload fulltext [options...] <subcommand>
```

Subcommands:

```
fulltext            YDB fulltext workload
├─ init               Initialize tables for the workload
├─ import             Load data and build a fulltext index
│   ├─ files            Import data from files
│   └─ generator        Generate random text using a Markov chain model
├─ run                Run the workload
│   ├─ select           Search documents using fulltext queries
│   └─ upsert           Insert or update documents in the table
├─ clean              Drop tables created for load testing
└─ model              Build a Markov chain model from a text dataset
```

Common command options

All commands support the following option:

Name	Description	Default value
`--path` or `-p`	Path in the database where workload tables will be created.	`fulltext_workload`

Initializing the workload

Create the tables for the workload:

```
ydb workload fulltext init
```

Available options

Name	Description	Default value
`--min-partitions <value>`	Minimum number of table partitions.	`40`
`--partition-size <value>`	Target partition size, in MB.	`2000`
`--auto-partition <value>`	Enable auto-partitioning by load (`1` — enabled, `0` — disabled).	`1`
`--clear`	Drop and recreate the table if it already exists.	

Loading data

After initialization, load data into the table and build the fulltext index. There are two subcommands: `files` to import from an existing dataset and `generator` to generate synthetic data.

After import is complete, a fulltext index named `index` is automatically built on the `text` column.

Importing from files

Import documents from files (CSV, TSV, or Parquet, optionally gzip-compressed). The dataset must contain `id` and `text` columns. In the internal table, the `id` column is stored as `Uint64` and the `text` column as `String`.

Example:

```
ydb workload fulltext import files
```

Available options

Name	Description	Default value
`--input <path>` or `-i <path>`	Path to the dataset file or directory. Supported formats: CSV/TSV (optionally gzip-compressed), Parquet. Only `id` and `text` columns are imported.	Required

Common parameters of the import command

Name	Description	Default value
`--upload-threads <value>` or `-t <value>`	The number of execution threads for data preparation.	The number of available cores on the client.

`--bulk-size <value>`	The size of the chunk for sending data, in rows.	10000
`--max-in-flight <value>`	The maximum number of data chunks that can be processed simultaneously.	128
`--file-output-path <value>` or `-f <path>`	If this option is set, the data will not be loaded into the database, but will be saved to the directory .	

Generating synthetic data

Generate random text data using a Markov chain model and load it into the table. You must first build the model or download a pre-built one.

- To load an already built model:

```
wget https://storage.yandexcloud.net/ydb-public/markov_dict.tsv.gz
```

- To create your own model from Wikipedia data:

```
from datasets import load_dataset

ds = load_dataset(
   "rumbleFTW/wikipedia-20220301-en-raw",
   split="train[:1000000]",
   streaming=False,
   )
ds.to_csv('wikipedia_sample.csv.gz', compression='gzip', index=False)
```

```
ydb workload fulltext import generator
```

Available options

Name	Description	Default value
`--model <path>` or `-m <path>`	Path to the Markov chain model file (`.tsv.gz`).	Required
`--rows <value>`	Number of rows to generate.	`100000`
`--min-sentence-len <value>`	Minimum number of words in a generated document.	`100`
`--max-sentence-len <value>`	Maximum number of words in a generated document.	`1000`

We use parameters `--min-sentence-len` and `--max-sentence-len` to generate target text length with uniform distribution.

Common parameters of the import command

Name	Description	Default value
`--upload-threads <value>` or `-t <value>`	The number of execution threads for data preparation.	The number of available cores on the client.
`--bulk-size <value>`	The size of the chunk for sending data, in rows.	10000
`--max-in-flight <value>`	The maximum number of data chunks that can be processed simultaneously.	128
`--file-output-path <value>` or `-f <path>`	If this option is set, the data will not be loaded into the database, but will be saved to the directory .	

Running the workload

Run load testing using one of two modes: `select` (fulltext search queries) or `upsert` (inserting new documents).

Search workload

Executes fulltext search queries against the indexed table. Queries can be generated from a Markov chain model or read from a pre-loaded query table.

```
ydb workload fulltext run select --model markov_dict.tsv.gz
```

Available options

Name	Description	Default value
`--model <path>` or `-m <path>`	Path to the Markov chain model file (`.tsv.gz`) for generating queries. Either `--model` or `--query-table` must be specified.	
`--query-table <name>`	Name of the table containing pre-loaded queries. The table must have a `query` column. Either `--model` or `--query-table` must be specified.	
`--index-name <name>`	Name of the fulltext index to use.	`index`
`--min-query-len <value>`	Minimum number of words in a generated query.	`1`
`--max-query-len <value>`	Maximum number of words in a generated query.	`5`

`--top-size <value>`	Number of rows to sample from the table to build the query word set.	`1000`
`--limit <value>`	Limit the number of results returned per query. `0` means no limit.	`0`

Common parameters for all load types

Name	Description	Default value
`--dry-run`	Do not execute initialization queries, but only display their text.	
`--check-canonical` or `-c`	Use special version of queries (they have deterministic answers) and compare results with canonical ones.	
`--output <value>`	The name of the file where the query execution results will be saved.	`results.out`
`--iterations <value>`	The number of times each load query will be executed.	`1`
`--json <name>`	The name of the file where query execution statistics will be saved in `json` format.	Not saved by default
`--ministat <name>`	The name of the file where query execution statistics will be saved in `ministat` format.	Not saved by default
`--csv <name>`	The name of the file to save the CSV version of the result table.	Not saved by default
`--plan <name>`	The name of the file to save the query plan. Files like `<name>.<query number>.explain` and `<name>.<query number>.<iteration number>` will be saved in formats: `ast`, `json`, `svg`, and `table`.	Not saved by default
`--query-prefix <setting>`	Query prefix. Every prefix is a line that will be added to the beginning of each query. For multiple prefix lines use this option several times.	Not specified by default
`--retries`	Max retry count for every request.	`0`
`--include`	Names, numbers or ranges of query numbers to be executed as part of the load. Specified as a comma-separated list, e.g.: `1,2,4-6`.	All queries executed
`--exclude`	Names, numbers or ranges of query numbers to be excluded from the load. Specified as a comma-separated list, e.g.: `1,2,4-6`.	None excluded by default
`--verbose` or `-v`	Print additional information to the screen during query execution.	
`--global-timeout <value>`	Global timeout for all queries. Supports time units (e.g., '5s', '1m'). Plain number interpreted as milliseconds.	Not specified by default. The time is unlimited.
`--request-timeout <value>`	Timeout for each iteration of each query. Supports time units (e.g., '5s', '1m'). Plain number interpreted as milliseconds.	Not specified by default. The time is unlimited.
`--threads <value>` or `-t <value>`	The number of parallel threads generating the load. Zero means that queries will be executed in the main thread; otherwise, queries will be mixed.	`0`
`--stats <value>`	Extended execution statistics collection mode. Available values: `full`, `profile`.	`full`

Upsert workload

Continuously inserts new documents into the table using a Markov chain model to generate text.

```
ydb workload fulltext run upsert --model markov_dict.tsv.gz
```

Available options

Name	Description	Default value
`--model <path>` or `-m <path>`	Path to the Markov chain model file (`.tsv.gz`).	Required
`--index-name <name>`	Name of the fulltext index to use.	`index`
`--bulk-size <value>`	Number of rows per upsert batch.	`100`
`--min-sentence-len <value>`	Minimum number of words in a generated document.	`100`
`--max-sentence-len <value>`	Maximum number of words in a generated document.	`1000`

Common parameters for all load types

Name	Description	Default value
`--dry-run`	Do not execute initialization queries, but only display their text.	
`--check-canonical` or `-c`	Use special version of queries (they have deterministic answers) and compare results with canonical ones.	
`--output <value>`	The name of the file where the query execution results will be saved.	`results.out`

`--iterations <value>`	The number of times each load query will be executed.	`1`
`--json <name>`	The name of the file where query execution statistics will be saved in `json` format.	Not saved by default
`--ministat <name>`	The name of the file where query execution statistics will be saved in `ministat` format.	Not saved by default
`--csv <name>`	The name of the file to save the CSV version of the result table.	Not saved by default
`--plan <name>`	The name of the file to save the query plan. Files like `<name>.<query number>.explain` and `<name>.<query number>.<iteration number>` will be saved in formats: `ast`, `json`, `svg`, and `table`.	Not saved by default
`--query-prefix <setting>`	Query prefix. Every prefix is a line that will be added to the beginning of each query. For multiple prefix lines use this option several times.	Not specified by default
`--retries`	Max retry count for every request.	`0`
`--include`	Names, numbers or ranges of query numbers to be executed as part of the load. Specified as a comma-separated list, e.g.: `1,2,4-6`.	All queries executed
`--exclude`	Names, numbers or ranges of query numbers to be excluded from the load. Specified as a comma-separated list, e.g.: `1,2,4-6`.	None excluded by default
`--verbose` or `-v`	Print additional information to the screen during query execution.	
`--global-timeout <value>`	Global timeout for all queries. Supports time units (e.g., '5s', '1m'). Plain number interpreted as milliseconds.	Not specified by default. The time is unlimited.
`--request-timeout <value>`	Timeout for each iteration of each query. Supports time units (e.g., '5s', '1m'). Plain number interpreted as milliseconds.	Not specified by default. The time is unlimited.
`--threads <value>` or `-t <value>`	The number of parallel threads generating the load. Zero means that queries will be executed in the main thread; otherwise, queries will be mixed.	`0`
`--stats <value>`	Extended execution statistics collection mode. Available values: `full`, `profile`.	`full`

Building a Markov chain model

Before using the generator or the `run upsert` / `run select` modes with generated queries, you need to build a Markov chain model from a text dataset. The model captures word transition probabilities and is used to generate realistic text.

```
ydb workload fulltext model --input wikipedia_sample.csv.gz --output markov_dict.tsv.gz --order 3
```

Available options

Name	Description	Default value
`--input <path>` or `-i <path>`	Path to the dataset file or directory. Supports `.csv[.gz]` and `.tsv[.gz]` formats. The file must have a `text` column.	Required
`--output <path>` or `-o <path>`	Output file path for the model dictionary.	`markov_dict.tsv.gz`
`--order <value>` or `-n <value>`	Order of the Markov chain (n-gram context size). Order 1 uses only one word to predict next word, order 2 uses context from two words, etc. Must be between 1 and 5.	`1`

The `--order` parameter specifies the number of previous words used to predict the next word. Typical values range from 1 to 5: lower values produce noisier text, while higher values generate text that is more similar to the source. The size of the Markov model grows exponentially with the `--order` value.

Cleaning up

Drop tables created for load testing:

```
ydb workload fulltext clean
```

Usage examples

Example with a generated dataset

1. Download or train Markov chain model:
   - Download the model from S3:

     ```
     wget https://storage.yandexcloud.net/ydb-public/markov_dict.tsv.gz
     ```

   - Train the model from Wikipedia dataset:

```
from datasets import load_dataset

ds = load_dataset(
   "rumbleFTW/wikipedia-20220301-en-raw",
   split="train[:1000000]",
   streaming=False,
   )
ds.to_csv('wikipedia_sample.csv.gz', compression='gzip', index=False)
```

```
ydb workload fulltext model --input wikipedia_sample.csv.gz --output markov_dict.tsv.gz --order 3
```

2. Initialize the workload table:

```
ydb workload fulltext init
```

3. Generate and load synthetic documents:

```
ydb workload fulltext import generator --model markov_dict.tsv.gz
```

4. Run the search workload:

```
ydb workload fulltext run select --model markov_dict.tsv.gz
```

Output example:

```
Window      Txs Txs/Sec Retries Errors  p50(ms) p95(ms) p99(ms) pMax(ms)
1            23 23      0       0       242     407     453     453
2            18 18      0       1       611     807     915     915
3             6 6       0       7       161     991     991     991
4            35 35      0       0       173     803     923     923
5            59 59      0       1       135     647     759     803
6            26 26      0       0       257     335     339     339
7            15 15      0       1       651     963     975     975
8            11 11      0       1       871     943     963     963
9            18 18      0       6       190     967     999     999
10           31 31      0       1       433     755     995     995

Total       Txs Txs/Sec Retries Errors  p50(ms) p95(ms) p99(ms) pMax(ms)
10          242 24.2    0       18      259     915     991     999
```

Column description:

- Window – Sequential number of the time window (e.g., each second or fixed interval).
- Txs – Number of transactions successfully completed in this window (or total across all windows in the bottom section).
- Txs/Sec – Transaction rate per second for the given window (or average for total).
- Retries – Number of automatic retries performed due to temporary errors (e.g., conflicts or throttling).
- Errors – Number of unrecoverable errors encountered.
- p50(ms) – Median (50th percentile) transaction latency in milliseconds.
- p95(ms) – 95th percentile latency (milliseconds).
- p99(ms) – 99th percentile latency (milliseconds).
- pMax(ms) – Maximum observed latency within the window (or overall maximum for total).

5. Run the upsert workload:

```
ydb workload fulltext run upsert --model markov_dict.tsv.gz
```

Output example:

```
Window      Txs Txs/Sec Retries Errors  p50(ms) p95(ms) p99(ms) pMax(ms)
1           255 255     0       0       31      34      117     123
2           279 279     0       0       32      37      42      45
3           282 282     0       0       31      35      37      40
4           277 277     0       0       32      37      39      42
5           281 281     0       0       32      38      40      42
6           278 278     0       0       32      39      41      43
7           279 279     0       0       32      38      39      43
8           275 275     0       0       33      39      42      46
9           282 282     0       0       32      37      39      40
10          293 293     0       0       31      37      39      41

Total       Txs Txs/Sec Retries Errors  p50(ms) p95(ms) p99(ms) pMax(ms)
10         2781 278.1   0       0       32      38      41      123
```

6. Clean up:

```
ydb workload fulltext clean
```

Example with the MS MARCO dataset

1. Download the quality bundle (contains `documents.tsv.gz`, `queries.tsv.gz`, `markov_dict.tsv.gz`, and `query_relevances.tsv.gz`):

```
wget https://storage.yandexcloud.net/ydb-public/quality-bundle.tar
tar -xf quality-bundle.tar
```

2. Initialize the workload table:

```
ydb workload fulltext init
```

3. Import documents from the dataset:

```
ydb workload fulltext import files
```

4. Run the search workload using the pre-built queries:

```
ydb workload fulltext run select --quality
```

Output example:

```
Search quality measurement...
Search quality measurement completed for 100 queries in 1 seconds.
nDCG@10:  0.270
Errors:   0
Window      Txs Txs/Sec Retries Errors  p50(ms) p95(ms) p99(ms) pMax(ms)
1            23 23      0       0       242     407     453     453
2            18 18      0       1       611     807     915     915
3             6 6       0       7       161     991     991     991
4            35 35      0       0       173     803     923     923
5            59 59      0       1       135     647     759     803
6            26 26      0       0       257     335     339     339
7            15 15      0       1       651     963     975     975
8            11 11      0       1       871     943     963     963
9            18 18      0       6       190     967     999     999
10           31 31      0       1       433     755     995     995

Total       Txs Txs/Sec Retries Errors  p50(ms) p95(ms) p99(ms) pMax(ms)
10          242 24.2    0       18      259     915     991     999
```

5. Run the upsert workload:

```
ydb workload fulltext run upsert
```

Output example:

```
Window      Txs Txs/Sec Retries Errors  p50(ms) p95(ms) p99(ms) pMax(ms)
1           255 255     0       0       31      34      117     123
2           279 279     0       0       32      37      42      45
3           282 282     0       0       31      35      37      40
4           277 277     0       0       32      37      39      42
5           281 281     0       0       32      38      40      42
6           278 278     0       0       32      39      41      43
7           279 279     0       0       32      38      39      43
8           275 275     0       0       33      39      42      46
9           282 282     0       0       32      37      39      40
10          293 293     0       0       31      37      39      41

Total       Txs Txs/Sec Retries Errors  p50(ms) p95(ms) p99(ms) pMax(ms)
10         2781 278.1   0       0       32      38      41      123
```

6. Clean up:

```
ydb workload fulltext clean
```

Vector load

Allows you to test YDB vector search performance and recall using exact and approximate search. Supports both global and filtered vector indexes.

The workload supports importing vectors from a real dataset (e.g., Wikipedia embeddings) or generating synthetic random vectors. After loading data, you can build a vector index, run search queries to measure recall and performance, and clean up the workload tables.

Command structure

```
ydb [global options...] workload vector [options...] <subcommand>
```

Subcommands:

```
vector                YDB vector workload.
├─ init                 Create and initialize tables for the workload
├─ import               Fill workload tables with data
│   ├─ files              Import vectors from files
│   └─ generator          Generate random vectors
├─ build-index          Create and initialize a vector index for the workload
├─ drop-index           Drop the vector index created for the workload
├─ run                  Run YDB vector workload
│   ├─ select            Search vectors and measure performance/recall
│   └─ upsert            Insert or update vector rows in the table
└─ clean                Drop tables created for load testing
```

Initializing the workload

Create the table for the workload:

```
ydb workload vector init
```

Available options

Name	Description	Default value
`--table <name>`	Name of the main table that stores vectors.	`vector_index_workload`
`--min-partitions <value>`	Minimum number of table partitions.	`40`
`--partition-size <value>`	Target partition size, in MB.	`2000`
`--auto-partition <value>`	Enable auto-partitioning by load (`1` — enabled, `0` — disabled).	`1`
`--prefixed`	Add a `prefix` column to the table for use with a filtered (prefixed) vector index.	
`--clear`	Drop and recreate the table if it already exists.	
`--dry-run`	Print the DDL query instead of executing it.	

The created table has the following schema:

- `id Uint64 NOT NULL` — primary key;
- `embedding String` — serialized embedding vector;
- `prefix Uint64 NOT NULL` (only when `--prefixed` is specified) — filter column for prefixed indexes.

Loading data

After initialization, load data into the table. There are two subcommands: `files` to import vectors from an existing dataset and `generator` to generate synthetic random vectors.

After import is complete, a vector index named `index` is automatically built on the `embedding` column (unless `--index-type None` is specified).

Importing from files

Import vectors from files (CSV, TSV, or Parquet, optionally gzip-compressed). The dataset must contain `id` and `embedding` columns. Any additional columns are ignored.

For CSV/TSV files, embeddings must be encoded as a list of floats, e.g., `"[ 1.0, 2.0, 3.0 ]"`. For Parquet files, embeddings can be a list of `float32` values or already serialized YDB binary embeddings.

Example:

```
ydb workload vector import files
```

Available options

Name	Description	Default value
`--input <path>` or `-i <path>`	Path to the dataset file or directory. Supported formats: CSV/TSV (optionally gzip-compressed), Parquet. Only `id` and `embedding` columns are imported.	Required

`--format <format>`	Source files format. One of `csv`, `tsv`, `parquet`. When set, only files matching the specified format are imported from a directory. When not set, format is auto-detected from file extensions.	
`--embedding-column-name <name>`	Alternative source column name for the embedding field in input files.	`embedding`
`--table <name>`	Name of the table to load data into.	`vector_index_workload`
`--index <name>`	Name of the vector index to build after import.	`index`
`--index-type <type>`	Index type to build after import. Possible values: `None`, `KmeansTree`. Set to `None` to skip index building.	`KmeansTree`
`--vector-type <type>`	Type of vectors. One of `float`, `int8`, `uint8`, `bit`.	`float`
`--vector-dimension <value>`	Vector dimension (size of embedding vectors).	`1024`
`--distance <value>`	Distance or similarity function. One of `inner_product`, `cosine`, `euclidean`, `manhattan`.	`inner_product`
`--kmeans-tree-levels <value>`	Number of levels in the kmeans tree. If not set, auto-detected by server. See kmeans-tree type.	Auto-detected
`--kmeans-tree-clusters <value>`	Number of clusters in kmeans. If not set, auto-detected by server. See kmeans-tree type.	Auto-detected
`--kmeans-tree-covering <value>`	Build a covering index (`1` — enabled, `0` — disabled).	`0`
`--kmeans-tree-prefixed <value>`	Build a prefixed (filtered) index (`1` — enabled, `0` — disabled). The table must have been created with the `--prefixed` option.	`0`

Note

For more details on `--kmeans-tree-*` index building parameters, see kmeans-tree type.

Common parameters of the import command

Name	Description	Default value
`--upload-threads <value>` or `-t <value>`	The number of execution threads for data preparation.	The number of available cores on the client.
`--bulk-size <value>`	The size of the chunk for sending data, in rows.	10000
`--max-in-flight <value>`	The maximum number of data chunks that can be processed simultaneously.	128
`--file-output-path <value>` or `-f <path>`	If this option is set, the data will not be loaded into the database, but will be saved to the directory .	

Generating synthetic data

Generate random vectors and load them into the table. Vector components are sampled from a uniform distribution and serialized into YDB binary embedding format.

```
ydb workload vector import generator
```

Available options

Name	Description	Default value
`--rows <value>`	Number of rows to generate.	`10000`
`--prefix-count <value>`	Number of distinct prefix values for a prefixed index.	`100`
`--seed <value>`	Seed for the random number generator.	`42`
`--table <name>`	Name of the table to load data into.	`vector_index_workload`
`--index <name>`	Name of the vector index to build after import.	`index`
`--index-type <type>`	Index type to build after import. Possible values: `None`, `KmeansTree`.	`KmeansTree`
`--vector-type <type>`	Type of vectors. One of `float`, `int8`, `uint8`, `bit`.	`float`
`--vector-dimension <value>`	Vector dimension.	`1024`
`--distance <value>`	Distance or similarity function.	`inner_product`
`--kmeans-tree-levels <value>`	Number of levels in the kmeans tree. If not set, auto-detected by server.	Auto-detected
`--kmeans-tree-clusters <value>`	Number of clusters in kmeans. If not set, auto-detected by server.	Auto-detected

`--kmeans-tree-covering <value>`	Build a covering index.	`0`
`--kmeans-tree-prefixed <value>`	Build a prefixed (filtered) index.	`0`

Note

For more details on `--kmeans-tree-*` index building parameters, see kmeans-tree type.

Common parameters of the import command

Name	Description	Default value
`--upload-threads <value>` or `-t <value>`	The number of execution threads for data preparation.	The number of available cores on the client.
`--bulk-size <value>`	The size of the chunk for sending data, in rows.	10000
`--max-in-flight <value>`	The maximum number of data chunks that can be processed simultaneously.	128
`--file-output-path <value>` or `-f <path>`	If this option is set, the data will not be loaded into the database, but will be saved to the directory .	

Building a vector index

If the table was loaded with `--index-type None`, or if you want to build an additional index with different parameters, you can build a vector index on an existing table using the `build-index` command.

```
ydb workload vector build-index --distance cosine
```

Available options

Name	Description	Default value
`--table <name>`	Name of the table to build the index on.	`vector_index_workload`
`--index <name>`	Name of the index to create.	`index`
`--vector-type <type>`	Type of vectors. One of `float`, `int8`, `uint8`, `bit`.	`float`
`--vector-dimension <value>`	Vector dimension.	`1024`
`--distance <value>`	Distance or similarity function.	`inner_product`
`--kmeans-tree-levels <value>`	Number of levels in the kmeans tree. If not set, auto-detected by server.	Auto-detected
`--kmeans-tree-clusters <value>`	Number of clusters in kmeans. If not set, auto-detected by server.	Auto-detected
`--dry-run`	Print the DDL query instead of executing it.	

Note

For more details on `--kmeans-tree-*` index building parameters, see kmeans-tree type.

Dropping a vector index

Drop a previously built vector index.

```
ydb workload vector drop-index
```

Available options

Name	Description	Default value
`--table <name>`	Name of the table that holds the index.	`vector_index_workload`
`--index <name>`	Name of the index to drop.	`index`
`--dry-run`	Print the DDL query instead of executing it.	

Running the workload

Run load testing using one of two modes: `select` (vector search queries) or `upsert` (inserting new vector rows).

Search workload

Executes vector search queries against the indexed table. Optionally measures recall by comparing approximate search results with exact (full-scan) results, then runs a performance benchmark.

```
ydb workload vector run select --recall
```

Available options

Name	Description	Default value
`--table <name>`	Name of the main table with vectors.	`vector_index_workload`
`--index <name>`	Name of the vector index to use.	`index`
`--query-table <name>`	Name of the table with predefined search vectors. If not specified, random rows from the main table are used.	
`--targets <value>`	Number of vectors to use as test targets.	`100`
`--limit <value>`	Maximum number of nearest vectors to return per query.	`5`
`--kmeans-tree-clusters <value>`	Maximum number of clusters to inspect during search (KMeansTreeSearchTopSize).	`1`
`--recall`	Measure recall of the approximate search compared to exact search.	
`--recall-threads <value>`	Number of concurrent queries during recall measurement.	`10`
`--non-indexed`	Take vector settings from the index, but search without the index (full scan).	
`--stale-ro`	Read with StaleRO consistency mode.	

Warning

Pay attention to the `--kmeans-tree-clusters` parameter — increasing it significantly improves search recall at the expense of speed. Try values from 1 to the number of clusters specified when creating the index.

Common parameters for all load types

Name	Description	Default value
`--dry-run`	Do not execute initialization queries, but only display their text.	
`--check-canonical` or `-c`	Use special version of queries (they have deterministic answers) and compare results with canonical ones.	
`--output <value>`	The name of the file where the query execution results will be saved.	`results.out`
`--iterations <value>`	The number of times each load query will be executed.	`1`
`--json <name>`	The name of the file where query execution statistics will be saved in `json` format.	Not saved by default
`--ministat <name>`	The name of the file where query execution statistics will be saved in `ministat` format.	Not saved by default
`--csv <name>`	The name of the file to save the CSV version of the result table.	Not saved by default
`--plan <name>`	The name of the file to save the query plan. Files like `<name>.<query number>.explain` and `<name>.<query number>.<iteration number>` will be saved in formats: `ast`, `json`, `svg`, and `table`.	Not saved by default
`--query-prefix <setting>`	Query prefix. Every prefix is a line that will be added to the beginning of each query. For multiple prefix lines use this option several times.	Not specified by default
`--retries`	Max retry count for every request.	`0`
`--include`	Names, numbers or ranges of query numbers to be executed as part of the load. Specified as a comma-separated list, e.g.: `1,2,4-6`.	All queries executed
`--exclude`	Names, numbers or ranges of query numbers to be excluded from the load. Specified as a comma-separated list, e.g.: `1,2,4-6`.	None excluded by default
`--verbose` or `-v`	Print additional information to the screen during query execution.	
`--global-timeout <value>`	Global timeout for all queries. Supports time units (e.g., '5s', '1m'). Plain number interpreted as milliseconds.	Not specified by default. The time is unlimited.
`--request-timeout <value>`	Timeout for each iteration of each query. Supports time units (e.g., '5s', '1m'). Plain number interpreted as milliseconds.	Not specified by default. The time is unlimited.
`--threads <value>` or `-t <value>`	The number of parallel threads generating the load. Zero means that queries will be executed in the main thread; otherwise, queries will be mixed.	`0`
`--stats <value>`	Extended execution statistics collection mode. Available values: `full`, `profile`.	`full`

Upsert workload

Continuously inserts new vector rows into the table, generating random embeddings on the fly.

```
ydb workload vector run upsert
```

Available options

Name	Description	Default value
`--table <name>`	Name of the table to insert into.	`vector_index_workload`
`--index <name>`	Name of the vector index.	`index`
`--bulk-size <value>`	Number of rows per upsert batch.	`100`
`--prefixed`	Generate upserts with a `prefix` column (for prefixed indexes).	
`--prefix-count <value>`	Number of distinct prefix values. Used only when `--prefixed` is set.	`1000`

Common parameters for all load types

Name	Description	Default value
`--dry-run`	Do not execute initialization queries, but only display their text.	
`--check-canonical` or `-c`	Use special version of queries (they have deterministic answers) and compare results with canonical ones.	
`--output <value>`	The name of the file where the query execution results will be saved.	`results.out`
`--iterations <value>`	The number of times each load query will be executed.	`1`
`--json <name>`	The name of the file where query execution statistics will be saved in `json` format.	Not saved by default
`--ministat <name>`	The name of the file where query execution statistics will be saved in `ministat` format.	Not saved by default
`--csv <name>`	The name of the file to save the CSV version of the result table.	Not saved by default
`--plan <name>`	The name of the file to save the query plan. Files like `<name>.<query number>.explain` and `<name>.<query number>.<iteration number>` will be saved in formats: `ast`, `json`, `svg`, and `table`.	Not saved by default
`--query-prefix <setting>`	Query prefix. Every prefix is a line that will be added to the beginning of each query. For multiple prefix lines use this option several times.	Not specified by default
`--retries`	Max retry count for every request.	`0`
`--include`	Names, numbers or ranges of query numbers to be executed as part of the load. Specified as a comma-separated list, e.g.: `1,2,4-6`.	All queries executed
`--exclude`	Names, numbers or ranges of query numbers to be excluded from the load. Specified as a comma-separated list, e.g.: `1,2,4-6`.	None excluded by default
`--verbose` or `-v`	Print additional information to the screen during query execution.	
`--global-timeout <value>`	Global timeout for all queries. Supports time units (e.g., '5s', '1m'). Plain number interpreted as milliseconds.	Not specified by default. The time is unlimited.
`--request-timeout <value>`	Timeout for each iteration of each query. Supports time units (e.g., '5s', '1m'). Plain number interpreted as milliseconds.	Not specified by default. The time is unlimited.
`--threads <value>` or `-t <value>`	The number of parallel threads generating the load. Zero means that queries will be executed in the main thread; otherwise, queries will be mixed.	`0`
`--stats <value>`	Extended execution statistics collection mode. Available values: `full`, `profile`.	`full`

Cleaning up

Drop tables created for load testing:

```
ydb workload vector clean
```

Test algorithm

The `run select` mode performs the following stages:

1. A test set is generated:
   - If a table with a test set is specified via `--query-table`, the first `--targets` rows are selected from it in primary key order.
   - Otherwise, `--targets` random rows are selected from the main table.
2. Recall measurement is performed (if `--recall` is specified):

- Two queries are executed for each item in the test set.
- The first query performs an exact vector search (full scan) based on vector distance, forming the `R_exact` result set.
- The second query performs an approximate vector search using the vector index, forming the `R_approx` result set.
- If a filtered vector index is selected, both queries scan only the entries with matching filter column values.
- Recall of the approximate search is calculated using the formula (where `|A|` is the number of elements in the set A and `A ∩ B` is the intersection of sets A and B).

3. Performance measurement is performed:
   - Indexed search queries are run for a specified duration and with a specified number of parallel threads.
   - Each query is executed for a random entry from the test set.
   - The average number of requests per second (RPS) and response time percentiles are calculated.

Usage examples

Example with generated data

1. Initialize the workload table:

```
ydb workload vector init
```

2. Generate and load synthetic vectors:

```
ydb workload vector import generator --rows 100000 --distance cosine
```

3. Run the search workload:

```
ydb workload vector run select --recall
```

   Output example:

```
Recall: 0.8950
Window      Txs Txs/Sec Retries Errors  p50(ms) p95(ms) p99(ms) pMax(ms)
1           100 100     0       0       5       8       12      15
2             98 98     0       0       5       9       13      16
...

Total       Txs Txs/Sec Retries Errors  p50(ms) p95(ms) p99(ms) pMax(ms)
10          980 98.0    0       0       5       9       14      18
```

   Column descriptions:

   - `Window` — Sequential number of the time window (e.g., each second or fixed interval).
   - `Txs` — Number of transactions successfully completed in this window (or total across all windows in the bottom section).
   - `Txs/Sec` — Transaction rate per second for the given window (or average for total).
   - `Retries` — Number of automatic retries performed due to temporary errors (e.g., conflicts or throttling).
   - `Errors` — Number of unrecoverable errors encountered.
   - `p50(ms)` — Median (50th percentile) transaction latency in milliseconds.
   - `p95(ms)` — 95th percentile latency (milliseconds).
   - `p99(ms)` — 99th percentile latency (milliseconds).
   - `pMax(ms)` — Maximum observed latency within the window (or overall maximum for total).

4. Run the upsert workload:

```
ydb workload vector run upsert
```

5. Clean up:

```
ydb workload vector clean
```

Example with an external dataset

1. Prepare tables and load data. See the recipe Vector index with external dataset loading.

   Examples of creating vector indexes are available on the Vector Indexes documentation page.

2. Run the search workload:

```
ydb -e grpc://hostname:2135 -d /Root/testdb workload vector run select \
    --table wikipedia --index idx_vector \
    --query-table wikipedia_sample --recall
```

   Output example:

```
Recall: 0.8950
Window      Txs Txs/Sec Retries Errors  p50(ms) p95(ms) p99(ms) pMax(ms)
1           100 100     0       0       5       8       12      15
2             98 98     0       0       5       9       13      16
...

Total       Txs Txs/Sec Retries Errors  p50(ms) p95(ms) p99(ms) pMax(ms)
10          980 98.0    0       0       5       9       14      18
```

Remarks

- The search workload generates SQL queries that select nearest rows by vector distance from table `--table` using index `--index`.
- You don't need to specify column names (embedding, filter, primary key columns) or the distance function — they are automatically extracted from the index definition.
- Random selection of test vectors from `--table` works only if its primary key is numeric.
- If `--query-table` is specified, it must have the same vector and filter column names as `--table`.
- Recall measurement (`--recall`) is performed as a separate stage before the main performance test and shows the average overlap ratio (from 0 to 1) of indexed search results with full-scan search results across all selected test vectors.

Preparing a test sample from a large table

> **Warning**
>
> This step is only required if you don't already have a test dataset and if the primary key of the main table isn't numeric, because auto-generation of the test set doesn't work for non-numeric keys.

In this case, you can prepare a test set by selecting random rows from the main table manually. Example query to create the table for test samples:

```
CREATE TABLE vector_index_sample (
    id Uint64 NOT NULL,
    prefix Uint64 NOT NULL,
    embedding String NOT NULL,
    PRIMARY KEY (id)
);
```

A query to fill it with approximately 1000 rows from a large table:

```
INSERT INTO vector_index_sample
SELECT id, prefix, embedding FROM large_table
WHERE RandomNumber(id) < 0xFFFFFFFFFFFFFFFF / <number_of_rows_in_table> * 1000;
```

> **Tip**
>
> You can find the approximate number of rows in the table in table statistics without running `SELECT COUNT(*)`.

Managing YDB configuration

> **Note**
>
> Before YDB CLI 2.20.0, the `ydb admin cluster config` commands had the following format: `ydb admin config`.

This section contains commands for managing the YDB cluster configuration.

- Apply the `dynconfig.yaml` configuration to the cluster:

```
ydb admin cluster config replace -f dynconfig.yaml
```

- Check if it is possible to apply the configuration dynconfig.yaml to the cluster (check all validators, the configuration version in the yaml file must be 1 higher than the cluster configuration version, the cluster name must match):

```
ydb admin cluster config replace -f dynconfig.yaml --dry-run
```

- Apply the `dynconfig.yaml` configuration to the cluster, ignoring version and cluster checks (the version and cluster values will be overwritten with correct values):

```
ydb admin cluster config replace -f dynconfig.yaml --force
```

- Fetch the main cluster configuration:

```
ydb admin cluster config fetch
```

- Generate all possible final configurations for `dynconfig.yaml`:

```
ydb admin cluster config resolve --all -f dynconfig.yaml
```

- Generate the final configuration for `dynconfig.yaml` with the `tenant=/Root/test` and `canary=true` labels:

```
ydb admin cluster config resolve -f dynconfig.yaml --label tenant=/Root/test --label canary=true
```

- Generate the final configuration for `dynconfig.yaml` for labels from node 100:

```
ydb admin cluster config resolve -f dynconfig.yaml --node-id 100
```

- Generate a dynamic configuration file, based on a static configuration on the cluster:

```
ydb admin cluster config genereate
```

- Initialize a directory with the configuration, using the path to the configuration file:

```
ydb admin node config init --config-dir <path_to_directory> --from-config <path_to_configuration_file>
```

- Initialize a directory with the configuration, using the configuration from the cluster:

```
ydb admin node config init --config-dir <path_to_directory> --seed-node <cluster_node_endpoint>
```

Managing temporary configuration

This section contains commands for managing temporary configurations.

- Fetch all temporary configurations from the cluster:

```
ydb admin volatile-config fetch --all --output-directory <dir>
```

- Fetch the temporary configuration with id 1 from the cluster:

```
ydb admin volatile-config fetch --id 1
```

- Apply the `volatile.yaml` temporary configuration to the cluster:

```
ydb admin volatile-config add -f volatile.yaml
```

- Delete temporary configurations with ids 1 and 3 on the cluster:

```
ydb admin volatile-config drop --id 1 --id 3
```

- Delete all temporary configurations on the cluster:

```
ydb admin volatile-config drop --all
```

Parameters

- `-f, --filename <filename.yaml>` — read input from a file, `-` for STDIN. For commands that accept multiple files (e.g., resolve), you can specify it multiple times, the file type will be determined by the metadata field
- `--output-directory <dir>` — dump/resolve files to a directory
- `--strip-metadata` — remove the metadata field from the output
- `--all` — extends the output of commands to the entire configuration (see advanced configuration)
- `--allow-unknown-fields` — allows ignoring unknown fields in the configuration

Scenarios

Update the main cluster configuration

```
# Fetch the cluster configuration
ydb admin cluster config fetch > dynconfig.yaml
# Edit the configuration with your favorite editor
vim dynconfig.yaml
# Apply the configuration dynconfig.yaml to the cluster
ydb admin cluster config replace -f dynconfig.yaml
```

Similarly, in one line:

```
ydb admin cluster config fetch | yq '.config.actor_system_config.scheduler.resolution = 128' | ydb admin clus
ter config replace -f -
```

Command output:

```
OK
```

View the configuration for a specific set of labels

```
ydb admin cluster config resolve --remote --label tenant=/Root/db1 --label canary=true
```

Command output:

```
---
label_sets:
- dynamic:
    type: COMMON
    value: true
config:
  actor_system_config:
    use_auto_config: true
    node_type: COMPUTE
    cpu_count: 4
```

View the configuration for a specific node

```
ydb admin cluster config resolve --remote --node-id <node_id>
```

Command output:

```
---
label_sets:
- dynamic:
    type: COMMON
    value: true
config:
  actor_system_config:
    use_auto_config: true
    node_type: COMPUTE
    cpu_count: 4
```

Save all configurations locally

```
ydb admin cluster config fetch --all --output-directory <configs_dir>
ls <configs_dir>
```

Command output:

```
dynconfig.yaml volatile_1.yaml volatile_3.yaml
```

View all configurations locally

```
ydb admin cluster config fetch --all
```

Command output:

```
---
metadata:
  kind: main
  cluster: unknown
  version: 1
config:
  actor_system_config:
    use_auto_config: true
    node_type: COMPUTE
    cpu_count: 4
allowed_labels: {}
selector_config: []
---
metadata:
  kind: volatile
  cluster: unknown
  version: 1
  id: 1
# some comment example
selectors:
- description: test
  selector:
    tenant: /Root/db1
  config:
    actor_system_config: !inherit
      use_auto_config: true
      cpu_count: 12
```

View the final configuration for a specific node from the locally saved original configuration

```
ydb admin cluster config resolve -k <configs_dir> --node-id <node_id>
```

Command output:

```
---
label_sets:
- dynamic:
    type: COMMON
    value: true
config:
  actor_system_config:
    use_auto_config: true
    node_type: COMPUTE
    cpu_count: 4
```

Configuration Management

The YDB CLI provides commands for managing the dynamic configuration at different levels of the system.

General command syntax:

```
ydb [global options...] admin [scope] config [subcommands...]
```

- `global options` — Global parameters.
- `scope` — Configuration scope (`cluster`, `node`).
- `subcommands` — Subcommands for managing configuration.

View the command description:

```
ydb admin --help
```

Available Configuration Scopes

Cluster Configuration

Managing cluster-level configuration:

```
ydb admin cluster config [subcommands...]
```

Available subcommands:

- fetch - Fetches the current dynamic cluster configuration.
- generate - Generates dynamic configuration based on the static configuration on the cluster.
- replace - Replaces the dynamic configuration.
- version - Show configuration version on nodes (V1/V2).

Node Configuration

Managing node-level configuration:

```
ydb admin node config [subcommands...]
```

Available subcommands:

- init - Initializes the directory for node configuration.

Cluster Configuration Management Commands

Cluster configuration management commands are designed for working with the configuration at the level of the entire YDB cluster. These commands allow cluster administrators to view, modify, and manage settings that apply to all cluster nodes.

> **Alert**
>
> Commands in this section can harm your cluster if used incorrectly. Due to the potentially dangerous nature of these commands, ALL global parameters must be specified explicitly. Profiles are disabled by default and are only used when explicitly specified (--profile). Some commands do not require global options that are otherwise mandatory.

General syntax for calling cluster configuration management commands:

```
ydb [global options] admin cluster config [command options] <subcommand>
```

Where:

- `ydb` – The command to run the YDB CLI from the operating system command line.
- `[global options]` – Global options, common to all YDB CLI commands.
- `admin cluster config` – The command for managing cluster configuration.
- `[command options]` – Command options specific to each command and subcommand.
- `<subcommand>` – The subcommand.

Commands

The following is a list of available subcommands for managing cluster configuration. Any command can be called from the command line with the `--help` option to get help for it.

Command / Subcommand	Brief Description
admin cluster config fetch	Fetch the current dynamic configuration (aliases: `get`, `dump`)
admin cluster config generate	Generate dynamic configuration from the static startup configuration
admin cluster config replace	Replace the dynamic configuration
admin cluster config vesion	Show configuration version on nodes (V1/V2)

admin cluster config generate

With the `admin cluster config generate` command, you can generate a dynamic configuration file based on the static configuration file on the YDB cluster.
The dynamic configuration uses the format of an extended static configuration; the command automates the conversion process.

General command syntax:

```
ydb [global options...] admin cluster config generate
```

- `global options` — Global parameters.

View the description of the dynamic configuration generation command:

```
ydb admin cluster config generate --help
```

Examples

Generate the dynamic configuration based on the static configuration:

```
ydb admin cluster config generate > config.yaml
```

After executing this command, the `config.yaml` file will contain a YAML document in the following format:

```
metadata:
  kind: MainConfig
  cluster: ""
  version: 0
config:
  <static cluster configuration>
```

Using the Generated Dynamic Configuration

After generating the dynamic configuration, you can perform the following steps:

1. Add configuration parameters to the dynamic configuration file.
2. Apply the dynamic configuration to the cluster using the `admin cluster config replace` command.

admin cluster config fetch

With the `admin cluster config fetch` command, you can retrieve the current dynamic configuration of the YDB cluster.

General command syntax:

```
ydb [global options...] admin cluster config fetch
```

- `global options` — Global parameters.

View the description of the dynamic configuration fetch command:

```
ydb admin cluster config fetch --help
```

Examples

Fetch the current dynamic configuration of the cluster:

```
ydb --endpoint grpc://localhost:2135 admin cluster config fetch > config.yaml
```

admin cluster config replace

With the `admin cluster config replace` command, you can upload a dynamic configuration to the YDB cluster.

> **Alert**
>
> Commands in this section can harm your cluster if used incorrectly. Due to the potentially dangerous nature of these commands, ALL global parameters must be specified explicitly. Profiles are disabled by default and are only used when explicitly specified (--profile). Some commands do not require global options that are otherwise mandatory.

General command syntax:

```
ydb [global options...] admin cluster config replace [options...]
```

- `global options` — Global parameters.
- `options` — Subcommand parameters.

View the description of the dynamic configuration replacement command:

```
ydb admin cluster config replace --help
```

Subcommand Parameters

Name	Description
`-f`, `--filename`	Path to the file containing the configuration.
`--allow-unknown-fields`	Allow unknown fields in the configuration. If the flag is not set, unknown fields in the configuration result in an error.
`--ignore-local-validation`	Ignore basic client-side configuration validation. If the flag is not set, YDB CLI performs basic client-side configuration validation.

Examples

Upload the dynamic configuration file to the cluster:

```
ydb admin cluster config replace --filename config.yaml
```

Upload the dynamic configuration file to the cluster, ignoring local applicability checks:

```
ydb admin cluster config replace -f config.yaml --ignore-local-validation
```

Upload the dynamic configuration file to the cluster, ignoring the check for unknown fields:

```
ydb admin cluster config replace -f config.yaml --allow-unknown-fields
```

Node Configuration Management Commands

Node configuration management commands are designed for working with the configuration at the level of individual YDB cluster nodes. These commands allow cluster administrators to initialize, update, and manage the settings of individual nodes.

> **Alert**
>
> Commands in this section can harm your cluster if used incorrectly. Due to the potentially dangerous nature of these commands, ALL global parameters must be specified explicitly. Profiles are disabled by default and are only used when explicitly specified (--profile). Some commands do not require global options that are otherwise mandatory.

General syntax for calling node configuration management commands:

```
ydb [global options] admin node config [command options] <subcommand>
```

- `ydb` – The command to run the YDB CLI from the operating system command line.
- `[global options]` – Global options, common to all YDB CLI commands.
- `admin node config` – The command for managing node configuration.
- `[command options]` – Command options specific to each command and subcommand.
- `<subcommand>` – The subcommand.

Commands

The following is a list of available subcommands for managing node configuration. Any command can be called from the command line with the `--help` option to get help for it.

Command / Subcommand	Brief Description
admin node config init	Initialize the directory for node configuration

admin node config init

When deploying a new YDB cluster or adding nodes to an existing one (scaling out), each node requires a directory to store its configuration. The `admin node config init` command creates and prepares this directory by placing a specified configuration file in it or retrieving the configuration from another cluster node (seed node).

General command syntax:

```
ydb [global options...] admin node config init [options...]
```

- `global options` — Global parameters.
- `options` — Subcommand parameters.

View the description of the node configuration initialization command:

```
ydb admin node config init --help
```

Subcommand Parameters

Name	Description
`-d`, `--config-dir`	**Required**. Path to the directory for storing the configuration file.
`-f`, `--from-config`	Path to the initial configuration file. Required for initial cluster deployment. Can also be used for scaling out if a file with the current cluster configuration has been delivered to the node beforehand.
`-s`, `--seed-node`	Endpoint of the source node (seed node) from which the configuration will be retrieved. Used for scaling out the cluster.

Examples

Initialize the node's configuration directory using the specified configuration file:

```
ydb admin node config init --config-dir /opt/ydb/cfg-dir --from-config config.yaml
```

Initialize the node's configuration by retrieving it from a source node:

```
ydb admin node config init --config-dir /opt/ydb/cfg-dir --seed-node <node.ydb.tech>:2135
```

Usage

After successfully initializing the node's configuration directory, you can start the `ydbd` process on this node by adding the `--config-dir` parameter specifying the path to the directory. From this point on, when the cluster configuration is updated, the system automatically saves the updated config to the specified directory, eliminating the need to manually update the configuration file on the node.

When the node restarts, it automatically loads the current configuration from this directory.

Bridge cluster management commands

Feature of Yandex Enterprise Database

This functionality is available only in the Yandex Enterprise Database. In the open-source version of YDB it is absent.

Commands for managing the cluster in bridge mode let you view pile state, perform planned and emergency PRIMARY change, temporarily take a pile out for maintenance, and return it to the cluster.

Alert

Commands in this section can harm your cluster if used incorrectly. Due to the potentially dangerous nature of these commands, **ALL** global parameters must be specified explicitly. Profiles are disabled by default and are only used when explicitly specified (`--profile <profile-name>`). Some commands do not require global options that are otherwise mandatory.

General syntax for bridge cluster management commands:

```
ydb [global options...] admin cluster bridge [command options...] <subcommand>
```

where:

- `ydb` — command to launch YDB CLI from the operating system command line;
- `[global options]` — global parameters common to all YDB CLI commands;
- `admin cluster bridge` — cluster configuration management command;
- `[command options]` — parameters specific to each command and subcommand;
- `<subcommand>` — subcommand.

Commands

Below is the list of available subcommands for bridge cluster management. You can run any command with the `--help` option for help.

Command / subcommand	Brief description
admin cluster bridge list	List pile state
admin cluster bridge switchover	Planned PRIMARY change
admin cluster bridge failover	Emergency failover
admin cluster bridge takedown	Take pile out of cluster
admin cluster bridge rejoin	Return pile to cluster

admin cluster bridge list

> **Feature of Yandex Enterprise Database**
>
> This functionality is available only in the Yandex Enterprise Database. In the open-source version of YDB it is absent.

Use the `admin cluster bridge list` command to list the state of each pile in bridge mode.

General command syntax:

```
ydb [global options...] admin cluster bridge list [options...]
```

- `global options` — global parameters for the CLI.
- `options` — subcommand parameters.

View command help:

```
ydb admin cluster bridge list --help
```

Subcommand parameters

Name	Description
`--format <pretty, json, csv>`	Output format. Valid values: `pretty`, `json`, `csv`. Default: `pretty`.

Examples

List piles in human-readable format:

```
ydb admin cluster bridge list

pile-a: PRIMARY
pile-b: SYNCHRONIZED
```

Output state in JSON format:

```
ydb admin cluster bridge list --format json

{
  "pile-a": "PRIMARY",
  "pile-b": "SYNCHRONIZED"
}
```

Output state in CSV format:

```
ydb admin cluster bridge list --format csv

pile,state
pile-a,PRIMARY
pile-b,SYNCHRONIZED
```

admin cluster bridge switchover

> **Feature of Yandex Enterprise Database**
>
> This functionality is available only in the Yandex Enterprise Database. In the open-source version of YDB it is absent.

Use the `admin cluster bridge switchover` command to perform a smooth, planned transition of the specified pile to `PRIMARY` via the intermediate `PROMOTED` state. For details, see the scenario description.

> **Alert**
>
> Commands in this section can harm your cluster if used incorrectly. Due to the potentially dangerous nature of these commands, **ALL** global parameters must be specified explicitly. Profiles are disabled by default and are only used when explicitly specified (`--profile <profile-name>`). Some commands do not require global options that are otherwise mandatory.

General command syntax:

```
ydb [global options...] admin cluster bridge switchover [options...]
```

- `global options` — global parameters for the CLI.
- `options` — subcommand parameters.

View command help:

```
ydb admin cluster bridge switchover --help
```

Subcommand parameters

Name	Description
`--new-primary <pile>`	Name of the pile that should become the new PRIMARY.

Requirements

- The target pile must be in the `SYNCHRONIZED` state.

Examples

Transition pile `pile-b` from `SYNCHRONIZED` to `PRIMARY` via the intermediate `PROMOTED` state:

```
ydb admin cluster bridge switchover --new-primary pile-b
```

Verifying the result

After a short time (a few minutes), verify that pile states have changed correctly using the list command:

```
ydb admin cluster bridge list

pile-a: SYNCHRONIZED
pile-b: PRIMARY
```

admin cluster bridge failover

Feature of Yandex Enterprise Database

This functionality is available only in the Yandex Enterprise Database. In the open-source version of YDB it is absent.

Use the `admin cluster bridge failover` command to perform emergency disable of a pile when it is unavailable. You can optionally specify the pile that will become the new `PRIMARY`.

Alert

Commands in this section can harm your cluster if used incorrectly. Due to the potentially dangerous nature of these commands, **ALL** global parameters must be specified explicitly. Profiles are disabled by default and are only used when explicitly specified (`--profile <profile-name>`). Some commands do not require global options that are otherwise mandatory.

General command syntax:

```
ydb [global options...] admin cluster bridge failover [options...]
```

- `global options` — global parameters for the CLI.
- `options` — subcommand parameters.

View command help:

```
ydb admin cluster bridge failover --help
```

Subcommand parameters

Name	Description
`--pile <pile>`	Name of the unavailable pile.
`--new-primary <pile>`	Name of the pile that should become the new `PRIMARY`. Specify if the unavailable pile was `PRIMARY`.

Requirements

- If the current `PRIMARY` is unavailable, you must specify `--new-primary` and choose a pile in the `SYNCHRONIZED` state. If `--new-primary` is missing or the chosen pile is not in `SYNCHRONIZED` state, the command returns an error without making any changes.
- The cluster will not enter an invalid state: if requirements are violated, the command makes no changes and reports an error.
- If the pile has not failed but you need to disable it, use planned disable — the `takedown` command.
- The command requires cluster administrator privileges. If mandatory authentication is enabled, login and password authentication cannot be used while the cluster is in an emergency state — use client certificate authentication instead. For details, see Authentication specifics when the cluster is in an emergency state.

Examples

Perform emergency disable for an unavailable pile named `pile-a`:

```
ydb admin cluster bridge failover --pile pile-a
```

Perform emergency disable for an unavailable `PRIMARY` pile and designate a synchronized pile as the new `PRIMARY`:

```
ydb admin cluster bridge failover --pile pile-a --new-primary pile-b
```

Verifying the result

Use the list command to verify that the unavailable pile has been moved to `DISCONNECTED` and (if `--new-primary` was specified) a new `PRIMARY` has been selected:

```
ydb admin cluster bridge list

pile-a: DISCONNECTED
pile-b: PRIMARY
```

admin cluster bridge takedown

> **Feature of Yandex Enterprise Database**
>
> This functionality is available only in the Yandex Enterprise Database. In the open-source version of YDB it is absent.

Use the `admin cluster bridge takedown` command to perform planned disable of a pile. If you are disabling the current `PRIMARY`, you must specify the new `PRIMARY`.

> **Alert**
>
> Commands in this section can harm your cluster if used incorrectly. Due to the potentially dangerous nature of these commands, **ALL** global parameters must be specified explicitly. Profiles are disabled by default and are only used when explicitly specified (`--profile <profile-name>`). Some commands do not require global options that are otherwise mandatory.

General command syntax:

```
ydb [global options...] admin cluster bridge takedown [options...]
```

- `global options` — global parameters.
- `options` — subcommand parameters.

View command help:

```
ydb admin cluster bridge takedown --help
```

Subcommand parameters

Name	Description
`--pile <pile>`	Name of the pile to take out of the cluster.
`--new-primary <pile>`	Name of the pile that should become the new `PRIMARY` if the current `PRIMARY` is being disabled.

Requirements

- If you are disabling the current `PRIMARY`, you must specify `--new-primary` and choose a pile in the `SYNCHRONIZED` state.

Examples

Take `SYNCHRONIZED` pile `pile-b` out of the cluster:

```
ydb admin cluster bridge takedown --pile pile-b
```

Take `PRIMARY` pile `pile-a` out of the cluster and transition `pile-b` from `SYNCHRONIZED` to `PRIMARY`:

```
ydb admin cluster bridge takedown --pile pile-a --new-primary pile-b
```

Verifying the result

Verify the resulting pile states with the list command:

```
ydb admin cluster bridge list

pile-a: PRIMARY
pile-b: DISCONNECTED
```

If you disabled the current `PRIMARY` with `--new-primary`, verify that the chosen pile has become `PRIMARY`:

```
ydb admin cluster bridge list

pile-a: DISCONNECTED
pile-b: PRIMARY
```

admin cluster bridge rejoin

Feature of Yandex Enterprise Database

This functionality is available only in the Yandex Enterprise Database. In the open-source version of YDB it is absent.

Use the `admin cluster bridge rejoin` command to return the specified pile to the cluster after maintenance or recovery. After the command runs, the pile is expected to transition from `DISCONNECTED` to `NOT_SYNCHRONIZED`, then sync automatically and transition to `SYNCHRONIZED`.

Alert

Commands in this section can harm your cluster if used incorrectly. Due to the potentially dangerous nature of these commands, **ALL** global parameters must be specified explicitly. Profiles are disabled by default and are only used when explicitly specified (`--profile <profile-name>`). Some commands do not require global options that are otherwise mandatory.

General command syntax:

```
ydb [global options...] admin cluster bridge rejoin [options...]
```

- `global options` — global parameters.
- `options` — subcommand parameters.

View command help:

```
ydb admin cluster bridge rejoin --help
```

Subcommand parameters

Name	Description
`--pile <pile>`	Name of the pile to return to the cluster.

Requirements

- The pile must be in the `DISCONNECTED` state before it can be returned.

Examples

Return pile `pile-a` from `DISCONNECTED` state:

```
ydb admin cluster bridge rejoin --pile pile-a
```

Verifying the result

Right after the command runs, the pile is expected to transition to `NOT_SYNCHRONIZED`. Verify with the list command:

```
ydb admin cluster bridge list

pile-a: NOT_SYNCHRONIZED
pile-b: PRIMARY
```

After synchronization completes, the pile transitions to `SYNCHRONIZED`:

```
ydb admin cluster bridge list

pile-a: SYNCHRONIZED
pile-b: PRIMARY
```

Reference for YDB SDK

To work with YDB, OpenSource SDKs are available for the following programming languages:

Language	GitHub Repository	API Reference
Go	ydb-platform/ydb-go-sdk	https://pkg.go.dev/github.com/ydb-platform/ydb-go-sdk/v3
Java	ydb-platform/ydb-java-sdk	N/A
Python	ydb-platform/ydb-python-sdk	https://ydb-platform.github.io/ydb-python-sdk
C#	ydb-platform/ydb-dotnet-sdk	N/A
JavaScript	ydb-platform/ydb-js-sdk	https://ydb.js.org
Rust	ydb-platform/ydb-rs-sdk	N/A
C++	ydb-platform/ydb-cpp-sdk	N/A
PHP	ydb-platform/ydb-php-sdk	N/A

The SDK documentation contains the following sections:

- Installation
- Authentication
- Handling errors
- SDK feature comparison
- Parameterized queries
- Data formats
- Working with topics
- Working with coordination nodes
- Observability in YDB SDK

See also:

- Documentation for application developers
- Test applications
- Code recipes
- Generate code from YQL

Reference for YDB SDK

To work with YDB, OpenSource SDKs are available for the following programming languages:

Language	GitHub Repository	API Reference
Go	ydb-platform/ydb-go-sdk	https://pkg.go.dev/github.com/ydb-platform/ydb-go-sdk/v3
Java	ydb-platform/ydb-java-sdk	N/A
Python	ydb-platform/ydb-python-sdk	https://ydb-platform.github.io/ydb-python-sdk
C#	ydb-platform/ydb-dotnet-sdk	N/A
JavaScript	ydb-platform/ydb-js-sdk	https://ydb.js.org
Rust	ydb-platform/ydb-rs-sdk	N/A
C++	ydb-platform/ydb-cpp-sdk	N/A
PHP	ydb-platform/ydb-php-sdk	N/A

The SDK documentation contains the following sections:

- Installation

Installing the YDB SDK

Follow the instructions below to quickly install the OpenSource SDK. Make sure to preinstall and configure tools for working with the selected programming language and package managers on your workstation.

The build process using the source code is described in the source code repositories on GitHub. Follow the links given on the YDB SDK - Overview page.

Go

Run the command from the command line:

```
go get -u github.com/ydb-platform/ydb-go-sdk/v3
```

To ensure that the installation is successful, make sure that your environment is running Go 1.17 or higher.

Java

Add dependencies to the Maven project as described in the "Install the SDK" step of the `readme.md` file in the source code repository.

Python

Run the command from the command line:

```
python3 -m pip install ydb
```

If the command fails, make sure your environment has Python 3.8 or newer installed with the pip package manager enabled.

C# (.NET)

```
dotnet add package Ydb.Sdk
```

JavaScript

```
npm install @ydbjs/core @ydbjs/query
```

The minimum supported Node.js® version is 20.19.

Rust

Add to Cargo.toml last version of ydb crate.

C++

Debian packages (Ubuntu 24.04)

Pre-built `.deb` packages for Ubuntu 24.04 (Noble), amd64 are attached to each GitHub release. Download and install them locally:

```
# Replace <TAG> with a release tag from GitHub releases
TAG=<TAG>
BASE="https://github.com/ydb-platform/ydb-cpp-sdk/releases/download/${TAG}"

wget "${BASE}/yandex-googleapis-api-common-protos-1.0.0-Linux.deb"
wget "${BASE}/libydb-cpp-dev_${TAG#v}_amd64.deb"
# Optional plugins:
wget "${BASE}/libydb-cpp-iam-dev_${TAG#v}_amd64.deb"
wget "${BASE}/libydb-cpp-otel-metrics-dev_${TAG#v}_amd64.deb"
wget "${BASE}/libydb-cpp-otel-tracing-dev_${TAG#v}_amd64.deb"

sudo apt-get update
sudo apt-get install -y \
    ./yandex-googleapis-api-common-protos-*.deb \
    ./libydb-cpp-dev_*.deb ./libydb-cpp-iam-dev_*.deb \
    ./libydb-cpp-otel-metrics-dev_*.deb ./libydb-cpp-otel-tracing-dev_*.deb
```

Available packages:

- `yandex-googleapis-api-common-protos` — required protobuf dependency;
- `libydb-cpp-dev` — core SDK: static library, public headers, and CMake package files;
- `libydb-cpp-iam-dev` — IAM credentials plugin (optional);
- `libydb-cpp-otel-metrics-dev` — OpenTelemetry metrics plugin (optional);
- `libydb-cpp-otel-tracing-dev` — OpenTelemetry tracing plugin (optional; requires `libydb-cpp-otel-metrics-dev` for OTel headers and libraries).

Note

- Supported platform: Ubuntu 24.04 (Noble), amd64.
- The `.deb` packages do not declare apt dependencies on each other; install `yandex-googleapis-api-common-protos` together with the core SDK package.
- For other platforms, use the build-from-source instructions below.

Using the SDK in CMake

After installing the packages, use the SDK in your CMake project:

```
find_package(ydb-cpp-sdk REQUIRED COMPONENTS Driver Table Topic)
target_link_libraries(myapp PRIVATE YDB-CPP-SDK::Driver YDB-CPP-SDK::Table)
```

Pass `-DCMAKE_PREFIX_PATH=/usr/share/yandex` when configuring your project, since the packages install under the Yandex prefix.

Build from source

Clone the ydb-cpp-sdk repository and run the following commands from the command line:

```
cmake --preset release-${compiler} -D YDB_SDK_INSTALL=On
cmake --build --preset default
cmake --install build --prefix ${ydb_install_dir}
```

- `compiler` — your compiler (`clang` or `gcc`);
- `ydb_install_dir` — the path where you want to install the SDK.

Make sure all dependencies are installed before running the commands. See the README in the source repository for the full list of build dependencies and instructions.

PHP

```
composer require ydb-platform/ydb-php-sdk
```

Authentication in the SDK

As we discussed in the YDB server connection article, the client must add an authentication token to each request. The authentication token is checked by the server. If the authentication is successful, the request is authorized and executed. Otherwise, the `Unauthenticated` error returns.

The YDB SDK uses an object that is responsible for generating these tokens. SDK provides built-in methods for getting such an object:

1. The methods that pass parameters explicitly, with each method implementing a certain authentication mode.
2. The method that determines the authentication mode and relevant parameters based on environmental variables.

Usually, you create a token generation object before you initialize the YDB driver, and you pass the object to the driver constructor as a parameter. The C++ and Go SDKs additionally let you work with multiple databases and token generation objects through a single driver.

If the token generation object is not defined, the driver won't add any authentication data to the requests. This approach enables you to successfully connect to locally deployed YDB clusters without enabling mandatory authentication. If you enable mandatory authentication, database requests without an authentication token will be rejected with an authentication error.

Methods for creating token generation objects

You can click any of the methods below to go to the source code of an example in the repository. You can also learn about the authentication code recipes.

Python

Mode	Method
Anonymous	ydb.AnonymousCredentials()
Access Token	ydb.AccessTokenCredentials(token)
Metadata	ydb.iam.MetadataUrlCredentials()
Service Account Key	ydb.iam.ServiceAccountCredentials.from_file(key_file, iam_endpoint=None, iam_channel_credentials=None)
Static Credentials	ydb.StaticCredentials.from_user_password(user, password)
OAuth 2.0 token exchange	ydb.oauth2_token_exchange.Oauth2TokenExchangeCredentials(), ydb.oauth2_token_exchange.Oauth2TokenExchangeCredentials.from_file(cfg_file, iam_endpoint=None)
Determined by environment variables	`ydb.credentials_from_env_variables()`

Go

Mode	Package	Method
Anonymous	ydb-go-sdk/v3	ydb.WithAnonymousCredentials()
Access Token	ydb-go-sdk/v3	ydb.WithAccessTokenCredentials(token)
Metadata	ydb-go-yc	yc.WithMetadataCredentials(ctx)
Service Account Key	ydb-go-yc	yc.WithServiceAccountKeyFileCredentials(key_file)
Static Credentials	ydb-go-sdk/v3	ydb.WithStaticCredentials(user, password)
OAuth 2.0 token exchange	ydb-go-sdk/v3	ydb.WithOauth2TokenExchangeCredentials(options...), ydb.WithOauth2TokenExchangeCredentialsFile(configFilePath)
Determined by environment variables	ydb-go-sdk-auth-environ	environ.WithEnvironCredentials(ctx)

Java

Mode	Method
Anonymous	tech.ydb.core.auth.NopAuthProvider.INSTANCE
Access Token	new tech.ydb.core.auth.TokenAuthProvider(accessToken);
Metadata	tech.ydb.auth.iam.CloudAuthHelper.getMetadataAuthProvider();
Service Account Key	tech.ydb.auth.iam.CloudAuthHelper.getServiceAccountFileAuthProvider(saKeyFile);
OAuth 2.0 token exchange	tech.ydb.auth.OAuth2TokenExchangeProvider.fromFile(cfgFile);
Determined by environment variables	tech.ydb.auth.iam.CloudAuthHelper.getAuthProviderFromEnviron();

JavaScript

Mode	Method
Anonymous	AnonymousCredentialsProvider()
Access Token	AccessTokenCredentialsProvider({ token })
Metadata	MetadataCredentialsProvider()

Service Account Key	ServiceAccountCredentialsProvider.fromFile(saKeyFile)
Static Credentials	StaticCredentialsProvider({ username, password }, endpoint)
Determined by environment variables	EnvironCredentialsProvider(connectionString)

Rust

Mode	Method
Anonymous	ydb::AnonymousCredentials or ydb::AccessTokenCredentials::from("")
Access Token	ydb::AccessTokenCredentials::from("token")
Metadata	ydb::MetadataUrlCredentials
Service Account Key	ydb::ServiceAccountCredentials
Static Credentials	ydb::StaticCredentialsAuth
Determined by environment variables	ydb::FromEnvCredentials
Execution of an external command	ydb::CommandLineCredentials (for example, for authentication using a Yandex.Cloud IAM token from the developer's computer `ydb::CommandLineCredentials::from_cmd("yc iam create-token")`)

PHP

Mode	Method
Anonymous	AnonymousAuthentication()
Access Token	AccessTokenAuthentication($accessToken)
Oauth Token	OAuthTokenAuthentication($oauthToken)
Metadata	MetadataAuthentication()
Service Account Key	JwtWithJsonAuthentication(key_id, $service_account_id, $privateKeyFile)
Determined by environment variables	EnvironCredentials()
Static Credentials	StaticAuthentication($user, $password)

Procedure for determining the authentication mode and parameters from the environment

The following algorithm that is the same for all SDKs applies:

1. If the value of the `YDB_SERVICE_ACCOUNT_KEY_FILE_CREDENTIALS` environment variable is set, the **System Account Key** authentication mode is used and the key is taken from the file whose name is specified in this variable.
2. Otherwise, if the value of the `YDB_ANONYMOUS_CREDENTIALS` environment variable is set to 1, the anonymous authentication mode is used.
3. Otherwise, if the value of the `YDB_METADATA_CREDENTIALS` environment variable is set to 1, the **Metadata** authentication mode is used.
4. Otherwise, if the value of the `YDB_ACCESS_TOKEN_CREDENTIALS` environment variable is set, the **Access token** authentication mode is used, where the this variable value is passed.
5. Otherwise, if the value of the `YDB_OAUTH2_KEY_FILE` environment variable is set, the **OAuth 2.0 token exchange** authentication mode is used, and the parameters are taken from the JSON file specified in this variable.
6. Otherwise, the **Metadata** authentication mode is used.

If the last step of the algorithm is selecting the **Metadata** mode, you can deploy a working application on VMs and in Yandex.Cloud Cloud Functions without setting any environment variables.

File format for OAuth 2.0 token exchange authentication mode parameters

Description of fields of JSON file with **OAuth 2.0 token exchange** authentication mode parameters. The set of fields depends on the original token type, `JWT` and `FIXED`.

In the table below, `creds_json` means a JSON with parameters for exchanging the original token for an access token.

Fields not described in this table are ignored.

Field	Type	Description	Default value/optionality
`grant-type`	string	Grant type	`urn:ietf:params:oauth:grant-type:token-exchange`
`res`	string | list of strings	Resource	optional
`aud`	string | list of strings	Audience option for token exchange request	optional
`scope`	string | list of strings	Scope	optional
`requested-token-type`	string	Requested token type	`urn:ietf:params:oauth:token-type:access_token`
`subject-credentials`	creds_json	Subject credentials	optional

`actor-credentials`	creds_json	Actor credentials	optional
`token-endpoint`	string	Token endpoint. In the case of YDB CLI, it is overridden by the `--iam-endpoint` option.	optional
Description of fields of `creds_json` (JWT)			
`type`	string	Token source type. Set `JWT`	
`alg`	string	Algorithm for JWT signature. Supported algorithms: ES256, ES384, ES512, HS256, HS384, HS512, PS256, PS384, PS512, RS256, RS384, RS512	
`private-key`	string	(Private) key in PEM format (for algorithms `ES*`, `PS*`, `RS*`) or Base64 format (for algorithms `HS*`) for JWT signature	
`kid`	string	`kid` JWT standard claim (key id)	optional
`iss`	string	`iss` JWT standard claim (issuer)	optional
`sub`	string	`sub` JWT standard claim (subject)	optional
`aud`	string	`aud` JWT standard claim (audience)	optional
`jti`	string	`jti` JWT standard claim (JWT id)	optional
`ttl`	string	JWT token TTL	`1h`
Description of fields of `creds_json` (FIXED)			
`type`	string	Token source type. Set `FIXED`	
`token`	string	Token value	
`token-type`	string	Token type value. It will become `subject_token_type/actor_token_type` parameter in token exchange request.	

Example

An example for JWT token exchange

```
{
  "subject-credentials": {
    "type": "JWT",
    "alg": "RS256",
    "private-key": "-----BEGIN RSA PRIVATE KEY-----\n...-----END RSA PRIVATE KEY-----\n",
    "kid": "my_key_id",
    "sub": "account_id"
  }
}
```

Peculiarities of YDB Python SDK v2 (deprecated version)

Warning

The behavior of the YDB Python SDK v2 (deprecated version) differs from the above-described version.

- The algorithm of the `construct_credentials_from_environ()` function from the YDB Python SDK v2:
  - If the value of the `USE_METADATA_CREDENTIALS` environment variable is set to 1, the **Metadata** authentication mode is used.
  - Otherwise, if the value of the `YDB_TOKEN` environment variable is set, the **Access Token** authentication mode is used, where this variable value is passed.
  - Otherwise, if the value of the `SA_KEY_FILE` environment variable is set, the **System Account Key** authentication mode is used and the key is taken from the file whose name is specified in this variable.
  - Or else, no authentication information is added to requests.
- If no object responsible for generating tokens is passed when initializing the driver, the general procedure for reading environment variables applies.

Parameterized queries

YDB supports and recommends the use of so-called parameterized queries. In such queries, data is transmitted separately from the query body itself, and special parameters in the SQL query are used to indicate where the data goes. Parameterized query plans are cached on the server (by default, up to 1000 entries), which lets you reuse plans for similar queries that differ only in parameter values.

In many YDB SDKs, parameterized query caching is enabled by default. You can disable it if needed by setting the `KeepInCache` parameter to `false`.

Request with data in the request body:

```
SELECT sa.title AS season_title, sr.title AS series_title
FROM seasons AS sa INNER JOIN series AS sr ON sa.series_id = sr.series_id
WHERE sa.series_id = 15 AND sa.season_id = 3
```

The corresponding parameterized query:

```
DECLARE $seriesId AS Uint64;
DECLARE $seasonId AS Uint64;

SELECT sa.title AS season_title, sr.title AS series_title
FROM seasons AS sa INNER JOIN series AS sr ON sa.series_id = sr.series_id
WHERE sa.series_id = $seriesId AND sa.season_id = $seasonId
```

Parameterized queries are written in the form of a template in which certain types of names are replaced with specific parameters each time the query is executed. Tokens starting with the sign `$` such as `$seriesId` and `$seasonId` in the query above are used to denote parameters.

Parameterized queries provide the following advantages:

- For repeated requests, the database server can cache the query plan for parameterized queries. This radically reduces CPU consumption and increases system throughput.
- The use of parameterized queries protects against vulnerabilities such as SQL Injection.
- Less code — only the query arguments change, not the query itself. You do not need to concatenate the query string manually.

Data formats

YDB supports several data representation formats and schema return modes for queries executed through QueryService. The format and schema return mode are set when the query runs and apply to every statement that returns data (for example, a SELECT statement or the `RETURNING` clause). How you configure these settings may differ across SDKs.

Data representation formats

The following sections describe the available data representation formats:

- Protobuf (Value) — the default format; rows are returned one by one with automatic conversion to native types in your programming language.
- Apache Arrow — a columnar format for analytics workloads and high-throughput transfer of large result sets.

Schema return modes

When a query runs as a stream, results arrive in parts. The schema return mode controls which parts of the stream include schema information.

- **Always (default)** — the data schema is included in every part of the result stream. Convenient when each part is processed independently.
- **First only** — the data schema is included only in the first part of the stream for each result set; later parts omit it. Reduces metadata volume when you stream large results.

The exact schema payload depends on the data format; each format's section describes what is returned.

Protobuf (Value) format

This is the default format. Data is returned row by row as Protobuf: each row is a serialized set of named values with their YQL types. The SDK converts values to native types for your language and exposes a type-safe API.

Use this format when you need:

- Transactional (OLTP) workloads with point reads of individual rows.
- Applications that process small fragments of a table at full row width.
- Native integration with your language's types.

YQL type mapping

Mapping from YQL types to native language types is implemented in the SDK and depends on the SDK you use. See your SDK's documentation for the exact mapping.

Returned schema

The schema is a list of columns with their YQL types. That is enough for the SDK to interpret values: given the column type, each value is converted to a native type.

SDK examples

Python

This format is the default when you run queries through QueryService. The example below shows how to set the result format explicitly.

```
pool = ydb.QuerySessionPool(driver)

query = """
    SELECT * FROM example ORDER BY Key LIMIT 100;
"""

result = pool.execute_with_retries(
    query,
    result_set_format=ydb.QueryResultSetFormat.VALUE,
    schema_inclusion_mode=ydb.QuerySchemaInclusionMode.FIRST_ONLY,
)

for result_set in result:
    print(f"Record batch with {len(result_set.rows)} rows and {len(result_set.columns)} columns")
```

Java

This format is the default when you run queries through QueryService.

Apache Arrow format

Results are returned in the columnar Apache Arrow format (IPC standard, version 5.0) without conversion inside the SDK, which makes large result sets efficient to process.

Prefer this format for:

- Analytical (OLAP) workloads with columnar processing — aggregations, filters, scans over multiple columns on large samples.
- Systems that integrate natively with Apache Arrow.
- Scenarios where throughput for large data transfers matters most.

YQL type mapping

YQL data types are mapped to Apache Arrow types as follows.

Numeric types

YQL type	Arrow type	Notes
`Bool`	`uint8`	`true` / `false` encoded as `1` / `0`
`Int8`	`int8`	
`Int16`	`int16`	
`Int32`	`int32`	
`Int64`	`int64`	
`Uint8`	`uint8`	
`Uint16`	`uint16`	
`Uint32`	`uint32`	
`Uint64`	`uint64`	
`Float`	`float`	
`Double`	`double`	
`Decimal(p, s)`	`fixed_size_binary(16)`	120 bits used; ±inf and NaN markers supported
`DyNumber`	`string`	String representation of the number

String types

YQL type	Arrow type	Notes
`String`	`binary`	
`Utf8`	`string`	
`Json`	`string`	
`JsonDocument`	`string`	String form of binary JSON
`Yson`	`binary`	
`Uuid`	`fixed_size_binary(16)`	16 bytes in mixed-endian order

Date and time types

YQL type	Arrow type	Notes
`Date`	`uint16`	Day precision
`Date32`	`int32`	Day precision
`Datetime`	`uint32`	Second precision
`Datetime64`	`int64`	Second precision
`Timestamp`	`uint64`	Microsecond precision
`Timestamp64`	`int64`	Microsecond precision
`Interval`	`int64`	Microseconds
`Interval64`	`int64`	Microseconds
`TzDate`	`struct<datetime: uint16, timezone: string>`	Time zone name as a string
`TzDate32`	`struct<datetime: int32, timezone: string>`	Time zone name as a string
`TzDatetime`	`struct<datetime: uint32, timezone: string>`	Time zone name as a string
`TzDatetime64`	`struct<datetime: int64, timezone: string>`	Time zone name as a string
`TzTimestamp`	`struct<datetime: uint64, timezone: string>`	Time zone name as a string

`TzTimestamp64`	`struct<datetime: int64, timezone: string>`	Time zone name as a string

> **Note**
>
> In Arrow, basic date/time types are represented as unsigned integers, while extended date/time types types use signed integers.

Container types

YQL type	Arrow type	Notes
`List<T>`	`list<item: T>`	
`Tuple<T1, T2, ...>`	`struct<field0: T1, field1: T2, ...>`	
`Struct<name: T, ...>`	`struct<name: T, ...>`	
`Dict<K, V>`	`list<struct<key: K, payload: V>>`	
`Set<T>`	`list<struct<key: T, payload: struct<>>>`	Same as `Dict<T, Void>`
`Variant<T1, ..., Tn>`	`dense_union<field0: T1, ...>`	For n <= 128
`Variant<T1, ..., Tn>`	`dense_union<dense_union<field0: T1, ...>, ...>`	For 128 < n <= 16384
`Variant<name1: T1, ..., nameN: Tn>`	`dense_union<name1: T1, ...>`	For n <= 128
`Variant<name1: T1, ..., nameN: Tn>`	`dense_union<dense_union<name1: T1, ...>, ...>`	For 128 < n <= 16384

> **Warning**
>
> `Variant` over tuple or struct cannot be represented in Apache Arrow if the number of child types exceeds 16384 (128 * 128).

Optional and special types

YQL type	Arrow type	Notes
`Null`	`null`	Singular type
`Void`	`struct<>`	Singular type
`EmptyList`	`struct<>`	Singular type
`EmptyDict`	`struct<>`	Singular type
`Tagged<T>`	`T`	Tag stripped
`Optional<T>`	`struct<opt: T>`	When `T` is `Variant`, `Optional`, `Pg`, or singular
`Optional<T>`	`T`	For all other `T`

Types in the `pg` family

All `pg` types are represented as Arrow `string` values containing the textual form.

Data compression

You can enable compression for Arrow payloads. Supported codecs:

Codec	Description
None (default)	
`ZSTD`	Zstandard. Compression level is configurable
`LZ4_FRAME`	LZ4. Compression level is not configurable

Returned schema

The schema has two parts:

- **Column list with YQL types** — describes the logical types in YQL terms so your application can interpret semantics regardless of Arrow representation details.
- **Serialized Arrow RecordBatch schema** — describes the binary layout in Apache Arrow terms. Required to deserialize RecordBatch on the client.

Both are needed because YQL and Arrow types do not always map one-to-one.

Apache Arrow examples in the SDK

Python

```python
import pyarrow

pool = ydb.QuerySessionPool(driver)

query = """
    SELECT * FROM example ORDER BY Key LIMIT 100;
"""

format_settings = ydb.ArrowFormatSettings(
    compression_codec=ydb.ArrowCompressionCodec(ydb.ArrowCompressionCodecType.ZSTD, 10)
)

result = pool.execute_with_retries(
    query,
    result_set_format=ydb.QueryResultSetFormat.ARROW,
    schema_inclusion_mode=ydb.QuerySchemaInclusionMode.FIRST_ONLY,
    arrow_format_settings=format_settings,
)

for result_set in result:
    schema = pyarrow.ipc.read_schema(pyarrow.py_buffer(result_set.arrow_format_meta.schema))
    batch = pyarrow.ipc.read_record_batch(pyarrow.py_buffer(result_set.data), schema)
    print(f"Record batch with {batch.num_rows} rows and {batch.num_columns} columns")
```

Java

```java
String query = "SELECT * FROM example ORDER BY Key LIMIT 100;";

ExecuteQuerySettings settings = ExecuteQuerySettings.newBuilder()
        .useApacheArrowFormat(ApacheArrowFormat.zstd())
        .build();

try (RootAllocator allocator = new RootAllocator()) {
    retryCtx.supplyResult(session -> session
            .createQuery(query, TxMode.SERIALIZABLE_RW, Params.empty(), settings)
            .execute(new ApacheArrowCompressedPartsHandler(allocator) {
                @Override
                public void onNextPart(QueryResultPart part) {
                    ResultSetReader rs = part.getResultSetReader();
                    while (rs.next()) {
                        String key = rs.getColumn("Key").getText();
                        System.out.println("Read row with key " + key);
                    }
                    System.out.printf("Record batch with %d rows and %d columns%n",
                            rs.getRowCount(), rs.getColumnCount());
                }
            })
    ).join().getStatus().expectSuccess("execute query problem");
}
```

Working with topics

This article provides examples of how to use the YDB SDK to work with topics.

Before performing the examples, create a topic and add a consumer.

Topic usage examples

C++

Reader example on GitHub

Go

Examples on GitHub

Java

Examples on GitHub

Python

Examples on GitHub

C#

Examples on GitHub

JavaScript

Examples on GitHub

Rust

Examples on GitHub (`topic-writer`, `topic-reader-retry`, `topic-read-in-transaction-example`).

Initializing a connection

Go

Use a YDB driver instance created with `ydb.Open`. The topic client is available via `db.Topic()`.

```
package main

import (
  "context"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/topic/topicoptions"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)

  // db.Topic() — client for topics
  writer, err := db.Topic().StartWriter("topic-path")
  if err != nil {
    panic(err)
  }

  reader, err := db.Topic().StartReader("consumer-name",
    topicoptions.ReadTopic("topic-path"),
  )
  if err != nil {
    panic(err)
  }
  _ = writer
  _ = reader
}
```

C++

To interact with YDB Topics, create an instance of the YDB driver and topic client.

The YDB driver lets the app and YDB interact at the transport layer. The driver must exist during the YDB access lifecycle and be initialized before creating a client.

Topic client (source code) requires the YDB driver for work. It handles topics and manages read and write sessions.

App code snippet for driver initialization:

```
auto driverConfig = NYdb::TDriverConfig()
    .SetEndpoint(opts.Endpoint)
    .SetDatabase(opts.Database)
    .SetAuthToken(std::getenv("YDB_TOKEN"));

NYdb::TDriver driver(driverConfig);
```

This example uses authentication token from the `YDB_TOKEN` environment variable. For details see Connecting to a database and Authentication pages.

App code snippet for creating a client:

```
NYdb::NTopic::TTopicClient topicClient(driver);
```

Java

To interact with YDB Topics, create an instance of the YDB transport and topic client.

The YDB transport lets the app and YDB interact at the transport layer. The transport must exist during the YDB access lifecycle and be initialized before creating a client.

App code snippet for transport initialization:

```
try (GrpcTransport transport = GrpcTransport.forConnectionString(connString)
        .withAuthProvider(CloudAuthHelper.getAuthProviderFromEnviron())
        .build()) {
    // Use YDB transport
}
```

In this example `CloudAuthHelper.getAuthProviderFromEnviron()` helper method is used which retrieves auth token from environment variables.
For example, `YDB_ACCESS_TOKEN_CREDENTIALS`.
For details see Connecting to a database and Authentication pages.

Topic client (source code) uses YDB transport and handles all topics topic operations, manages read and write sessions.

App code snippet for creating a client:

```
try (TopicClient topicClient = TopicClient.newClient(transport)
              .setCompressionExecutor(compressionExecutor)
              .build()) {
  // Use topic client
}
```

Both provided examples use (try-with-resources) block.
It allows to automatically close client and transport on leaving this block, considering both classes extends `AutoCloseable`.

C#

To interact with YDB Topics, create an instance of the YDB driver and topic client.

The YDB transport allows the app and YDB to interact at the transport layer. The transport must exist during the YDB access lifecycle and be initialized before creating a client.

App code snippet for transport initialization:

```
var config = new DriverConfig(
    endpoint: "grpc://localhost:2136",
    database: "/local"
);

await using var driver = await Driver.CreateInitialized(
    config: config,
    loggerFactory: loggerFactory
);
```

This example uses anonymous authentication. For details, see Connecting to a database and Authentication.

App code snippet for creating various clients:

```
var topicClient = new TopicClient(driver);

await using var writer = new WriterBuilder<string>(driver, topicName)
{
    ProducerId = "ProducerId_Example"
}.Build();

await using var reader = new ReaderBuilder<string>(driver)
{
    ConsumerName = "Consumer_Example",
    SubscribeSettings = { new SubscribeSettings(topicName) }
}.Build();
```

Python

To work with topics, create a YDB driver instance. The topic client is available via the `topic_client` attribute and is used for management operations on topics and for creating writers and readers.

Native SDK

```
import os
import ydb

driver_config = ydb.DriverConfig(
    endpoint=os.environ["YDB_ENDPOINT"],
    database=os.environ["YDB_DATABASE"],
)
driver = ydb.Driver(driver_config)
driver.wait(timeout=5)
# driver.topic_client — client for working with topics
writer = driver.topic_client.writer(topic_path)
reader = driver.topic_client.reader(topic=topic_path, consumer=consumer_name)
```

Native SDK (Asyncio)

```
import os
import ydb

driver_config = ydb.DriverConfig(
    endpoint=os.environ["YDB_ENDPOINT"],
    database=os.environ["YDB_DATABASE"],
)
async with ydb.aio.Driver(driver_config) as driver:
    await driver.wait(timeout=5)
    # driver.topic_client — client for working with topics
    writer = driver.topic_client.writer(topic_path)
    reader = driver.topic_client.reader(topic=topic_path, consumer=consumer_name)
```

For more on connecting to the database and authentication.

JavaScript

```
const t = topic(driver);

await using reader = t.createReader({
  topic: "/Root/demo-topic",
  consumer: "demo-consumer",
});

await using writer = t.createWriter({
  topic: "/Root/demo-topic",
  producer: "demo-producer",
});
```

Rust

```
use ydb::{ClientBuilder, YdbResult};

#[tokio::main]
async fn main() -> YdbResult<()> {
    let client = ClientBuilder::new_from_connection_string("grpc://localhost:2136/local")?.client()?;
    client.wait().await?;
    let mut topic_client = client.topic_client();
    // topic_client.create_reader(...), create_writer_with_params(...), ...
    Ok(())
}
```

Managing topics

Creating a topic

C++

For a full list of supported parameters, see the source code.

Example of creating a topic with three partitions and ZSTD codec support:

```
auto settings = NYdb::NTopic::TCreateTopicSettings()
    .PartitioningSettings(3, 3)
    .AppendSupportedCodecs(NYdb::NTopic::ECodec::ZSTD);

auto status = topicClient
    .CreateTopic("my-topic", settings)  // returns TFuture<TStatus>
    .GetValueSync();
```

Go

For a full list of supported parameters, see the SDK documentation.

Example of creating a topic with a list of supported codecs and a minimum number of partitions:

```
err := db.Topic().Create(ctx, "topic-path",
  // optional
  topicoptions.CreateWithSupportedCodecs(topictypes.CodecRaw, topictypes.CodecGzip),

  // optional
  topicoptions.CreateWithMinActivePartitions(3),
)
```

Python

Example of creating a topic with a list of supported codecs and a minimum number of partitions:

Native SDK

```
driver.topic_client.create_topic(topic_path,
    supported_codecs=[ydb.TopicCodec.RAW, ydb.TopicCodec.GZIP], # optional
    min_active_partitions=3,                                    # optional
)
```

Native SDK (Asyncio)

```
await driver.topic_client.create_topic(topic_path,
    supported_codecs=[ydb.TopicCodec.RAW, ydb.TopicCodec.GZIP],  # optional
    min_active_partitions=3,                                     # optional
)
```

Java

For a full list of supported parameters, see the source code.

```
topicClient.createTopic(topicPath, CreateTopicSettings.newBuilder()
                // Optional
                .setSupportedCodecs(SupportedCodecs.newBuilder()
                        .addCodec(Codec.RAW)
                        .addCodec(Codec.GZIP)
                        .build())
                // Optional
                .setPartitioningSettings(PartitioningSettings.newBuilder()
                        .setMinActivePartitions(3)
                        .build())
                .build());
```

C#

Example of creating a topic with a list of supported codecs and a minimum number of partitions:

```
await topicClient.CreateTopic(new CreateTopicSettings
{
    Path = topicName,
    Consumers = { new Consumer("Consumer_Example") },
    SupportedCodecs = { Codec.Raw, Codec.Gzip },
    PartitioningSettings = new PartitioningSettings
    {
        MinActivePartitions = 3
    }
});
```

JavaScript

```
const topicService = driver.createClient(TopicServiceDefinition);
await topicService.createTopic(
  create(CreateTopicRequestSchema, {
    path: "/path-to-my-topic",
    partitioningSettings: {
      minActivePartitions: 1n,
      maxActivePartitions: 100n,
    },
    consumers: [{ name: "my-consumer" }],
  }),
);
```

Rust

```
use ydb::{Codec, CreateTopicOptionsBuilder, YdbResult};

topic_client
    .create_topic(
        "/local/my-topic".into(),
        CreateTopicOptionsBuilder::default()
            .min_active_partitions(3)
            .supported_codecs(vec![Codec::Raw, Codec::Zstd])
            .build()?,
    )
    .await?;
```

Updating a topic

When you update a topic, you must specify the topic path and the parameters to be changed.

C++

For a full list of supported parameters, see the source code.

Example of adding an important consumer and setting two days retention time for the topic:

```
auto alterSettings = NYdb::NTopic::TAlterTopicSettings()
    .BeginAddConsumer("my-consumer")
        .Important(true)
    .EndAddConsumer()
    .SetRetentionPeriod(TDuration::Days(2));

auto status = topicClient
    .AlterTopic("my-topic", alterSettings)  // returns TFuture<TStatus>
    .GetValueSync();
```

Go

For a full list of supported parameters, see the SDK documentation.

Example of adding a consumer to a topic:

```
err := db.Topic().Alter(ctx, "topic-path",
  topicoptions.AlterWithAddConsumers(topictypes.Consumer{
    Name:            "new-consumer",
    SupportedCodecs: []topictypes.Codec{topictypes.CodecRaw, topictypes.CodecGzip}, // optional
  }),
)
```

Python

Example of updating a topic's list of supported codecs and minimum number of partitions:

Native SDK

```
driver.topic_client.alter_topic(topic_path,
    set_supported_codecs=[ydb.TopicCodec.RAW, ydb.TopicCodec.GZIP], # optional
    set_min_active_partitions=3,                                    # optional
)
```

Native SDK (Asyncio)

```
await driver.topic_client.alter_topic(topic_path,
    set_supported_codecs=[ydb.TopicCodec.RAW, ydb.TopicCodec.GZIP],  # optional
    set_min_active_partitions=3,                                     # optional
)
```

Java

For a full list of supported parameters, see the source code.

```
topicClient.alterTopic(topicPath, AlterTopicSettings.newBuilder()
                .addAddConsumer(Consumer.newBuilder()
                        .setName("new-consumer")
                        .setSupportedCodecs(SupportedCodecs.newBuilder()
                                .addCodec(Codec.RAW)
                                .addCodec(Codec.GZIP)
                                .build())
                        .build())
                .build());
```

JavaScript

```
const topicService = driver.createClient(TopicServiceDefinition);
await topicService.alterTopic(
  create(AlterTopicRequestSchema, {
    path: "/path-to-my-topic",
    addConsumers: [{ name: "my-consumer-2" }],
  }),
);
```

Rust

```
use ydb::{AlterTopicOptionsBuilder, YdbResult};

topic_client
    .alter_topic(
        "/local/my-topic".into(),
        AlterTopicOptionsBuilder::default()
            .set_min_active_partitions(Some(5))
            .build()?,
    )
    .await?;
```

Getting topic information

C++

Use `DescribeTopic` method to get information about topic.

For a full list of description fields, see the source code.

Example of using topic description:

```
auto result = topicClient.DescribeTopic("my-topic").GetValueSync();
if (result.IsSuccess()) {
    const auto& description = result.GetTopicDescription();
    std::cout << "Topic description: " << GetProto(description) << std::endl;
}
```

There is another method `DescribeConsumer` to get informtaion about consumer.

Go

```
  descResult, err := db.Topic().Describe(ctx, "topic-path")
if err != nil {
  log.Fatalf("failed drop topic: %v", err)
  return
}
fmt.Printf("describe: %#v\n", descResult)
```

Python

Native SDK

```
info = driver.topic_client.describe_topic(topic_path)
print(info)
```

Native SDK (Asyncio)

```
info = await driver.topic_client.describe_topic(topic_path)
print(info)
```

Java

Use `describeTopic` method to get information about topic.

For a full list of description fields, see the source code.

```
Result<TopicDescription> topicDescriptionResult = topicClient.describeTopic(topicPath)
        .join();
TopicDescription description = topicDescriptionResult.getValue();
```

JavaScript

```
const topicService = driver.createClient(TopicServiceDefinition);
await topicService.describeTopic(
  create(DescribeTopicRequestSchema, {
    path: "/path-to-my-topic",
  }),
);
```

Rust

```
use ydb::{DescribeTopicOptionsBuilder, YdbResult};

let description = topic_client
    .describe_topic(
        "/local/my-topic".into(),
        DescribeTopicOptionsBuilder::default().include_stats(true).build()?,
    )
    .await?;
```

Deleting a topic

To delete a topic, just specify the path to it.

C++

```
auto status = topicClient.DropTopic("my-topic").GetValueSync();
```

Go

```
  err := db.Topic().Drop(ctx, "topic-path")
```

Python

Native SDK

```
driver.topic_client.drop_topic(topic_path)
```

Native SDK (Asyncio)

```
await driver.topic_client.drop_topic(topic_path)
```

Java

```
topicClient.dropTopic(topicPath);
```

C#

```
await topicClient.DropTopic(topicName);
```

JavaScript

```
const topicService = driver.createClient(TopicServiceDefinition);
await topicService.dropTopic(
  create(DropTopicRequestSchema, {
    path: "/path-to-my-topic",
  }),
);
```

Rust

```
topic_client.drop_topic("/local/my-topic".into()).await?;
```

Message writes

Connecting to a topic for message writes

Only connections with matching producer and message group identifiers are currently supported (`producer_id` shoud be equal to `message_group_id`). This restriction will be removed in the future.

C++

The write session object with `IWriteSession` interface is used to connect to a topic for writing.

For a full list of write session settings, see the source code.

Example of creating a write session:

```
std::string producerAndGroupID = "group-id";
auto settings = NYdb::NTopic::TWriteSessionSettings()
    .Path("my-topic")
    .ProducerId(producerAndGroupID)
    .MessageGroupId(producerAndGroupID);

auto session = topicClient.CreateWriteSession(settings);
```

Go

```
producerAndGroupID := "group-id"
writer, err := db.Topic().StartWriter(producerAndGroupID, "topicName",
  topicoptions.WithMessageGroupID(producerAndGroupID),
)
if err != nil {
    return err
}
```

Python

Native SDK

```
writer = driver.topic_client.writer(topic_path)
```

Native SDK (Asyncio)

```
writer = driver.topic_client.writer(topic_path)
```

Java

Synchronous API

Writer settings initialization:

```
String producerAndGroupID = "group-id";
WriterSettings settings = WriterSettings.newBuilder()
      .setTopicPath(topicPath)
      .setProducerId(producerAndGroupID)
      .setMessageGroupId(producerAndGroupID)
      .build();
```

Sync writer creation:

```
SyncWriter writer = topicClient.createSyncWriter(settings);
```

After the writer is created, initialize it. There are two methods:

- `init()`: non-blocking; starts initialization in the background and does not wait for completion.

  ```
  writer.init();
  ```

- `initAndWait()`: blocking; starts initialization and waits for completion. If initialization fails, an exception is thrown.

  ```
  try {
      writer.initAndWait();
      logger.info("Init finished successfully");
  } catch (Exception exception) {
      logger.error("Exception while initializing writer: ", exception);
      return;
  }
  ```

Asynchronous API

Writer settings initialization:

```
String producerAndGroupID = "group-id";
WriterSettings settings = WriterSettings.newBuilder()
      .setTopicPath(topicPath)
      .setProducerId(producerAndGroupID)
      .setMessageGroupId(producerAndGroupID)
      .build();
```

Async writer creation and initialization:

```
AsyncWriter writer = topicClient.createAsyncWriter(settings);

// Init in background
writer.init()
        .thenRun(() -> logger.info("Init finished successfully"))
        .exceptionally(ex -> {
            logger.error("Init failed with ex: ", ex);
            return null;
        });
```

C#

```
await using var writer = new WriterBuilder<string>(driver, topicName)
{
    ProducerId = "ProducerId_Example"
}.Build();
```

JavaScript

```
await using writer = createTopicWriter(driver, {
  topic: topicName,
  producer: producerName,
});
```

Rust

```rust
use ydb::{TopicWriter, TopicWriterOptionsBuilder, YdbResult};

let writer: TopicWriter = topic_client
    .create_writer_with_params(
        TopicWriterOptionsBuilder::default()
            .topic_path("/local/my-topic".into())
            .producer_id("group-id".into())
            .message_group_id("group-id".into())
            .build()?,
    )
    .await?;
```

Writing messages

C++

`IWriteSession` interface allows asynchronous write.

The user processes three kinds of events in a loop: `TReadyToAcceptEvent`, `TAcksEvent`, and `TSessionClosedEvent`.

For each kind of event user can set a handler in write session settings before session creation. Also, a common handler can be set.

If handler is not set for a particular event, it will be delivered to SDK client via `GetEvent` / `GetEvents` methods. `WaitEvent` method allows user to await for a next event in non-blocking way with `TFuture<void>()` interface.

To write a message, user uses a move-only `TContinuationToken` object, which has been created by the SDK and has been delivered to the user with a `TReadyToAcceptEvent` event. During write user can set an arbitrary sequential number and a message creation timestamp. By default they are generated by the SDK.

`Write` is asynchronous. Data from messages is processed and stored in the internal buffer. Settings `MaxMemoryUsage`, `MaxInflightCount`, `BatchFlushInterval`, and `BatchFlushSizeBytes` control sending in the background. Write session reconnects to the YDB if the connection fails and resends the message if possible, with regard to `RetryPolicy` setting. If an error that cannot be repeated is received, write session stops and sends `TSessionClosedEvent` to the client.

Example of writing using event loop without any handlers set up:

```
// Event loop
while (true) {
    // Get event
    // May block for a while if write session is busy
    std::optional<NYdb::NTopic::TWriteSessionEvent::TEvent> event = session->GetEvent(/*block=*/true);

    if (auto* readyEvent = std::get_if<NYdb::NTopic::TWriteSessionEvent::TReadyToAcceptEvent>(&*event)) {
        session->Write(std::move(event.ContinuationToken), "This is yet another message.");

    } else if (auto* ackEvent = std::get_if<NYdb::NTopic::TWriteSessionEvent::TAcksEvent>(&*event)) {
        std::cout << ackEvent->DebugString() << std::endl;

    } else if (auto* closeSessionEvent = std::get_if<NYdb::NTopic::TSessionClosedEvent>(&*event)) {
        break;
    }
}
```

Go

To send a message, just save Reader in the Data field, from which the data can be read. You can expect the data of each message to be read once (or until the first error). By the time you return the data from Write, it will already have been read and stored in the internal buffer.

By default, SeqNo and the message creation date are set automatically.

By default, Write is performed asynchronously: data from messages is processed and stored in the internal buffer, sending is done in the background. Writer reconnects to the YDB if the connection fails and resends the message if possible. If an error that cannot be repeated is received , Writer stops and subsequent Write calls will end with an error.

```
err := writer.Write(ctx,
  topicwriter.Message{Data: strings.NewReader("1")},
  topicwriter.Message{Data: bytes.NewReader([]byte{1,2,3})},
  topicwriter.Message{Data: strings.NewReader("3")},
)
if err != nil {
  return err
}
```

Python

To deliver messages, you can either simply transmit message content (bytes, str) or set certain properties manually. You can send objects one-by-one or as a list. The `write` method is asynchronous. The method returns immediately once messages are put to the client's internal buffer; this is usually a fast process. If the internal buffer is filled up, you might need to wait until part of the data is sent to the server.

Native SDK

```
# Simple delivery of messages, without explicit metadata.
# Easy to get started, easy to use if everything you need is the message content.
writer = driver.topic_client.writer(topic_path)
writer.write("mess")  # Rows will be transmitted in UTF-8; this is the easiest way to send
                      # text messages.
writer.write(bytes([1, 2, 3]))  # These bytes will be transmitted as they are, this is the easiest way to sen
d
                                # binary data.
writer.write(["mess-1", "mess-2"])  # This line sends multiple messages per call
                                    # to decrease overheads on internal SDK processes.
                                    # This makes sense when the message stream is high.

# This is the full form; it is used when except the message content you need to manually specify its properti
es.
writer = driver.topic_client.writer(topic="topic-path", auto_seqno=False, auto_created_at=False)

writer.write(ydb.TopicWriterMessage("asd", seqno=123, created_at=datetime.datetime.now()))
writer.write(ydb.TopicWriterMessage(bytes([1, 2, 3]), seqno=124, created_at=datetime.datetime.now()))

# In the full form, you can also send multiple messages per function call.
# This approach is useful when the message stream is high, and you want to
# reduce overheads on SDK internal calls.
writer.write([
  ydb.TopicWriterMessage("asd", seqno=123, created_at=datetime.datetime.now()),
  ydb.TopicWriterMessage(bytes([1, 2, 3]), seqno=124, created_at=datetime.datetime.now(),
  ])
```

Native SDK (Asyncio)

```
writer = driver.topic_client.writer(topic_path)
await writer.write("mess")
await writer.write(bytes([1, 2, 3]))
await writer.write(["mess-1", "mess-2"])
```

Java

Synchronous API

The `send` method blocks until a message is placed in the writer's send queue.
Putting a message in this queue means the writer will do its best to deliver it.
For example, if the write session is dropped, the writer reconnects and tries to resend the message on a new session.
However, enqueueing does not guarantee the message will eventually be written.
Errors can shut down the writer before queued messages are sent.
If you need a per-message guarantee that data was written, use the async writer and inspect the status returned by `send`.

```
writer.send(Message.of("11".getBytes()));

long timeoutSeconds = 5; // How long should we wait for a message to be put into sending buffer
try {
    writer.send(
            Message.newBuilder()
                    .setData("22".getBytes())
                    .setCreateTimestamp(Instant.now().minusSeconds(5))
                    .build(),
            timeoutSeconds,
            TimeUnit.SECONDS
    );
} catch (TimeoutException exception) {
    logger.error("Send queue is full. Couldn't put message into sending queue within {} seconds", timeoutSeco
nds);
} catch (InterruptedException | ExecutionException exception) {
    logger.error("Couldn't put the message into sending queue due to exception: ", exception);
}
```

Asynchronous API

The `send` method is non-blocking for the async client. It enqueues a message for sending.
It returns `CompletableFuture<WriteAck>` so you can verify the message was actually written.
If the queue overflows, `QueueOverflowException` is thrown.
That signals the producer should slow down: skip messages or retry with exponential backoff.
You can also increase the client buffer size (`setMaxSendBufferMemorySize`) to hold more messages before overflow.

```
try {
    // Non-blocking. Throws QueueOverflowException if send queue is full
    writer.send(Message.of("33".getBytes()));
} catch (QueueOverflowException exception) {
    // Send queue is full. Need to retry with backoff or skip
}
```

C#

Asynchronous writing of a message to a topic.

```
var asyncWriteTask = writer.WriteAsync("Hello, Example YDB Topics!"); // Task<WriteResult>
```

JavaScript

```
// Write a message to the internal buffer.
writer.write(Buffer.from("Hello, world!", "utf-8"));

// To send immediately, call flush.
await writer.flush();

// Or close the writer.
await writer.close();
```

Rust

```
use ydb::{TopicWriterMessageBuilder, YdbResult};

writer
    .write(
        TopicWriterMessageBuilder::default()
            .data(b"payload".to_vec())
            .build()?,
    )
    .await?;
writer.stop().await?;
```

Message writes with storage confirmation on the server

C++

`IWriteSession` interface allows getting server acknowledgments for writes.

Status of server-side message write is represented with `TAcksEvent`. One event can contain the statuses of several previously sent messages.Status is one of the following: message write is confirmed (`EES_WRITTEN`), message is discarded as a duplicate of a previously written message (`EES_ALREADY_WRITTEN`) or message is discarded because of failure (`EES_DISCARDED`).

Example of setting TAcksEvent handler for a write session:

```
auto settings = NYdb::NTopic::TWriteSessionSettings()
  // other settings are set here
  .EventHandlers(
    NYdb::NTopic::TWriteSessionSettings::TEventHandlers()
      .AcksHandler(
        [&](NYdb::NTopic::TWriteSessionEvent::TAcksEvent& event) {
          for (const auto& ack : event.Acks) {
            if (ack.State == NYdb::NTopic::TWriteSessionEvent::TWriteAck::EEventState::EES_WRITTEN) {
              ackedSeqNo.insert(ack.SeqNo);
              std::cout << "Acknowledged message with seqNo " << ack.SeqNo << std::endl;
            }
          }
        }
      )
  );

auto session = topicClient.CreateWriteSession(settings);
```

In this write session user does not receive `TAcksEvent` events in the `GetEvent` / `GetEvents` loop. Instead, SDK will call given handler on every acknowledgment coming from server. In the same way user can set up handlers for other types of events.

Go

When connected, you can specify the synchronous message write option: topicoptions.WithSyncWrite(true). Then Write will only return after receiving a confirmation from the server that all messages passed in the call have been saved. If necessary, the SDK will reconnect and retry sending messages as usual. In this mode, the context only controls the response time from the SDK, meaning the SDK will continue trying to send messages even after the context is canceled.

```
producerAndGroupID := "group-id"
writer, _ := db.Topic().StartWriter(producerAndGroupID, "topicName",
  topicoptions.WithMessageGroupID(producerAndGroupID),
  topicoptions.WithSyncWrite(true),
)

err = writer.Write(ctx,
  topicwriter.Message{Data: strings.NewReader("1")},
  topicwriter.Message{Data: bytes.NewReader([]byte{1,2,3})},
  topicwriter.Message{Data: strings.NewReader("3")},
)
if err != nil {
  return err
}
```

Python

There are two ways to get a message write acknowledgement from the server:

- `flush()` - waits until all the messages previously written to the internal buffer are acknowledged.
- `write_with_ack(...)` - sends a message and waits for the acknowledgement of its delivery from the server. This method is slow when you are sending multiple messages in a row.

```
# Put multiple messages to the internal buffer and then wait
# until all of them are delivered to the server.
for mess in messages:
    writer.write(mess)

writer.flush()

# You can send multiple messages and wait for an acknowledgment for the entire group.
writer.write_with_ack(["mess-1", "mess-2"])

# Waiting on sending each message: this method will return the result only after an
# acknowledgment from the server.
# This is the slowest message delivery option; use it when this mode is
# absolutely needed.
writer.write_with_ack("message")
```

Java

The `send` method returns `CompletableFuture<WriteAck>`. Successful completion means the server acknowledged the write. The `WriteAck` structure contains seqNo, offset, and write status:

```
writer.send(Message.of(message))
      .whenComplete((result, ex) -> {
          if (ex != null) {
              logger.error("Exception on writing message message: ", ex);
          } else {
              switch (result.getState()) {
                  case WRITTEN:
                      WriteAck.Details details = result.getDetails();
                      StringBuilder str = new StringBuilder("Message was written successfully");
                      if (details != null) {
                          str.append(", offset: ").append(details.getOffset());
                      }
                      logger.debug(str.toString());
                      break;
                  case ALREADY_WRITTEN:
                      logger.warn("Message has already been written");
                      break;
                  default:
                      break;
              }
          }
      });
```

C#

Asynchronous writing of a message to a topic. If the internal buffer overflows, it waits for the buffer to be released before resending.

```
await writer.WriteAsync("Hello, Example YDB Topics!");
```

If the server is unavailable, messages may accumulate while waiting to be sent. In this case, you can pass a cancellation token (`CancellationToken`) to control waiting. However, if the user cancels the recorded message, it will still be canceled.

```
var writeCts = new CancellationTokenSource();
writeCts.CancelAfter(TimeSpan.FromSeconds(3));

await writer.WriteAsync("Hello, Example YDB Topics!", writeCts.Token);
```

JavaScript

All messages are written to an internal buffer. There are three mechanisms they reach the server: two automatic and one manual. The manual path is calling `writer.flush`, which returns the last seqNo persisted on the server. Automatic flushes happen when:

- The internal buffer exceeds `maxBufferBytes` (default 256 MiB).
- The periodic flush interval `flushIntervalMs` ticks (default 10 ms).

```
await using writer = createTopicWriter(driver, {
  topic: topicName,
  producer: producerName,
  // Callback that is called when writer receives an acknowledgment for a message.
  onAck: (seqNo, status) => {
    console.log("ACK", seqNo, status);
  },
})

writer.write(Buffer.from("Hello, world!", "utf-8"));

// Get the latest seqNo confirmed by the server.
await writer.flush();
```

Rust

```rust
use ydb::{TopicWriterMessageBuilder, YdbResult};

writer
    .write_with_ack(
        TopicWriterMessageBuilder::default()
            .data(b"payload".to_vec())
            .build()?,
    )
    .await?;
```

Selecting a codec for message compression

For more details on using data compression for topics, see here.

C++

The message compression can be set on the write session creation with `Codec` and `CompressionLevel` settings. By default, GZIP codec is chosen.

Example of creating a write session with no data compression:

```
auto settings = NYdb::NTopic::TWriteSessionSettings()
  // other settings are set here
  .Codec(ECodec::RAW);

auto session = topicClient.CreateWriteSession(settings);
```

Write session allows sending a message compressed with other codec. For this use `WriteEncoded` method, specify codec used and original message byte size. The codec must be allowed in topic settings.

Go

By default, the SDK selects the codec automatically based on topic settings. In automatic mode, the SDK first sends one group of messages with each of the allowed codecs, then it sometimes tries to compress messages with all the available codecs, and then selects the codec that yields the smallest message size. If the list of allowed codecs for the topic is empty, the SDK makes automatic selection between Raw and Gzip codecs.

If necessary, a fixed codec can be set in the connection options. It will then be used and no measurements will be taken.

```
producerAndGroupID := "group-id"
writer, _ := db.Topic().StartWriter(producerAndGroupID, "topicName",
  topicoptions.WithMessageGroupID(producerAndGroupID),
  topicoptions.WithCodec(topictypes.CodecGzip),
)
```

Python

By default, the SDK selects the codec automatically based on topic settings. In automatic mode, the SDK first sends one group of messages with each of the allowed codecs, then it sometimes tries to compress messages with all the available codecs, and then selects the codec that yields the smallest message size. If the list of allowed codecs for the topic is empty, the SDK makes automatic selection between Raw and Gzip codecs.

If necessary, a fixed codec can be set in the connection options. It will then be used and no measurements will be taken.

```
writer = driver.topic_client.writer(topic_path,
    codec=ydb.TopicCodec.GZIP,
)
```

Java

```
String producerAndGroupID = "group-id";
WriterSettings settings = WriterSettings.newBuilder()
        .setTopicPath(topicPath)
        .setProducerId(producerAndGroupID)
        .setMessageGroupId(producerAndGroupID)
        .setCodec(Codec.ZSTD)
        .build();
```

JavaScript

```
await using writer = t.createWriter({
  codec: Codec.RAW,
});

await using writer = t.createWriter({
  codec: Codec.GZIP,
});

await using writer = t.createWriter({
  codec: Codec.LZOP,
});

await using writer = t.createWriter({
  codec: 10000, // CUSTOM (allowed range: 10000–19999)
});
```

Rust

Per-writer message compression codec is not configurable in the Rust SDK yet; messages are sent with the `Raw` codec.

This functionality is not currently supported.

Track progress or vote for Rust SDK support: ydb-rs-sdk#341

Writing messages in no-deduplication mode

C++\nIf no ProducerId is specified on write session setup, the session runs in no-deduplication mode. The example below demonstrates such a session setup:

```
auto settings = NYdb::NTopic::TWriteSessionSettings()
    .Path(myTopicPath);
auto session = topicClient.CreateWriteSession(settings);
```

If, on other hand, you want to ensure deduplication is enabled, you can specify the ProducerId option or call the `DeduplicationEnabled()` method from WriteSessionSettings. The 'Connecting to a topic for message writes' section has an example of write session that has deduplication enabled.

Go\nIn **ydb-go-sdk, when you create a writer without explicitly passing `topicoptions.WithWriterProducerID`, the SDK still assigns a producer ID (it generates one automatically). A mode equivalent to omitting `ProducerId` in the C++ example above is not available in the current SDK version.**

Java\nThis functionality is not currently supported.

Python

This functionality is not currently supported.

C#

This functionality is not currently supported.

JavaScript

This functionality is not currently supported.

Rust

This functionality is not currently supported.

Track progress or vote for Rust SDK support: ydb-rs-sdk#341

PHP

This functionality is not currently supported.

Using message metadata feature

You can provide some metadata for any particular message when writing. This metadata can be a list of up to 1000 key-value pairs per message.
All the metadata provided when writing a message is sent to a consumer with the message during reading.

C++

To take advantage of message metadata feature, use the `Write()` method with `TWriteMessage` argument as below:

```
auto settings = NYdb::NTopic::TWriteSessionSettings()
    .Path(myTopicPath)
// set all other settings;
;

auto session = topicClient.CreateWriteSession(settings);

std::optional<NYdb::NTopic::TWriteSessionEvent::TEvent> event = session->GetEvent(/*block=*/true);
NYdb::NTopic::TWriteMessage message("This is yet another message").MessageMeta({
    {"meta-key", "meta-value"},
    {"another-key", "value"}
});

if (auto* readyEvent = std::get_if<NYdb::NTopic::TWriteSessionEvent::TReadyToAcceptEvent>(&*event)) {
    session->Write(std::move(event.ContinuationToken), std::move(message));
};
```

Java

Construct messages with the builder to take advantage of the message metadata feature. You can add `MetadataItem` objects to a message. Each item consists of a key of type `String` and a value of type `byte[]`.

`MetadataItem`s can be set as a `List`:

```
List<MetadataItem> metadataItems = Arrays.asList(
        new MetadataItem("meta-key", "meta-value".getBytes()),
        new MetadataItem("another-key", "value".getBytes())
);
writer.send(
        Message.newBuilder()
                .setMetadataItems(metadataItems)
                .build()
);
```

Or each `MetadataItem` can be added individually:

```
writer.send(
        Message.newBuilder()
                .addMetadataItem(new MetadataItem("meta-key", "meta-value".getBytes()))
                .addMetadataItem(new MetadataItem("another-key", "value".getBytes()))
                .build()
);
```

While reading, metadata can be received from a `Message` with the `getMetadataItems()` method:

```
Message message = reader.receive();
List<MetadataItem> metadata = message.getMetadataItems();
```

Python

To write a message that includes metadata, create the `TopicWriterMessage` object with the `metadata_items` argument as shown below:

```
message = ydb.TopicWriterMessage(data=f"message-data", metadata_items={"meta-key": "meta-value"})
writer.write(message)
```

While reading, retrieve metadata from the `metadata_items` field of the `PublicMessage` object:

```
message = reader.receive_message()
for meta_key, meta_value in message.metadata_items.items():
    print(f"{meta_key}: {meta_value}")
```

C#

```
await writer.WriteAsync(
    new Ydb.Sdk.Services.Topic.Writer.Message<string>("Hello Example YDB Topics!")
        { Metadata = { new Metadata("meta-key", "meta-value"u8.ToArray()) } }
);
```

Go

Set metadata in the `Metadata` field of `topicwriter.Message`:

```
err := writer.Write(ctx, topicwriter.Message{
  Data: strings.NewReader("message-data"),
  Metadata: map[string][]byte{
    "meta-key":    []byte("meta-value"),
    "another-key": []byte("value"),
  },
})
```

When reading, metadata is available on the message:

```
msg, err := reader.ReadMessage(ctx)
if err != nil {
  return err
}
for k, v := range msg.Metadata {
  fmt.Printf("%s: %s\n", k, string(v))
}
```

JavaScript

```
writer.write(Buffer.from("Hello, world!", "utf-8"), {
  metadataItems: {
    "meta-key": new TextEncoder().encode("meta-value"),
  },
});
```

Rust

This functionality is not currently supported.

Track progress or vote for Rust SDK support: ydb-rs-sdk#341

Write in a transaction

C++

To write to a topic within a transaction, it is necessary to pass a transaction object reference to the `Write` method of the writing session.

Example on GitHub

```
NYdb::NQuery::TQueryClient queryClient(driver);

NYdb::NStatusHelpers::ThrowOnError(queryClient.RetryQuerySync([](NYdb::NQuery::TSession session) -> NYdb::TSt
atus {
    auto beginTxResult = session.BeginTransaction().GetValueSync();
    if (!beginTxResult.IsSuccess()) {
        return beginTxResult;
    }
    auto tx = beginTxResult.GetTransaction();

    NYdb::NTopic::TWriteMessage writeMessage("message");

    topicSession->Write(std::move(writeMessage), tx);
    return tx.Commit().GetValueSync();
}));
```

Go

To write to a topic within a transaction, create a transactional writer by calling TopicClient.StartTransactionalWriter with the `tx` argument. Once created, you can send messages as usual. There's no need to close the transactional writer manually, as it will be closed automatically when the transaction ends.

Example on GitHub

```
err := db.Query().DoTx(ctx, func(ctx context.Context, tx query.TxActor) error {
  writer, err := db.Topic().StartTransactionalWriter(tx, topicName)
  if err != nil {
    return err
  }

  return writer.Write(ctx, topicwriter.Message{Data: strings.NewReader("asd")})
})
```

Python

To write to a topic within a transaction, create a transactional writer by calling `topic_client.tx_writer` with the `tx` argument. Once created, you can send messages as usual. There's no need to close the transactional writer manually, as it will be closed automatically when the transaction ends.

In the example below, there is no explicit call to `tx.commit()`; it occurs implicitly upon the successful execution of the `callee` lambda.

Example on GitHub

```
with ydb.QuerySessionPool(driver) as session_pool:

    def callee(tx: ydb.QueryTxContext):
        tx_writer: ydb.TopicTxWriter = driver.topic_client.tx_writer(tx, topic)

        for i in range(message_count):
            result_stream = tx.execute(query=f"select {i} as res;")
            for result_set in result_stream:
                message = str(result_set.rows[0]["res"])
                tx_writer.write(ydb.TopicWriterMessage(message))
                print(f"Message {message} was written with tx.")

    session_pool.retry_tx_sync(callee)
```

Python (asyncio)

To write to a topic within a transaction, create a transactional writer by calling `topic_client.tx_writer` with the `tx` argument. Once created, you can send messages as usual. There's no need to close the transactional writer manually, as it will be closed automatically when the transaction ends.

In the example below, there is no explicit call to `tx.commit()`; it occurs implicitly upon the successful execution of the `callee` lambda.

Example on GitHub

```
async with ydb.aio.QuerySessionPool(driver) as session_pool:

    async def callee(tx: ydb.aio.QueryTxContext):
        tx_writer: ydb.TopicTxWriterAsyncIO = driver.topic_client.tx_writer(tx, topic)

        for i in range(message_count):
            async with await tx.execute(query=f"select {i} as res;") as result_stream:
                async for result_set in result_stream:
                    message = str(result_set.rows[0]["res"])
                    await tx_writer.write(ydb.TopicWriterMessage(message))
                    print(f"Message {result_set.rows[0]['res']} was written with tx.")

    await session_pool.retry_tx_async(callee)
```

Java

Synchronous API

Example on GitHub

You can pass a transaction in `SendSettings` for the `send` method.
The message is then written together with that transaction's commit.

```
// creating a session in the table service
Result<Session> sessionResult = tableClient.createSession(Duration.ofSeconds(10)).join();
if (!sessionResult.isSuccess()) {
    logger.error("Couldn't get a session from the pool: {}", sessionResult);
    return; // retry or shutdown
}
Session session = sessionResult.getValue();
// creating a transaction in the table service
// this transaction is not yet active and has no id
TableTransaction transaction = session.createNewTransaction(TxMode.SERIALIZABLE_RW);

// get message text within the transaction
Result<DataQueryResult> dataQueryResult = transaction.executeDataQuery("SELECT \"Hello, world!\";")
        .join();
if (!dataQueryResult.isSuccess()) {
    logger.error("Couldn't execute DataQuery: {}", dataQueryResult);
    return; // retry or shutdown
}
// now the transaction is active and has an id

ResultSetReader rsReader = dataQueryResult.getValue().getResultSet(0);
byte[] message;
if (rsReader.next()) {
    message = rsReader.getColumn(0).getBytes();
} else {
    return; // retry or shutdown
}

writer.send(
        Message.of(message),
        SendSettings.newBuilder()
                .setTransaction(transaction)
                .build()
);

// flush to wait until all messages reach server before commit
writer.flush();

Status commitStatus = transaction.commit().join();
analyzeCommitStatus(commitStatus);
```

Asynchronous API

Example on GitHub

You can pass a transaction in `SendSettings` for the `send` method.
The message is then written together with that transaction's commit.

```
// creating a session in the table service
Result<Session> sessionResult = tableClient.createSession(Duration.ofSeconds(10)).join();
if (!sessionResult.isSuccess()) {
    logger.error("Couldn't get a session from the pool: {}", sessionResult);
    return; // retry or shutdown
}
Session session = sessionResult.getValue();
// creating a transaction in the table service
// this transaction is not yet active and has no id
TableTransaction transaction = session.createNewTransaction(TxMode.SERIALIZABLE_RW);

// get message text within the transaction
Result<DataQueryResult> dataQueryResult = transaction.executeDataQuery("SELECT \"Hello, world!\";")
        .join();
if (!dataQueryResult.isSuccess()) {
    logger.error("Couldn't execute DataQuery: {}", dataQueryResult);
    return; // retry or shutdown
}
// now the transaction is active and has an id

ResultSetReader rsReader = dataQueryResult.getValue().getResultSet(0);
byte[] message;
if (rsReader.next()) {
    message = rsReader.getColumn(0).getBytes();
} else {
    return; // retry or shutdown
}

try {
    writer.send(Message.newBuilder()
                            .setData(message)
                            .build(),
                    SendSettings.newBuilder()
                            .setTransaction(transaction)
                            .build())
            .whenComplete((result, ex) -> {
                if (ex != null) {
                    logger.error("Exception while sending a message: ", ex);
                } else {
                    switch (result.getState()) {
                        case WRITTEN:
                            WriteAck.Details details = result.getDetails();
                            logger.info("Message was written successfully, offset: " + details.getOffset());
                            break;
                        case ALREADY_WRITTEN:
                            logger.info("Message has already been written");
                            break;
                        default:
                            break;
                    }
                }
            })
            // Waiting for the message to reach the server before committing the transaction
            .join();

    Status commitStatus = transaction.commit().join();
    analyzeCommitStatus(commitStatus);
} catch (QueueOverflowException exception) {
    logger.error("Queue overflow exception while sending a message{}: ", index, exception);
    // Send queue is full. Need to retry with backoff or skip
}
```

> **Note**
>
> Transaction requirements:
>
> - It should be an active transaction (that has an id) from one of YDB services. I.e., Table or Query.
> - Only the `SERIALIZABLE_RW` transaction isolation level is supported in the Topic Service.

Reading messages

Connecting to a topic for message reads

Reading messages from a topic can be done by specifying a Consumer associated with that topic, as well as without a Consumer. If a Consumer is not specified, the client application must calculate the offset for reading messages on its own. A more detailed example of reading without a Consumer is discussed in the relevant section.

A Consumer can be created on creating or altering a topic.
Topic can have several Consumers and for each of them server stores its own reading progress.

C++

The read session object with `IReadSession` interface is used to connect to one or more topics for reading.

For a full list of read session settings, see `TReadSessionSettings` class in the source code.

To establish a connection to the existing `my-topic` topic using the added `my-consumer` consumer, use the following code:

```
auto settings = NYdb::NTopic::TReadSessionSettings()
    .ConsumerName("my-consumer")
    .AppendTopics("my-topic");

auto session = topicClient.CreateReadSession(settings);
```

Go

To establish a connection to the existing `my-topic` topic using the added `my-consumer` consumer, use the following code:

```
reader, err := db.Topic().StartReader("my-consumer", topicoptions.ReadTopic("my-topic"))
if err != nil {
    return err
}
```

Python

To establish a connection to the existing `my-topic` topic using the added `my-consumer` consumer, use the following code:

```
reader = driver.topic_client.reader(topic="my-topic", consumer="my-consumer")
```

Java

Synchronous API

Reader settings initialization:

```
ReaderSettings settings = ReaderSettings.newBuilder()
        .setConsumerName(consumerName)
        .addTopic(TopicReadSettings.newBuilder()
                .setPath(topicPath)
                .setReadFrom(Instant.now().minus(Duration.ofHours(24))) // Optional
                .setMaxLag(Duration.ofMinutes(30)) // Optional
                .build())
        .build();
```

Sync reader creation:

```
SyncReader reader = topicClient.createSyncReader(settings);
```

After a reader is created, initialize it. The sync reader supports two methods:

- `init()`: non-blocking; starts initialization in the background and does not wait for completion.

  ```
  reader.init();
  ```

- `initAndWait()`: blocking; waits for initialization. On failure, an exception is thrown.

  ```
  try {
      reader.initAndWait();
      logger.info("Init finished successfully");
  } catch (Exception exception) {
      logger.error("Exception while initializing reader: ", exception);
      return;
  }
  ```

Asynchronous API

Reader settings initialization:

```
ReaderSettings settings = ReaderSettings.newBuilder()
        .setConsumerName(consumerName)
        .addTopic(TopicReadSettings.newBuilder()
                .setPath(topicPath)
                .setReadFrom(Instant.now().minus(Duration.ofHours(24))) // Optional
                .setMaxLag(Duration.ofMinutes(30)) // Optional
                .build())
        .build();
```

For the async reader, provide `ReadEventHandlersSettings` with a `ReadEventHandler` implementation that defines how events are handled while reading.

```
ReadEventHandlersSettings handlerSettings = ReadEventHandlersSettings.newBuilder()
    .setEventHandler(new Handler())
    .build();
```

Optionally, specify an executor for message handling in `ReadEventHandlersSettings`.
You can subclass `AbstractReadEventHandler` and override `onMessages`. Example:

```
private class Handler extends AbstractReadEventHandler {
    @Override
    public void onMessages(DataReceivedEvent event) {
        for (Message message : event.getMessages()) {
            StringBuilder str = new StringBuilder();
            logger.info("Message received. SeqNo={}, offset={}", message.getSeqNo(), message.getOffset());

            process(message);

            message.commit().thenRun(() -> {
                logger.info("Message committed");
            });
        }
    }
}
```

Async reader creation and initialization:

```
AsyncReader reader = topicClient.createAsyncReader(readerSettings, handlerSettings);
// Init in background
reader.init()
        .thenRun(() -> logger.info("Init finished successfully"))
        .exceptionally(ex -> {
            logger.error("Init failed with ex: ", ex);
            return null;
        });
```

C#

```
await using var reader = new ReaderBuilder<string>(driver)
{
    ConsumerName = "Consumer_Example",
    SubscribeSettings = { new SubscribeSettings(topicName) }
}.Build();
```

JavaScript

```
await using reader = createTopicReader(driver, {
  topic: topicName,
  consumer: consumerName,
});
```

Rust

```
use ydb::YdbResult;

let mut reader = topic_client
    .create_reader("my-consumer", "/local/my-topic")
    .await?;
```

Additional options are used to specify multiple topics and other parameters.
To establish a connection to the `my-topic` and `my-specific-topic` topics using the `my-consumer` consumer and also set the time to start reading messages, use the following code:

C++

```
auto settings = NYdb::NTopic::TReadSessionSettings()
    .ConsumerName("my-consumer")
    .AppendTopics("my-topic")
    .AppendTopics(
        NYdb::NTopic::TTopicReadSettings("my-specific-topic")
            .ReadFromTimestamp(someTimestamp)
    );

auto session = topicClient.CreateReadSession(settings);
```

Go

```
reader, err := db.Topic().StartReader("my-consumer", []topicoptions.ReadSelector{
    {
        Path: "my-topic",
    },
    {
        Path:       "my-specific-topic",
        ReadFrom:   time.Date(2022, 7, 1, 10, 15, 0, 0, time.UTC),
    },
    },
)
if err != nil {
    return err
}
```

Python

This feature is under development.

Java

```
ReaderSettings settings = ReaderSettings.newBuilder()
        .setConsumerName(consumerName)
        .addTopic(TopicReadSettings.newBuilder()
                .setPath("my-topic")
                .build())
        .addTopic(TopicReadSettings.newBuilder()
                .setPath("my-specific-topic")
                .setReadFrom(Instant.now().minus(Duration.ofHours(24))) // Optional
                .setMaxLag(Duration.ofMinutes(30)) // Optional
                .build())
        .build();
```

C#

```
await using var reader = new ReaderBuilder<string>(driver)
{
    ConsumerName = "Consumer_Example",
    SubscribeSettings =
    {
        new SubscribeSettings(topicName),
        new SubscribeSettings(topicName + "_another") { ReadFrom = DateTime.Now }
    }
}.Build();
```

JavaScript

```
await using reader = createTopicReader(driver, {
  topic: {
    path: topicPath,
    partitionIds: [1n, 2n, 3n],
  },
  consumer: consumerName,
});

await using reader = createTopicReader(driver, {
  topic: {
    path: topicPath,
    maxLag: "1s", // number, import('ms').StringValue, protobuf Duration
  },
  consumer: consumerName,
});

await using reader = createTopicReader(driver, {
  topic: {
    path: topicPath,
    readFrom: new Date(), // number, Date, protobuf Timestamp
  },
  consumer: consumerName,
});

await using reader = createTopicReader(driver, {
  topic: [
    {
      path: topicPath,
      partitionIds: [1n, 2n, 3n],
    },
    {
      path: topicPath2,
      maxLag: "1s",
    },
    {
      path: topicPath3,
      readFrom: new Date(),
    },
    // ...
  ],
  consumer: consumerName,
});
```

Rust

```
use std::time::{Duration, SystemTime};

use ydb::{TopicReaderOptionsBuilder, TopicSelector, TopicSelectors, YdbResult};

let mut reader = topic_client
    .create_reader_with_params(
        TopicReaderOptionsBuilder::default()
            .consumer("my-consumer".into())
            .topic(TopicSelectors(vec![
                TopicSelector::new("/local/my-topic"),
                TopicSelector {
                    path: "/local/my-specific-topic".into(),
                    partition_ids: None,
                    read_from: Some(SystemTime::now() - Duration::from_secs(3600)),
                },
            ]))
            .build()?,
    )
    .await?;
```

Reading messages

The server stores the consumer offset. After reading a message, the client should send a commit to the server. The consumer offset changes and only uncommitted messages will be read in case of a new connection.

You can read messages without a commit as well. In this case, all uncommited messages, including those processed, will be read if there is a new connection.

Information about which messages have already been processed can be saved on the client side by sending the starting consumer offset to the server when creating a new connection. This does not change the consumer offset on the server.

Data from topics can be read in the context of transactions. In this case, the reading offset will only advance when the transaction is committed. On reconnect, all uncommitted messages will be read again.

C++

The user processes several kinds of events in a loop: `TDataReceivedEvent`, `TCommitOffsetAcknowledgementEvent`, `TStartPartitionSessionEvent`, `TStopPartitionSessionEvent`, `TPartitionSessionStatusEvent`, `TPartitionSessionClosedEvent` and `TSessionClosedEvent`.

For each kind of event user can set a handler in read session settings before session creation. Also, a common handler can be set.

If handler is not set for a particular event, it will be delivered to SDK client via `GetEvent` / `GetEvents` methods. The `WaitEvent` method allows user to await for a next event in non-blocking way with `TFuture<void>()` interface.

Go

The SDK receives data from the server in batches and buffers it. Depending on the task, the client code can read messages from the buffer one by one or in batches.

Python

The SDK receives data from the server in batches and buffers it. Depending on the task, the client code can read messages from the buffer one by one or in batches.

Java

The SDK receives data from the server in batches and buffers it. Depending on the task, the client code can read messages from the buffer one by one or in batches.

C#

The SDK receives data from the server in batches and buffers it. Depending on the task, the client code can read messages from the buffer one by one or in batches.

JavaScript

This section is under development.

Rust

Full example of reading a topic in a transaction with table writes: `topic-read-in-transaction-example.rs`.

```
let batch = reader.pop_batch_in_tx(&mut tx).await?;
// process batch.messages and commit the transaction
```

Reading without a commit

Reading messages one by one

C++

Reading messages one-by-one is not supported in the C++ SDK. Class `TDataReceivedEvent` represents a batch of read messages.

Go

```
func SimpleReadMessages(ctx context.Context, r *topicreader.Reader) error {
    for {
        mess, err := r.ReadMessage(ctx)
        if err != nil {
            return err
        }
        processMessage(mess)
    }
}
```

Python

Native SDK

```
while True:
    message = reader.receive_message()
    process(message)
```

Native SDK (Asyncio)

```
while True:
    message = await reader.receive_message()
    process(message)
```

Java

Synchronous API

To read messages one-by-one without commit, do not call `commit` on messages:

```
while(true) {
    Message message = reader.receive();
    process(message);
}
```

Asynchronous API

The async client does not support reading messages one-by-one.

C#

```
try
{
    while (!readerCts.IsCancellationRequested)
    {
        var message = await reader.ReadAsync(readerCts.Token);

        logger.LogInformation("Received message: [{MessageData}]", message.Data);
    }
}
catch (OperationCanceledException)
{
}
```

JavaScript

```
for await (let batch of reader.read()) {
  for await (let msg of batch) {
  }
}
```

Rust

This functionality is not currently supported.

Track progress or vote for Rust SDK support: ydb-rs-sdk#330

Reading message batches

C++

One simple way to read messages is to use `SimpleDataHandlers` setting when creating a read session. With it you only set a handler for a `TDataReceivedEvent`. SDK will call it for each batch of messages that came from server. By default, SDK does not send back acknowledgments of successful reads.

```
auto settings = NYdb::NTopic::TReadSessionSettings()
    .EventHandlers_.SimpleDataHandlers(
        [](NYdb::NTopic::TReadSessionEvent::TDataReceivedEvent& event) {
            std::cout << "Get data event " << NYdb::NTopic::DebugString(event);
        }
    );

auto session = topicClient.CreateReadSession(settings);

// Wait SessionClosed event.
session->GetEvent(/* block = */true);
```

In this example client creates read session and just awaits session close in the main thread. All other event types are handled by SDK.

Go

```
func SimpleReadBatches(ctx context.Context, r *topicreader.Reader) error {
    for {
        batch, err := r.ReadMessageBatch(ctx)
        if err != nil {
            return err
        }
        processBatch(batch)
    }
}
```

Python

Native SDK

```
while True:
    batch = reader.receive_batch()
    process(batch)
```

Native SDK (Asyncio)

```
while True:
    batch = await reader.receive_batch()
    process(batch)
```

JavaScript

```
for await (let batch of reader.read()) {
}
```

Java

Synchronous API

Batch reading is not supported in the sync reader.

Asynchronous API

To read without commit, do not call `commit`:

```
private class Handler extends AbstractReadEventHandler {
    @Override
    public void onMessages(DataReceivedEvent event) {
        for (Message message : event.getMessages()) {
            process(message);
        }
    }
}
```

C#

```
try
{
    while (!readerCts.IsCancellationRequested)
    {
        var batchMessages = await reader.ReadBatchAsync(readerCts.Token);

        foreach (var message in batchMessages.Batch)
        {
            logger.LogInformation("Received message: [{MessageData}]", message.Data);
        }
    }
}
catch (OperationCanceledException)
{
}
```

Rust

This functionality is not currently supported.

Track progress or vote for Rust SDK support: ydb-rs-sdk#330

Reading with a commit

Confirmation of message processing (commit) informs the server that the message from the topic has been processed by the recipient and does not need to be sent anymore. When using acknowledged reading, it is necessary to confirm all received messages without skipping any. Message commits on the server occur after confirming a consecutive interval of messages "without gaps," and the confirmations themselves can be sent in any order.

For example, if messages 1, 2, 3 are received from the server, the program processes them in parallel and sends confirmations in the following order: 1, 3, 2. In this case, message 1 will be committed first, and messages 2 and 3 will be committed only after the server receives confirmation of the processing of message 2.

If a commit fails with an error, the application should log it and continue; it makes no sense to retry the commit. At this point, it is not known if the message was actually confirmed.

Reading messages one by one with commits

C++

Reading messages one-by-one is not supported in the C++ SDK. Class `TDataReceivedEvent` represents a batch of read messages.

Go

```
func SimpleReadMessages(ctx context.Context, r *topicreader.Reader) error {
    for {
      mess, err := r.ReadMessage(ctx)
      if err != nil {
          return err
      }
      processMessage(mess)
      r.Commit(mess.Context(), mess)
    }
}
```

The `Commit` call is fast by default, saving data into an internal buffer and returning control to the caller. The real message to the server is sent in the background. To prevent losing the last commits, call the `Reader.Close()` method before exiting the program.

Python

The `commit` call is fast, saving data into an internal buffer and returning control back to the caller. The real message to the server is sent in the background. To prevent losing the last commits, you should call the `Reader.Close()` method before exiting the program.

Native SDK

```
while True:
    message = reader.receive_message()
    process(message)
    reader.commit(message)
```

Native SDK (Asyncio)

```
while True:
    message = await reader.receive_message()
    process(message)
    reader.commit(message)
```

Java

To commit a message just call `commit` method on it.
This method returns `CompletableFuture<Void>` which successful completion means that the server confirmed commit.
In case of an error on commit do not retry it. Most likely, an error is caused be session shutdown.
The reader (maybe another one) will create a new session for this partition and the message will be read again.

```
message.commit()
       .whenComplete((result, ex) -> {
           if (ex != null) {
               // Read session was probably closed, there is nothing we can do here.
               // Do not retry this commit on the same message.
               logger.error("exception while committing message: ", ex);
           } else {
               logger.info("message committed successfully");
           }
       });
```

C#

```
try
{
    while (!readerCts.IsCancellationRequested)
    {
        var message = await reader.ReadAsync(readerCts.Token);

        logger.LogInformation("Received message: [{MessageData}]", message.Data);

        try
        {
            await message.CommitAsync();
        }
        catch (ReaderException e)
        {
            logger.LogError(e, "Failed to commit a message");
        }
    }
}
catch (OperationCanceledException)
{
}
```

JavaScript

```
for await (let batch of reader.read()) {
  for (let msg of batch) {
    await reader.commit(msg);
  }
}
```

Reading message batches with commits

C++

Same as above example, when using `SimpleDataHandlers` handlers you only set handler for a `TDataReceivedEvent`. SDK will call it for each batch of messages that came from server. By setting `commitDataAfterProcessing = true`, you tell SDK to send back commits after executing a handler for corresponding event.

```
auto settings = NYdb::NTopic::TReadSessionSettings()
    .EventHandlers_.SimpleDataHandlers(
        [](NYdb::NTopic::TReadSessionEvent::TDataReceivedEvent& event) {
            std::cout << "Get data event " << NYdb::NTopic::DebugString(event);
        }
        , /* commitDataAfterProcessing = */true
    );

auto session = topicClient.CreateReadSession(settings);

// Wait SessionClosed event.
session->GetEvent(/* block = */true);
```

Go

```
func SimpleReadMessageBatch(ctx context.Context, r *topicreader.Reader) error {
    for {
      batch, err := r.ReadMessageBatch(ctx)
      if err != nil {
          return err
      }
      processBatch(batch)
      r.Commit(batch.Context(), batch)
    }
}
```

The `Commit` call is fast by default, saving data into an internal buffer and returning control back to the caller. The real message to the server is sent in the background. To prevent losing the last commits, you should call the `Reader.Close()` method before exiting the program.

Python

Native SDK

```
while True:
    batch = reader.receive_batch()
    process(batch)
    reader.commit(batch)
```

Native SDK (Asyncio)

```
while True:
    batch = await reader.receive_batch()
    process(batch)
    reader.commit(batch)
```

The `commit` call is fast, saving data into an internal buffer and returning control back to the caller. The real message to the server is sent in the background. To prevent losing the last commits, you should call the `Reader.Close()` method before exiting the program.

Java

Synchronous API

Not applicable: the sync reader does not support batch reads.

Asynchronous API

In `onMessages`, commit the whole batch in `DataReceivedEvent`:

```
@Override
public void onMessages(DataReceivedEvent event) {
    for (Message message : event.getMessages()) {
        process(message);
    }
    event.commit()
           .whenComplete((result, ex) -> {
               if (ex != null) {
                   // Read session was probably closed, there is nothing we can do here.
                   // Do not retry this commit on the same event.
                   logger.error("exception while committing message batch: ", ex);
               } else {
                   logger.info("message batch committed successfully");
               }
           });
}
```

C#

```
try
{
    while (!readerCts.IsCancellationRequested)
    {
        var batchMessages = await reader.ReadBatchAsync(readerCts.Token);

        foreach (var message in batchMessages.Batch)
        {
            logger.LogInformation("Received message: [{MessageData}]", message.Data);
        }

        try
        {
            await batchMessages.CommitBatchAsync();
        }
        catch (ReaderException e)
        {
            logger.LogError(e, "Failed to commit a message");
        }
    }
}
catch (OperationCanceledException)
{
}
```

JavaScript

```
for await (let batch of reader.read()) {
  await reader.commit(batch);
}
```

Rust

```
let batch = reader.read_batch().await?;
reader.commit(batch.get_commit_marker())?;
// or with waiting for server acknowledgment:
reader.commit_with_ack(batch.get_commit_marker()).await?;
```

Reading with consumer offset storage on the client side

Instead of committing messages, the client application may track reading progress on its own. In this case, it can provide a handler, which will be called back on each partition read start. This handler may set a starting reading position for this partition.

C++

The starting position of a specific partition read can be set during `TStartPartitionSessionEvent` handling.
For this purpose, `TStartPartitionSessionEvent::Confirm` has a `readOffset` parameter.
Additionally, there is a `commitOffset` parameter that tells the server to consider all messages with lesser offsets committed.

Setting handler example:

```
settings.EventHandlers_.StartPartitionSessionHandler(
    [](NYdb::NTopic::TReadSessionEvent::TStartPartitionSessionEvent& event) {
        auto readFromOffset = GetOffsetToReadFrom(event.GetPartitionId());
        event.Confirm(readFromOffset);
    }
);
```

In the code above, `GetOffsetToReadFrom` is part of the example, not SDK. Use your own method to provide the correct starting offset for a partition with a given partition id.

Also, `TReadSessionSettings` has a `ReadFromTimestamp` setting for reading only messages newer than the given timestamp. This setting is intended to skip some messages, not for precise reading start positioning. Several first-received messages may still have timestamps less than the specified one.

Go

```
func ReadWithExplicitPartitionStartStopHandlerAndOwnReadProgressStorage(ctx context.Context, db ydb.Connectio
n) error {
    readContext, stopReader := context.WithCancel(context.Background())
    defer stopReader()

    readStartPosition := func(
        ctx context.Context,
        req topicoptions.GetPartitionStartOffsetRequest,
    ) (res topicoptions.GetPartitionStartOffsetResponse, err error) {
        offset, err := readLastOffsetFromDB(ctx, req.Topic, req.PartitionID)
        res.StartFrom(offset)

        // Reader will stop if return err != nil
        return res, err
    }

    r, err := db.Topic().StartReader("my-consumer", topicoptions.ReadTopic("my-topic"),
        topicoptions.WithGetPartitionStartOffset(readStartPosition),
    )
    if err != nil {
        return err
    }

    go func() {
        <-readContext.Done()
        _ = r.Close(ctx)
    }()

    for {
        batch, err := r.ReadMessageBatch(readContext)
        if err != nil {
            return err
        }

        processBatch(batch)
        _ = externalSystemCommit(batch.Context(), batch.Topic(), batch.PartitionID(), batch.EndOffset())
    }
}
```

Python

This feature is under development.

Java

The starting offset for reading in Java can only be set for AsyncReader.
In `StartPartitionSessionEvent`, a `StartPartitionSessionSettings` object with the desired ReadOffset can be passed to the `confirm` method.
The offset that should be considered as committed can be set with the `setCommittedOffset` method.

```
@Override
public void onStartPartitionSession(StartPartitionSessionEvent event) {
    event.confirm(StartPartitionSessionSettings.newBuilder()
            .setReadOffset(lastReadOffset) // Long
            .setCommitOffset(lastCommitOffset) // Long
            .build());
}
```

The `setReadFrom` setting is used for reading only messages with write timestamps no less than the given one.

JavaScript

```
await using reader = createTopicReader(driver, {
  topic: topicName,
  consumer: consumerName,
  onPartitionSessionStart: (evt) => {
    return {
      readOffset: 0n,
      commitOffset: 0n,
    };
  },
});
```

Rust

This functionality is not currently supported.

Track progress or vote for Rust SDK support: ydb-rs-sdk#330

Reading without a Consumer

Reading progress is usually saved on a server for each Consumer. However, such progress can't be saved if a reader is created without a specified `Consumer`.

Go

Pass an empty string as the consumer name and use the `topicoptions.WithReaderWithoutConsumer(false)` option (this mode is **experimental**; see VERSIONING in the SDK repository). In the read selector, specify the topic path and partition list. Message commits are not available in this mode (`CommitModeNone`); on reconnects you must restore progress on the client side—see client-side offset storage.

```
reader, err := db.Topic().StartReader(
  "",
  topicoptions.ReadSelectors{{
    Path:       "topic-path",
    Partitions: []int64{0, 1, 2},
  }},
  topicoptions.WithReaderWithoutConsumer(false),
)
if err != nil {
  return err
}
```

Java

To read without a Consumer, the `withoutConsumer()` method should be called explicitly on the `ReaderSettings` builder:

```
ReaderSettings settings = ReaderSettings.newBuilder()
        .withoutConsumer()
        .addTopic(TopicReadSettings.newBuilder()
                .setPath(TOPIC_NAME)
                .build())
        .build();
```

In this case, reading progress on the server will be lost on partition session restart.
To avoid reading from the beginning each time, starting offsets should be set on each partition session start:

```
@Override
public void onStartPartitionSession(StartPartitionSessionEvent event) {
    event.confirm(StartPartitionSessionSettings.newBuilder()
            .setReadOffset(lastReadOffset) // the last offset read by this client, Long
            .build());
}
```

Python

To read without a `Consumer`, create a reader using the `reader` method with specifying these arguments:

- `topic` - `ydb.TopicReaderSelector` object with defined `path` and `partitions` list;
- `consumer` - should be `None`;
- `event_handler` - inheritor of `ydb.TopicReaderEvents.EventHandler` that implements the `on_partition_get_start_offset` function. This function is responsible for returning the initial offset for reading messages when the reader starts and during reconnections. The client application must specify this offset in the parameter `ydb.TopicReaderEvents.OnPartitionGetStartOffsetResponse.start_offset`. The function can also be implemented as asynchronous.

Example:

```
class CustomEventHandler(ydb.TopicReaderEvents.EventHandler):
    def on_partition_get_start_offset(self, event: ydb.TopicReaderEvents.OnPartitionGetStartOffsetRequest):
        return ydb.TopicReaderEvents.OnPartitionGetStartOffsetResponse(
            start_offset=0,
        )

reader = driver.topic_client.reader(
    topic=ydb.TopicReaderSelector(
        path="topic-path",
        partitions=[0, 1, 2],
    ),
    consumer=None,
    event_handler=CustomEventHandler(),
)
```

JavaScript

This section is under development.

Rust

This functionality is not currently supported.

Track progress or vote for Rust SDK support: ydb-rs-sdk#330

Reading in a transaction

C++

Before reading messages, the client code must pass a transaction object reference to the reading session settings.

Example on GitHub

```
readSession->WaitEvent().Wait(TDuration::Seconds(1));

NYdb::NStatusHelpers::ThrowOnError(queryClient.RetryQuerySync([&readSession](NYdb::NQuery::TSession session)
-> NYdb::TStatus {
    auto beginTxResult = session.BeginTransaction(NYdb::Query::TTxSettings::SerializableRW()).GetValueSync();
    if (!beginTxResult.IsSuccess()) {
        return beginTxResult;
    }
    auto tx = beginTxResult.GetTransaction();

    auto topicSettings = NYdb::NTopic::TReadSessionGetEventSettings()
        .Block(false);
        .Tx(tx);

    auto events = readSession->GetEvents(topicSettings);

    for (auto& event : events) {
        // process the event and write results to a table
    }

    return tx.Commit().GetValueSync();
}));
```

> **Warning**
>
> When processing `events`, you do not need to confirm processing for `TDataReceivedEvent` events explicitly.

Confirmation of the `TStopPartitionSessionEvent` event processing must be done after calling `Commit`.

```
std::optional<NYdb::NTopic::TStopPartitionSessionEvent> stopPartitionSession;

auto events = readSession->GetEvents(topicSettings);

for (auto& event : events) {
    if (auto* e = std::get_if<NYdb::NTopic::TStopPartitionSessionEvent>(&event)) {
        stopPartitionSessionEvent = std::move(*e);
    } else {
        // process the event and write results to a table
    }
}

auto commitResult = tx.Commit(commitSettings).GetValueSync();
if (!commitResult.IsSuccess()) {
    return commitResult;
}

if (stopPartitionSessionEvent) {
    stopPartitionSessionEvent->Commit();
}
```

Go

To read messages from a topic within a transaction, use the Reader.PopMessagesBatchTx method. It reads a batch of messages and adds their commit to the transaction, so there's no need to commit them separately. The reader can be reused across different transactions. However, it's important to commit transactions in the same order as the messages are read from the reader, as message commits in the topic must be performed strictly in order. The simplest way to ensure this is by using the reader within a loop.

Example on GitHub

```
for {
  err := db.Query().DoTx(ctx, func(ctx context.Context, tx query.TxActor) error {
    batch, err := reader.PopMessagesBatchTx(ctx, tx) // the batch will be committed along with the transactio
n
    if err != nil {
      return err
    }

    return processBatch(ctx, batch)
  })
  if err != nil {
    handleError(err)
  }
}
```

Python

To read messages from a topic within a transaction, use the `reader.receive_batch_with_tx` method. It reads a batch of messages and adds their commit to the transaction, so there's no need to commit them separately. The reader can be reused across different transactions. However, it's essential to commit transactions in the same order as the messages are read from the reader, as message commits in the topic must be performed strictly in order - otherwise transaction will get an error during commit. The simplest way to ensure this is by using the reader within a loop.

Native SDK

Example on GitHub

```
with driver.topic_client.reader(topic, consumer) as reader:
    with ydb.QuerySessionPool(driver) as session_pool:
        for _ in range(message_count):

            def callee(tx: ydb.QueryTxContext):
                batch = reader.receive_batch_with_tx(tx, max_messages=1)
                print(f"Message {batch.messages[0].data.decode()} was read with tx.")

            session_pool.retry_tx_sync(callee)
```

Native SDK (Asyncio)

Example on GitHub

```
async with driver.topic_client.reader(topic, consumer) as reader:
    async with ydb.aio.QuerySessionPool(driver) as session_pool:
        for _ in range(message_count):

            async def callee(tx: ydb.aio.QueryTxContext):
                batch = await reader.receive_batch_with_tx(tx, max_messages=1)
                print(f"Message {batch.messages[0].data.decode()} was read with tx.")

            await session_pool.retry_tx_async(callee)
```

Java

Synchronous API

Example on GitHub

You can pass a transaction in `ReceiveSettings` for `receive`:

```
Message message = reader.receive(ReceiveSettings.newBuilder()
        .setTransaction(transaction)
        .build());
```

The message is then committed together with that transaction; do not commit it separately.
`receive` links message offsets to the transaction on the server via `sendUpdateOffsetsInTransaction` and returns after the response arrives.

Asynchronous API

Example on GitHub

In `onMessages`, you can attach one or more messages to a transaction by calling `reader.updateOffsetsInTransaction`.
Wait for that call to finish before committing the transaction.
The method takes a partition offset list; you can build it manually or use `getPartitionOffsets()` on `Message` or `DataReceivedEvent`.

```
@Override
public void onMessages(DataReceivedEvent event) {
    for (Message message : event.getMessages()) {
        // creating a session in the table service
        Result<Session> sessionResult = tableClient.createSession(Duration.ofSeconds(10)).join();
        if (!sessionResult.isSuccess()) {
            logger.error("Couldn't get a session from the pool: {}", sessionResult);
            return; // retry or shutdown
        }
        Session session = sessionResult.getValue();
        // creating a transaction in the table service
        // this transaction is not yet active and has no id
        TableTransaction transaction = session.createNewTransaction(TxMode.SERIALIZABLE_RW);

        // do something else in the transaction
        transaction.executeDataQuery("SELECT 1").join();
        // now the transaction is active and has an id
        // analyzeQueryResultIfNeeded();

        Status updateStatus = reader.updateOffsetsInTransaction(transaction,
                        message.getPartitionOffsets(), new UpdateOffsetsInTransactionSettings.Builder().build
())
                // Do not commit a transaction without waiting for updateOffsetsInTransaction result to avoid
a race condition
                .join();
        if (!updateStatus.isSuccess()) {
            logger.error("Couldn't update offsets in a transaction: {}", updateStatus);
            return; // retry or shutdown
        }

        Status commitStatus = transaction.commit().join();
        analyzeCommitStatus(commitStatus);
    }
}
```

Note

Transaction requirements:

- It should be an active transaction (that has an id) from one of YDB services. I.e., Table or Query.
- Only the `SERIALIZABLE_RW` transaction isolation level is supported in the Topic Service.

JavaScript

This section is under development.

Rust

Full example of reading a topic in a transaction with table writes: `topic-read-in-transaction-example.rs`.

```
let batch = reader.pop_batch_in_tx(&mut tx).await?;
// process batch.messages and commit the transaction
```

Processing a server read interrupt

YDB uses server-based partition balancing between clients. This means that the server can interrupt the reading of messages from random partitions.

In case of a *soft interruption*, the client receives a notification that the server has finished sending messages from the partition and messages will no longer be read. The client can finish processing messages and send a commit to the server.

In case of a *hard interruption*, the client receives a notification that it is no longer possible to work with partitions. The client must stop processing the read messages. Uncommited messages will be transferred to another consumer.

Soft reading interruption

C++

The `TStopPartitionSessionEvent` class is used for soft reading interruption. It helps user to stop message processing gracefully.

Example of event loop fragment:

```
auto event = readSession->GetEvent(/*block=*/true);
if (auto* stopPartitionSessionEvent = std::get_if<NYdb::NTopic::TReadSessionEvent::TStopPartitionSessionEvent
>(&*event)) {
    stopPartitionSessionEvent->Confirm();
} else {
  // other event types
}
```

Go

The client code immediately receives all messages from the buffer (on the SDK side) even if they are not enough to form a batch during batch processing.

```
r, _ := db.Topic().StartReader("my-consumer", nil,
    topicoptions.WithBatchReadMinCount(1000),
)

for {
    batch, _ := r.ReadMessageBatch(ctx) // <- if partition soft stop batch can be less, then 1000
    processBatch(batch)
    _ = r.Commit(batch.Context(), batch)
}
```

Python

No special processing is required.

Native SDK

```
while True:
    batch = reader.receive_batch()
    process(batch)
    reader.commit(batch)
```

Native SDK (Asyncio)

```
while True:
    batch = await reader.receive_batch()
    process(batch)
    reader.commit(batch)
```

Java

Synchronous API

Not applicable: the sync reader does not let you customize handling for this event.
The client automatically acknowledges stop to the server.

Asynchronous API

Override `onStopPartitionSession(StopPartitionSessionEvent event)` on your `ReadEventHandler` (see Connecting for reads). You must call `event.confirm()` so the server can continue shutdown.

```
@Override
public void onStopPartitionSession(StopPartitionSessionEvent event) {
    logger.info("Partition session {} stopped. Committed offset: {}", event.getPartitionSessionId(),
            event.getCommittedOffset());
    // This event means that no more messages will be received by server
    // Received messages still can be read from ReaderBuffer
    // Messages still can be committed, until confirm() method is called

    // Confirm that session can be closed
    event.confirm();
}
```

JavaScript

This section is under development.

Rust

The Rust SDK handles partition session stop and close events internally; there is no public API to customize soft or hard interruption handling yet.

This functionality is not currently supported.

Track progress or vote for Rust SDK support: ydb-rs-sdk#330

Hard reading interruption

C++

The hard interruption of reading messages is implemented using an `TPartitionSessionClosedEvent` event. It can be received either as soft interrupt confirmation response, or in the case of lost connection. The user can find out the reason for session closing using the `GetReason` method.

Example of event loop fragment:

```
auto event = readSession->GetEvent(/*block=*/true);
if (auto* partitionSessionClosedEvent = std::get_if<NYdb::NTopic::TReadSessionEvent::TPartitionSessionClosedE
vent>(&*event)) {
    if (partitionSessionClosedEvent->GetReason() == TPartitionSessionClosedEvent::EReason::ConnectionLost) {
        std::cout << "Connection with partition was lost" << std::endl;
    }
} else {
  // other event types
}
```

Go

When reading is interrupted, the message or message batch context is canceled.

```
ctx := batch.Context() // batch.Context() will cancel if partition revoke by server or connection broke
if len(batch.Messages) == 0 {
    return
}

buf := &bytes.Buffer{}
for _, mess := range batch.Messages {
    buf.Reset()
    _, _ = buf.ReadFrom(mess)
    _, _ = io.Copy(buf, mess)
    writeMessagesToDB(ctx, buf.Bytes())
}
```

Python

In this example, processing of messages within the batch will stop if the partition is reassigned during operation. This kind of optimization requires that you run extra code on the client side. In simple cases when processing of reassigned partitions is not a problem, you may skip this optimization.

Native SDK

```
def process_batch(batch):
    for message in batch.messages:
        if not batch.alive:
            return False
        process(message)
    return True

batch = reader.receive_batch()
if process_batch(batch):
    reader.commit(batch)
```

Native SDK (Asyncio)

```
def process_batch(batch):
    for message in batch.messages:
        if not batch.alive:
            return False
        process(message)
    return True

batch = await reader.receive_batch()
if process_batch(batch):
    reader.commit(batch)
```

Java

Synchronous API

Not applicable: the sync reader does not let you customize handling for this event.

Asynchronous API

```
@Override
public void onPartitionSessionClosed(PartitionSessionClosedEvent event) {
    logger.info("Partition session {} is closed.", event.getPartitionSession().getPartitionId());
}
```

JavaScript

This section is under development.

Rust

The Rust SDK handles partition session stop and close events internally; there is no public API to customize soft or hard interruption handling yet.

This functionality is not currently supported.

Track progress or vote for Rust SDK support: ydb-rs-sdk#330

Topic autoscaling

Go

Autoscaling of a topic can be enabled during its creation using the `topicoptions.CreateWithAutoPartitioningSettings` option:

```
import (
  ...

  "github.com/ydb-platform/ydb-go-sdk/v3/topic/topicoptions"
  "github.com/ydb-platform/ydb-go-sdk/v3/topic/topictypes"
)

err := db.Topic().Create(ctx,
  "topic",
  topicoptions.CreateWithAutoPartitioningSettings(
    topictypes.AutoPartitioningSettings{
      AutoPartitioningStrategy: topictypes.AutoPartitioningStrategyScaleUp,
    },
  ),
)
```

When needed, you can set additional parameters in AutoPartitioningSettings:

```
err := db.Topic().Create(ctx,
  "topic",
  topicoptions.CreateWithAutoPartitioningSettings(
    topictypes.AutoPartitioningSettings{
      AutoPartitioningStrategy: topictypes.AutoPartitioningStrategyScaleUp,
      AutoPartitioningWriteSpeedStrategy: topictypes.AutoPartitioningWriteSpeedStrategy{
        StabilizationWindow:    time.Minute,
        UpUtilizationPercent:   80,
      },
    },
  ),
)
```

Changes to an existing topic can be made using the `topicoptions.AlterWithAutoPartitioningStrategy` option with `.Topic().Alter`:

```
import (
  ...

  "github.com/ydb-platform/ydb-go-sdk/v3/topic/topicoptions"
  "github.com/ydb-platform/ydb-go-sdk/v3/topic/topictypes"
)

err := db.Topic().Alter(
  ctx,
  "topic",
  topicoptions.AlterWithAutoPartitioningStrategy(
    topictypes.AutoPartitioningStrategyScaleUp,
  ),
)

// other options
err := db.Topic().Alter(
  ctx,
  "topic",
  topicoptions.AlterWithAutoPartitioningStrategy(
    topictypes.AutoPartitioningStrategyScaleUp,
  ),
  topicoptions.AlterWithAutoPartitioningWriteSpeedStabilizationWindow(time.Minute),
  topicoptions.AlterWithAutoPartitioningWriteSpeedUpUtilizationPercent(80),
)
```

The SDK supports two topic reading modes with autoscaling enabled: full support mode and compatibility mode. The reading mode is set using the `topicoptions.WithReaderSupportSplitMergePartitions` option when creating the reader. Full support mode is used by default (`true`).

From a practical perspective, these modes do not differ for the end user. However, the full support mode differs from the compatibility mode in terms of who guarantees the order of reading—the client or the server. Compatibility mode is achieved through server-side processing and generally operates slower.

```
import (
  ...

  "github.com/ydb-platform/ydb-go-sdk/v3/topic/topicoptions"
  "github.com/ydb-platform/ydb-go-sdk/v3/topic/topictypes"
)

// full support mode (autoscaling processing in SDK, by default)
reader, err := db.Topic().StartReader(
  "consumer",
  topicoptions.ReadTopic("topic"),
  topicoptions.WithReaderSupportSplitMergePartitions(true),
)

// compatibility mode (autoscaling processing on server)
reader, err := db.Topic().StartReader(
  "consumer",
  topicoptions.ReadTopic("topic"),
  topicoptions.WithReaderSupportSplitMergePartitions(false),
)
```

Python

Autoscaling of a topic can be enabled during its creation using the `auto_partitioning_settings` argument of `create_topic`:

Native SDK

```
driver.topic_client.create_topic(
    topic,
    consumers=[consumer],
    min_active_partitions=10,
    max_active_partitions=100,
    auto_partitioning_settings=ydb.TopicAutoPartitioningSettings(
        strategy=ydb.TopicAutoPartitioningStrategy.SCALE_UP,
        up_utilization_percent=80,
        down_utilization_percent=20,
        stabilization_window=datetime.timedelta(seconds=300),
    ),
)
```

Native SDK (Asyncio)

```
await driver.topic_client.create_topic(
    topic,
    consumers=[consumer],
    min_active_partitions=10,
    max_active_partitions=100,
    auto_partitioning_settings=ydb.TopicAutoPartitioningSettings(
        strategy=ydb.TopicAutoPartitioningStrategy.SCALE_UP,
        up_utilization_percent=80,
        down_utilization_percent=20,
        stabilization_window=datetime.timedelta(seconds=300),
    ),
)
```

Changes to an existing topic can be made using the `alter_auto_partitioning_settings` argument of `alter_topic`:

```
driver.topic_client.alter_topic(
    topic_path,
    alter_auto_partitioning_settings=ydb.TopicAlterAutoPartitioningSettings(
        set_strategy=ydb.TopicAutoPartitioningStrategy.SCALE_UP,
        set_up_utilization_percent=80,
        set_down_utilization_percent=20,
        set_stabilization_window=datetime.timedelta(seconds=300),
    ),
)
```

The SDK supports two topic reading modes with autoscaling enabled: full support mode and compatibility mode. The reading mode can be set in the `auto_partitioning_support` argument when creating the reader. Full support mode is used by default.

```
reader = driver.topic_client.reader(
    topic,
    consumer,
    auto_partitioning_support=True, # Full support is enabled
)

# or

reader = driver.topic_client.reader(
    topic,
    consumer,
    auto_partitioning_support=False, # Compatibility mode is enabled
)
```

From a practical perspective, these modes do not differ for the end user. However, the full support mode differs from the compatibility mode in terms of who guarantees the order of reading—the client or the server. Compatibility mode is achieved through server-side processing and generally operates slower.

Rust

This functionality is not currently supported.

Track progress or vote for Rust SDK support: ydb-rs-sdk#311

Commit outside the reader

Most often, committing is conveniently done within the reader that has read the messages. However, there are scenarios where committing needs to be performed by a separate process. In such cases, a method of committing outside the reader is necessary.

Go

Committing outside the reader is done with `db.Topic().CommitOffset`:

```
// Basic usage — commit an offset without an active read session
err := db.Topic().CommitOffset(
  ctx,
  topicPath,
  partitionID,
  consumer,
  offset,
)
```

If a read session is active when you commit (via `StartReader` or `StartListener`), pass its ID with `WithCommitOffsetReadSessionID` so the server does not interrupt the current read session:

```
import (
  // ...
  "github.com/ydb-platform/ydb-go-sdk/v3/topic/topicoptions"
)

// Read session ID
sessionID := reader.ReadSessionID()
// or: sessionID := listener.ReadSessionID()

err = db.Topic().CommitOffset(
  ctx,
  topicPath,
  partitionID,
  consumer,
  offset,
  topicoptions.WithCommitOffsetReadSessionID(sessionID),
)
```

Python

Committing outside the reader is done with the `topic_client.commit_offset` method:

Native SDK

```
driver.topic_client.commit_offset(
    topic_path,
    consumer_name,
    partition_id,
    offset,
    reader.read_session_id,  # optional: avoids interrupting the active read session
)
```

Native SDK (Asyncio)

```
await driver.topic_client.commit_offset(
    topic_path,
    consumer_name,
    partition_id,
    offset,
    reader.read_session_id,  # optional: avoids interrupting the active read session
)
```

JavaScript

This section is under development.

Java

```
TopicClient client = ...;

String sessionID = reader.getSessionId();
// For AsyncReader, the session ID can be obtained when handling SessionStartedEvent

client.commitOffset(
    topicPath,
    CommitOffsetSettings.newBuilder()
        .setReadSessionId(sessionID)
        .setPartitionId(partitionID)
        .setConsumer(consumer)
        .setOffset(offset)
        .build()
).join().expectSuccess("Error commit!");
```

Rust

This functionality is not currently supported.

Working with coordination nodes

This article describes how to use the YDB SDK to coordinate the work of multiple client application instances using coordination nodes and their semaphores.

Creating a coordination node

Coordination nodes are created in YDB databases in the same namespace as other schema objects, such as tables and topics.

Go

```
err := db.Coordination().CreateNode(ctx,
    "/path/to/mynode",
)
```

C++

```
TClient client(driver);
auto status = client
    .CreateNode("/path/to/mynode")
    .ExtractValueSync();
Y_ABORT_UNLESS(status.IsSuccess());
```

When creating a node, you can optionally specify `TNodeSettings` with the following settings:

- `ReadConsistencyMode` - defaults to `RELAXED`, allowing the reading of potentially outdated values during leader transitions. You can optionally enable the `STRICT` mode, where all reads are processed through the consensus algorithm, ensuring the most recent value is returned, albeit at a higher cost.
- `AttachConsistencyMode` - defaults to `STRICT`, requiring the consensus algorithm for session recovery. Optionally, the `RELAXED` mode can be enabled for session recovery during failures, bypassing this requirement. This mode may be necessary for a large number of clients, facilitating session recovery without consensus, which maintains overall correctness but may lead to outdated reads during leader transitions and session expiration in problematic scenarios.
- `SelfCheckPeriod` (default 1 second) - the interval at which the service performs self-liveness checks. It is not recommended to change this setting except under special circumstances.
  - A larger value reduces server load but increases the delay in detecting leader changes and informing the service.
  - A smaller value increases server load and improves problem detection speed, but may result in false positives when the service incorrectly identifies issues.
- `SessionGracePeriod` (default 10 seconds) - the duration during which a new leader refrains from closing existing open sessions, prolonging their validity.
  - A smaller value reduces the window during which sessions from non-existent clients, which failed to report their absence during leader changes, hold semaphores and block other clients.
  - A smaller value also increases the likelihood of false positives, where a living leader might terminate itself as a precaution, uncertain if this period has concluded on a potential new leader.
  - This value must be strictly greater than `SelfCheckPeriod`.

Java

```
CoordinationClient client = CoordinationClient.newClient(transport);
```

Create a node by calling `createNode` with the full path to the node in the database. You can take the database path prefix from `client.getDatabase()`.

When needed, configure the node via NodeConfig using the `NodeConfig.create().with…` chain. Available parameters: `SelfCheckPeriod` and `SessionGracePeriod`, read and attach consistency modes (`readConsistencyMode`, `attachConsistencyMode`), and rate limiter counters mode (`rateLimiterCountersMode`). Defaults match the C++ description above. Pass the resulting `NodeConfig` to `CoordinationNodeSettings`.

```
import java.time.Duration;

import tech.ydb.coordination.CoordinationClient;
import tech.ydb.coordination.description.NodeConfig;
import tech.ydb.coordination.settings.CoordinationNodeSettings;

String nodePath = client.getDatabase() + "/path/to/mynode";

NodeConfig config = NodeConfig.create()
    .withDurationsConfig(Duration.ofSeconds(1), Duration.ofSeconds(10))
    .withReadConsistencyMode(NodeConfig.ConsistencyMode.RELAXED)
    .withAttachConsistencyMode(NodeConfig.ConsistencyMode.STRICT);

CoordinationNodeSettings settings = CoordinationNodeSettings.newBuilder()
    .withNodeConfig(config)
    .build();

client.createNode(nodePath, settings).join().expectSuccess("create node failed");
```

You can also use `alterNode` (change configuration), `dropNode` (delete the node), and `describeNode` (read the current configuration).

Python

Native SDK

```
import ydb

client = driver.coordination_client
client.create_node("/path/to/mynode")
```

Native SDK (Asyncio)

```
import ydb

client = driver.coordination_client
await client.create_node("/path/to/mynode")
```

JavaScript

```
import { CoordinationClient } from "@ydbjs/coordination";

let client = new CoordinationClient(driver);
await client.createNode("/path/to/mynode", {});
```

Working with sessions

Creating a session

To start working with coordination nodes, a client must establish a session within which it will perform all operations with the coordination node.

Go

```
session, err := db.Coordination().CreateSession(ctx,
    "/path/to/mynode", // Coordination Node name in the database
)
```

C++

```
TClient client(driver);
const TSession& session = client
   .StartSession("/path/to/mynode")
   .ExtractValueSync()
   .ExtractResult();
```

When establishing a session, you can optionally pass a `TSessionSettings` structure with the following settings:

- `Description` - a text description of the session, displayed in internal interfaces and can be useful for problem diagnosis.
- `OnStateChanged` - called on significant changes during the session's life, passing the corresponding state:
  - `ATTACHED` - the session is connected and operating in normal mode.
  - `DETACHED` - the session temporarily lost connection with the service but can still be restored.
  - `EXPIRED` - the session lost connection with the service and cannot be restored.
- `OnStopped` - called when the session stops attempting to restore the connection with the service, which can be useful for establishing a new connection.
- `Timeout` - the maximum timeout during which the session can be restored after losing connection with the service.

Java

A session (see CoordinationSession) is created with `createSession`; call `connect()` to establish the bidirectional gRPC stream with the node (asynchronous, returns `CompletableFuture<Status>`). Retry behavior and connect timeout are configured in CoordinationSessionSettings (`withConnectTimeout`, `withRetryPolicy`, `withExecutor`).

```
import tech.ydb.coordination.CoordinationSession;
import tech.ydb.coordination.settings.CoordinationSessionSettings;

CoordinationSession session = client.createSession(
    "/path/to/mynode",
    CoordinationSessionSettings.newBuilder().build()
);

session.connect().join().expectSuccess("connect failed");
```

Typical flow: after a successful `connect()`, run semaphore operations for your scenario (locking, leadership, and so on), then close the session. Using try-with-resources is convenient so that `close()` stops the stream to the node when you are done.

Python

Native SDK

```
import ydb

client = driver.coordination_client
with client.session("/path/to/mynode") as session:
    # work with the session
    pass
```

Native SDK (Asyncio)

```
import ydb

client = driver.coordination_client
async with client.session("/path/to/mynode") as session:
    # work with the session
    pass
```

JavaScript

```
import { CoordinationClient } from "@ydbjs/coordination";

let client = new CoordinationClient(driver);
await using session = await client.createSession("/path/to/mynode", {}, signal);
```

Session control

It's important for the client application to monitor the session state, as it can only rely on the state of captured semaphores while the session is alive. When the session ends by client or server initiative, the client can no longer assume that other clients in the cluster haven't captured its semaphores and changed their state.

Go

In Go SDK, the session context `session.Context()` is used to track such situations, which terminates along with the session. The SDK can handle transport-level errors on its own and re-establish connection with the service, trying to restore the session if still possible. Thus, the client only needs to monitor the session context to react timely to its loss.

C++

In the C++ SDK, an active session continuously maintains and automatically re-establishes the connection with the YDB cluster in the background.

Python

In the Python SDK, the session automatically restores the connection to the YDB cluster after failures. Use a context manager (`with` or `async with`) to ensure the session is closed when leaving the block. When working with semaphores through a context manager (`with session.semaphore(name)` or `async with session.semaphore(name)`), the semaphore is released automatically when leaving the block, and the session is closed when the context exits.

Java

Call `close()` when your scenario is finished; this explicitly releases the connection to the node. Until the session is closed, the SDK retries the connection on network failures according to `CoordinationSessionSettings` . Hold a semaphore only while solving your business task and release it with `SemaphoreLease.release()` when the resource is no longer needed.

JavaScript

In the JavaScript SDK, you can use `session.signal` to monitor session lifetime: it is aborted when the session is closed or expires. The SDK handles transport-level errors and reconnects to the service, attempting to restore the session when possible. This means the client only needs to watch the session signal and avoid any operations once the session is closed or expired.

For long-running applications, the JavaScript SDK provides a recommended pattern to automatically obtain a new session when the previous one is lost: `for await (session of client.openSession()) { session.signal }`

Working with semaphores

Creating a semaphore

When creating a semaphore, you can specify its limit. The limit determines the maximum value to which it can be increased. Calls attempting to increase the semaphore value above this limit will wait until their increase requests can be fulfilled without exceeding the semaphore's limit.

Go

```
err := session.CreateSemaphore(ctx,
    "my-semaphore", // semaphore name
    10              // semaphore limit
)
```

C++

```
session
    .CreateSemaphore(
        "my-semaphore",  // semaphore name
        10               // semaphore limit
    )
    .ExtractValueSync()
    .ExtractResult();
```

You can also pass a string that will be stored with the semaphore and returned when it's captured:

```
session
    .CreateSemaphore(
        "my-semaphore",  // semaphore name
        10,              // semaphore limit
        "my-data"        // semaphore data
    )
    .ExtractValueSync()
    .ExtractResult();
```

Python

In the Python SDK, a semaphore is created implicitly on the first `acquire()` call in `session.semaphore(name, limit)`. The limit is set when the semaphore object is created.

Native SDK

```
import ydb

client = driver.coordination_client
with client.session("/path/to/mynode") as session:
    # semaphore is created on first acquire() with limit 10
    semaphore = session.semaphore("my-semaphore", 10)
```

Native SDK (Asyncio)

```
import ydb

client = driver.coordination_client
async with client.session("/path/to/mynode") as session:
    # semaphore is created on first acquire() with limit 10
    semaphore = session.semaphore("my-semaphore", 10)
```

JavaScript

```
const sem = session.semaphore("connections");
await sem.create({
  limit: 10,
  data: new Uint8Array(),
});
```

Java

Create a semaphore explicitly with `createSemaphore` on a connected session. You can pass custom binary data stored with the semaphore (`byte[] data`); the overload without `data` is equivalent to passing `null` . If a semaphore with that name already exists, the operation completes with an “already exists” status.

```
session.createSemaphore("my-semaphore", 10, new byte[] {0x00, 0x12})
    .join()
    .expectSuccess("create semaphore failed");
```

Acquiring a semaphore

To acquire a semaphore, the client must call the `AcquireSemaphore` method and wait for a special `Lease` object. This object represents confirmation that the semaphore value was successfully increased and can be considered as such until explicit release of such semaphore or termination of the session in which such confirmation was received.

Go

```
lease, err := session.AcquireSemaphore(ctx,
    "my-semaphore",  // semaphore name
    5,               // value to increase semaphore by
)
```

Similar to the session, the `Lease` object also has a context that terminates at one of these moments.

To cancel waiting for semaphore acquisition, it's sufficient to cancel the passed context `ctx` .

C++

```
session
    .AcquireSemaphore(
        "my-semaphore",                      // semaphore name
        TAcquireSemaphoreSettings().Count(5)  // value to increase semaphore by
    )
    .ExtractValueSync()
    .ExtractResult();
```

When acquiring, you can optionally pass a `TAcquireSemaphoreSettings` structure with the following settings:

- `Count` - value by which the semaphore is increased upon acquisition.
- `Data` - additional data that can be put into the semaphore.
- `OnAccepted` - called when the operation is queued. For example, if the semaphore couldn't be acquired immediately.
  - Won't be called if the semaphore is acquired immediately.
  - It's important to consider that the call can happen in parallel with the `TFuture` result.
- `Timeout` - maximum time during which the operation can stay in the queue on the server.
  - Operation will return `false` if the semaphore couldn't be acquired within `Timeout` after being added to the queue.
  - With `Timeout` set to 0, the operation works like `TryAcquire`, i.e., the semaphore will either be acquired atomically and the operation will return `true`, or the operation will return `false` without using queues.
- `Ephemeral` - if `true`, then the name is an ephemeral semaphore. Such semaphores are automatically created at first `Acquire` and automatically deleted with the last `Release`.
- `Shared()` - alias for setting `Count = 1`, acquiring semaphore in shared mode.
- `Exclusive()` - alias for setting `Count = max`, acquiring semaphore in exclusive mode. (For semaphores created with limit `Max<ui64>()`.)

Python

Native SDK

```
import ydb

client = driver.coordination_client
with client.session("/path/to/mynode") as session:
    semaphore = session.semaphore("my-semaphore", 10)
    with semaphore:
        # semaphore acquired for 1 unit (default)
        pass
    # or manually:
    semaphore = session.semaphore("my-semaphore", 10)
    semaphore.acquire(count=5)
    # work with the resource
    semaphore.release()
```

Native SDK (Asyncio)

```
import ydb

client = driver.coordination_client
async with client.session("/path/to/mynode") as session:
    semaphore = session.semaphore("my-semaphore", 10)
    async with semaphore:
        # semaphore acquired for 1 unit (default)
        pass
    # or manually:
    semaphore = session.semaphore("my-semaphore", 10)
    await semaphore.acquire(count=5)
    # work with the resource
    await semaphore.release()
```

JavaScript

```
{
  await using lease = await sem.acquire({ count: 1, data: new Uint8Array() });
  await doWork(lease.signal);
} // lease.release() called automatically
```

Java

Acquisition is done via `acquireSemaphore` with the semaphore name, token `count`, optional operation data, and queue wait timeout as java.time.Duration. The method returns `CompletableFuture<Result<SemaphoreLease>>` (see Result and SemaphoreLease). If no semaphore exists with the given name, the operation fails with an exception (see the method javadoc).

```
import java.time.Duration;

import tech.ydb.coordination.SemaphoreLease;
import tech.ydb.core.Result;

Result<SemaphoreLease> result = session
    .acquireSemaphore("my-semaphore", 5, Duration.ofSeconds(30))
    .join();

result.getStatus().expectSuccess("cannot acquire semaphore");
SemaphoreLease lease = result.getValue();
```

For **ephemeral** semaphores, use `acquireEphemeralSemaphore` (the `exclusive` flag sets the acquisition mode); such semaphores are created on first acquire and removed after the last release.

The API documentation states that a session can hold **only one** semaphore at a time; repeated calls for the same name **replace** the previous operation (for example, to reduce `count` or change the timeout).

The taken value of an acquired semaphore can be decreased (but not increased) by calling the `AcquireSemaphore` method again with a smaller value.

Updating semaphore data

Using the `UpdateSemaphore` method, you can update (replace) the semaphore data that was attached during its creation.

Go

```
err := session.UpdateSemaphore(
    "my-semaphore",                                  // semaphore name
    options.WithUpdateData([]byte("updated-data")),  // new semaphore data
)
```

C++

```
session
    .UpdateSemaphore(
        "my-semaphore",  // semaphore name
        "updated-data"   // new semaphore data
    )
    .ExtractValueSync()
    .ExtractResult();
```

Python

Native SDK

```
import ydb

client = driver.coordination_client
with client.session("/path/to/mynode") as session:
    semaphore = session.semaphore("my-semaphore", 10)
    semaphore.update(b"updated-data")
```

Native SDK (Asyncio)

```
import ydb

client = driver.coordination_client
async with client.session("/path/to/mynode") as session:
    semaphore = session.semaphore("my-semaphore", 10)
    await semaphore.update(b"updated-data")
```

Java

```
session.updateSemaphore("my-semaphore", "updated-data".getBytes(java.nio.charset.StandardCharsets.UTF_8))
    .join()
    .expectSuccess("update semaphore failed");
```

JavaScript

```
const sem = session.semaphore("connections");
await sem.update({
  limit: 5,
  data: new Uint8Array(),
});
```

This call doesn't require acquiring the semaphore and doesn't lead to it. If you need only one specific client to update the data, this must be explicitly ensured, for example, by acquiring the semaphore, updating the data, and releasing the semaphore back.

Getting semaphore data

Go

```
description, err := session.DescribeSemaphore(
    "my-semaphore"                                  // semaphore name
    options.WithDescribeOwners(true), // to get list of owners
    options.WithDescribeWaiters(true), // to get list of waiters
)
```

C++

```
session
    .DescribeSemaphore(
        "my-semaphore"  // semaphore name
    )
    .ExtractValueSync()
    .ExtractResult();
```

When getting information about a semaphore, you can optionally pass a `TDescribeSemaphoreSettings` structure with the following settings:

- `OnChanged` - called once after data changes on the server (with a `bool` parameter, if `true` - the call occurred due to some changes, if `false` - it's a false call and you need to repeat `DescribeSemaphore` to restore the subscription).
- `WatchData` - call `OnChanged` when semaphore data changes.
- `WatchOwners` - call `OnChanged` when semaphore owners change.
- `IncludeOwners` - return the list of owners in the results.
- `IncludeWaiters` - return the list of waiters in the results.

The call result is a structure with the following fields:

- `Name` - semaphore name.
- `Data` - semaphore data.
- `Count` - the current value of the semaphore.
- `Limit` - the limit specified when creating the semaphore.
- `Owners` - list of semaphore owners.
- `Waiters` - list of clients waiting in the semaphore queue.
- `Ephemeral` - whether the semaphore is ephemeral.

The `Owners` and `Waiters` fields in the result contain a list of structures with the following fields:

- `OrderId` - sequence number of the acquire operation on the semaphore (can be used for identification, for example if `OrderId` changed, it means the session called `ReleaseSemaphore` and a new `AcquireSemaphore`).
- `SessionId` - identifier of the session that made this `AcquireSemaphore` call.
- `Timeout` - timeout value used in the `AcquireSemaphore` call for queued operations.
- `Count` - value requested in `AcquireSemaphore`.
- `Data` - data specified in `AcquireSemaphore`.

Python

Native SDK

```
import ydb

client = driver.coordination_client
with client.session("/path/to/mynode") as session:
    semaphore = session.semaphore("my-semaphore", 10)
    description = semaphore.describe()
    # description contains: name, data, count, limit, owners, waiters, ephemeral
```

Native SDK (Asyncio)

```
import ydb

client = driver.coordination_client
async with client.session("/path/to/mynode") as session:
    semaphore = session.semaphore("my-semaphore", 10)
    description = await semaphore.describe()
    # description contains: name, data, count, limit, owners, waiters, ephemeral
```

Java

The `describeSemaphore` method takes a semaphore name and a DescribeSemaphoreMode: data only, with owners list, with waiters list, or both.

```
import tech.ydb.coordination.description.SemaphoreDescription;
import tech.ydb.coordination.settings.DescribeSemaphoreMode;

SemaphoreDescription description = session
    .describeSemaphore("my-semaphore", DescribeSemaphoreMode.WITH_OWNERS_AND_WAITERS)
    .join()
    .getValue();
```

Owner and waiter list entries (`getOwnersList` , `getWaitersList`) expose session id, timeout, requested `count` , operation data, and `orderId` (see the nested `SemaphoreDescription.Session` type in the sources).

To subscribe to changes, use `watchSemaphore` with the same describe mode and WatchSemaphoreMode (data, owners, or both). SemaphoreWatcher holds a `SemaphoreDescription` snapshot and `getChangedFuture()` — `CompletableFuture<Result<SemaphoreChangedEvent>>` (see SemaphoreChangedEvent, fields `isDataChanged` , `isOwnersChanged`). The future completes on the next event; call `watchSemaphore` again to continue watching (see tests).

JavaScript

```
const sem = session.semaphore("connections");
await sem.describe({
  owners: true,
  waiters: true,
});
```

Releasing a semaphore

Go

To release a semaphore acquired in a session, call the `Release` method on the `Lease` object.

```
err := lease.Release()
```

C++

```
session
    .ReleaseSemaphore(
        "my-semaphore"  // semaphore name
    )
    .ExtractValueSync()
    .ExtractResult();
```

Python

In the Python SDK, a semaphore is released with the `release()` method on the semaphore object. When using a context manager (`with` or `async with`), release happens automatically when leaving the block.

Native SDK

```
import ydb

client = driver.coordination_client
with client.session("/path/to/mynode") as session:
    semaphore = session.semaphore("my-semaphore", 10)
    semaphore.acquire(count=5)
    # work with the resource
    semaphore.release()
```

Native SDK (Asyncio)

```
import ydb

client = driver.coordination_client
async with client.session("/path/to/mynode") as session:
    semaphore = session.semaphore("my-semaphore", 10)
    await semaphore.acquire(count=5)
    # work with the resource
    await semaphore.release()
```

Java

Release via SemaphoreLease.release() (asynchronous, `CompletableFuture<Status>`).

```
lease.release().join().expectSuccess("release failed");
```

JavaScript

To release a semaphore acquired within a session, call `release()` on the `Lease` object. If you use `await using` , the lease is released automatically when leaving the scope.

```
await lease.release();
```

Important implementation details

The `AcquireSemaphore` and `ReleaseSemaphore` operations are idempotent. When `AcquireSemaphore` is invoked on a semaphore, subsequent calls to `AcquireSemaphore` only adjust the acquisition parameters. For instance, if `AcquireSemaphore` is called with `count=10` , the operation might be queued. You can call `AcquireSemaphore` again with `count=9` before or after successful acquisition, reducing the number of acquired units. The new operation replaces the old one, which will complete with an `ABORTED` code if it hasn't completed successfully yet. The queue position remains unchanged despite replacing one `AcquireSemaphore` operation with another.

Both `AcquireSemaphore` and `ReleaseSemaphore` operations return a `bool` indicating whether the semaphore state was altered. For example, `AcquireSemaphore` might return `false` if the semaphore couldn't be acquired within the `Timeout` period because it was acquired by another entity. Similarly, `ReleaseSemaphore` might return `false` if the semaphore isn't acquired within the current session.

A queued `AcquireSemaphore` operation can be prematurely terminated by calling `ReleaseSemaphore`. Regardless of how many `AcquireSemaphore` calls are made for a specific semaphore within one session, a single `ReleaseSemaphore` call releases it. Thus, `AcquireSemaphore` and `ReleaseSemaphore` operations cannot function as `Acquire` / `Release` on a recursive mutex.

The `DescribeSemaphore` operation with `WatchData` or `WatchOwners` flags set establishes a subscription for semaphore changes. Any previous subscription to the same semaphore within the session is canceled, triggering `OnChanged(false)`. It is advisable to disregard `OnChanged` from earlier `DescribeSemaphore` calls if a new replacing call is made, for instance, by tracking a current call ID.

The `OnChanged(false)` call might occur not only due to cancellation by a new `DescribeSemaphore` but also for various reasons, such as temporary connection loss between the gRPC client and server, temporary connection loss between the gRPC server and the current service leader, or service leader changes. This happens at the slightest suspicion that a notification might have been lost. To restore the subscription, client code must issue a new `DescribeSemaphore` call, properly managing the situation where the result of the new call might differ (for example, if the notification was indeed lost).

Examples

- Distributed lock
- Leader election
- Service discovery
- Configuration publication

Handling errors

You need to handle errors properly when using the YDB SDK.

Errors can be divided into three categories:

- **Temporary failures** (retryable). Such errors include a short-term loss of network connectivity, temporary unavailability, overload of a YDB subsystem, or a failure of YDB to respond to a query within the set timeout. If one of these errors occurs, retrying the failed query is likely to be successful after some time.
- **Errors that cannot be fixed with a retry** (non-retryable). Such errors are caused by incorrectly written queries, YDB internal errors, or queries that mismatch the data schema. Retrying such queries will not resolve the issue. This situation requires developer attention.
- **Errors that can presumably be fixed with a retry after the client application response** (conditionally retryable). Such errors include no response within the set timeout or an authentication request. Only idempotent operations can be fixed with a retry.

Handling retryable errors

The YDB SDK provides a built-in mechanism for handling temporary failures. By default, the SDK uses the recommended retry policy, which can be changed to meet the requirements of the client application. YDB returns status codes that let you determine whether a retry is appropriate and which interval to select.

You should retry an operation only if an error refers to a temporary failure. Do not retry invalid operations, such as inserting a row with an existing primary key value into a table or inserting data that mismatches the table schema.

It is extremely important to optimize the number of retries and the interval between them. An excessive number of retries and too short an interval between them result in excessive load. An insufficient number of retries prevents the operation from completing.

The built-in retry mechanisms in YDB SDKs use the following backoff strategies depending on the returned status code:

- **Instant retry** – Retries are made immediately.
- **Fast exponential backoff** – The initial interval is several milliseconds. For each subsequent attempt, the interval increases exponentially.
- **Slow exponential backoff** – The initial interval is several seconds. For each subsequent attempt, the interval increases exponentially.

When selecting an interval manually, the following strategies are usually used:

- **Exponential backoff** – For each subsequent attempt, the interval increases exponentially.
- **Intervals in increments** – For each subsequent attempt, the interval increases in certain increments.
- **Constant intervals** – Retries are made at the same intervals.
- **Instant retry** – Retries are made immediately.
- **Random selection** – Retries are made after a randomly selected time interval.

When selecting an interval and the number of retries, consider the YDB status codes.

Do not use endless retries, as this may result in excessive load.

Do not repeat instant retries more than once.

For code samples, see Retrying.

Status codes

When an error occurs, the YDB SDK returns an error object that includes status codes. The returned status code may come from the YDB server, gRPC transport, or the SDK itself.

Status codes within the range of 400000-400999 are YDB server codes that are identical for all YDB SDKs. Refer to Status codes from the YDB server.

Status codes within the range of 401000-401999 are SDK-specific. For more information about SDK-specific codes, refer to the corresponding SDK documentation.

For more information about gRPC status codes, see the gRPC documentation.

Logging errors

When using the SDK, we recommend logging all errors and exceptions:

- Log the number of retries made. An increase in the number of regular retries often indicates issues.
- Log all errors, including their types, termination codes, and causes.
- Log the total operation execution time, including operations that terminate after retries.

Status codes from the YDB server

Code	Status	Retryability	Backoff strategy	Recreate session
400000	SUCCESS	–	–	–
400010	BAD_REQUEST	non-retryable[2]	–	no
400020	UNAUTHORIZED	non-retryable[2]	–	no
400030	INTERNAL_ERROR	non-retryable[2]	–	no
400040	ABORTED	retryable[3]	fast[4]	no
400050	UNAVAILABLE	retryable[3]	fast[4]	no
400060	OVERLOADED	retryable[3]	slow[5]	no
400070	SCHEME_ERROR	non-retryable[2]	–	no
400080	GENERIC_ERROR	non-retryable[2]	–	no
400090	TIMEOUT	non-retryable[2]	–	no
400100	BAD_SESSION	retryable[3]	instant[6]	yes
400120	PRECONDITION_FAILED	non-retryable[2]	–	no
400130	ALREADY_EXISTS	non-retryable[2]	–	no
400140	NOT_FOUND	non-retryable[2]	–	no
400150	SESSION_EXPIRED	retryable[3]	instant[6]	yes
400160	CANCELLED	non-retryable[2]	–	no
400170	UNDETERMINED	conditionally-retryable[7]	fast[4]	no
400180	UNSUPPORTED	non-retryable[2]	–	no
400190	SESSION_BUSY	retryable[3]	fast[4]	yes
400200	EXTERNAL_ERROR	non-retryable[2]	–	no

400000: SUCCESS

The query was processed successfully.

No response is required. Continue application execution.

400010: BAD_REQUEST Non-retryable

Invalid query syntax or missing required fields.

Correct the query.

400020: UNAUTHORIZED Non-retryable

Access to the requested schema object (for example, a table or directory) is denied.

Request access from its owner.

400030: INTERNAL_ERROR Non-retryable

An unknown internal error occurred.

File a GitHub issue or contact YDB technical support.

400040: ABORTED Retryable | Fast Backoff

The operation was aborted. Possible reasons might include lock invalidation with `TRANSACTION_LOCKS_INVALIDATED` in detailed error messages.

Retry the entire transaction.

400050: UNAVAILABLE Retryable | Fast Backoff

A part of the system is not available.

Retry the last action (query).

400060: OVERLOADED Retryable | Slow Backoff

A part of the system is overloaded.

Retry the last action (query) and reduce the query rate.

400070: SCHEME_ERROR Non-retryable

The query does not match the schema.

Correct the query or schema.

400080: GENERIC_ERROR Non-retryable

An unclassified error occurred, possibly related to the query.

See the detailed error message. If necessary, file a GitHub issue or contact YDB technical support.

400090: TIMEOUT Conditionally retryable | Instant

The query timeout expired.

If the query is idempotent, retry it.

400100: BAD_SESSION Retryable | Instant

This session is no longer available.

Create a new session.

400120: PRECONDITION_FAILED Non-retryable

The query cannot be executed in the current state. For example, inserting data into a table with an existing key.

Correct the state or query, then retry.

400130: ALREADY_EXISTS Non-retryable

The database object being created already exists in the YDB cluster.

The response depends on the application logic.

400140: NOT_FOUND Non-retryable

The database object was not found in the YDB database.

The response depends on the application logic.

400150: SESSION_EXPIRED Conditionally retryable | Instant

The session has already expired.

Create a new session.

400160: CANCELLED Non-retryable

The request was canceled on the server. For example, a user canceled a long-running query in the YDB UI, the query included the cancel_after timeout option, or the session was closed while the query was running.

If the session was closed, create a new session before sending another request. If the query took too long to complete, try optimizing it. If you used the `cancel_after` timeout option, increase the timeout value.

400170: UNDETERMINED Conditionally retryable | Fast Backoff

An unknown transaction status. The query ended with a failure, making it impossible to determine the transaction status. Queries that terminate with this status are subject to transaction integrity and atomicity guarantees. That is, either all changes are registered, or the entire transaction is canceled.

For idempotent transactions, retry the entire transaction after a short delay. Otherwise, the response depends on the application logic.

400180: UNSUPPORTED Non-retryable

The query is not supported by YDB either because support for such queries is not yet implemented or is not enabled in the YDB configuration.

Correct the query or enable support for such queries in YDB.

400190: SESSION_BUSY Retryable | Fast Backoff

The session is busy.

Create a new session.

400200: EXTERNAL_ERROR Non-retryable

An error occurred in an external system, for example, when processing a federated query or importing data from an external data source.

See the detailed error message. If necessary, file a GitHub issue or contact YDB technical support.

Questions and answers: Errors

---

[2] **Errors that cannot be fixed with a retry** (non-retryable). Such errors are caused by incorrectly written queries, YDB internal errors, or queries that mismatch the data schema. Retrying such queries will not resolve the issue. This situation requires developer attention.

[3] **Temporary failures** (retryable). Such errors include a short-term loss of network connectivity, temporary unavailability, overload of a YDB subsystem, or a failure of YDB to respond to a query within the set timeout. If one of these errors occurs, retrying the failed query is likely to be successful after some time.

[4] **Fast exponential backoff** is one of the backoff strategies used in YDB SDK when retrying queries that return an error.

The initial interval for this strategy is several **milliseconds**. For each subsequent attempt, the interval increases exponentially.

For more information, see Handling retryable errors.

[5] **Slow exponential backoff** is one of the backoff strategies used by YDB SDK when retrying queries that return an error.

The initial interval for this strategy is several **seconds**. For each subsequent attempt, the interval increases exponentially.

For more information, see Handling retryable errors.

[6] **Instant retry** is one of the backoff strategies used in YDB SDK when retrying queries that return an error.

This strategy retries queries immediately after receiving an error.

For more information, see Handling retryable errors.

[7] **Errors that can presumably be fixed with a retry after the client application response** (conditionally retryable). Such errors include no response within the set timeout or an authentication request. Only idempotent operations can be fixed with a retry.

gRPC status codes

YDB provides the gRPC API, which you can use to manage your database resources and data. The following table describes the gRPC status codes:

Code	Status	Retryability	Backoff strategy	Recreate session
0	OK	–	–	–
1	CANCELLED	conditionally-retryable[8]	fast[9]	yes
2	UNKNOWN	non-retryable[10]	–	yes
3	INVALID_ARGUMENT	non-retryable[10]	–	yes
4	DEADLINE_EXCEEDED	conditionally-retryable[8]	fast[9]	yes
5	NOT_FOUND	non-retryable[10]	–	yes
6	ALREADY_EXISTS	non-retryable[10]	–	yes
7	PERMISSION_DENIED	non-retryable[10]	–	yes
8	RESOURCE_EXHAUSTED	retryable[11]	slow[12]	no
9	FAILED_PRECONDITION	non-retryable[10]	–	yes
10	ABORTED	retryable[11]	instant[13]	yes
11	OUT_OF_RANGE	non-retryable[10]	–	no
12	UNIMPLEMENTED	non-retryable[10]	–	yes
13	INTERNAL	conditionally-retryable[8]	fast[9]	yes
14	UNAVAILABLE	conditionally-retryable[8]	fast[9]	yes
15	DATA_LOSS	non-retryable[10]	–	yes
16	UNAUTHENTICATED	non-retryable[10]	–	yes

0: OK

Not an error; returned on success.

1: CANCELLED Conditionally retryable | Fast Backoff

The operation was cancelled, typically by the caller.

2: UNKNOWN Non-retryable

Unknown error. For example, this error may be returned when a `Status` value received from another address space belongs to an error space that is not known in this address space. Errors raised by APIs that do not return enough error information may also be converted to this error.

3: INVALID_ARGUMENT Non-retryable

The client specified an invalid argument. Unlike `FAILED_PRECONDITION`, `INVALID_ARGUMENT` indicates arguments that are problematic regardless of the system state (e.g., a malformed file name).

4: DEADLINE_EXCEEDED Conditionally retryable | Fast Backoff

The query was not processed within the specified client timeout, or a network issue occurred.

Check the specified timeout, network access, endpoint, and other network settings. Reduce the query rate and optimize queries.

5: NOT_FOUND Non-retryable

A requested scheme object (for example, a table or directory) was not found.

6: ALREADY_EXISTS Non-retryable

The scheme object that a client attempted to create (e.g., file or directory) already exists.

7: PERMISSION_DENIED Non-retryable

The caller does not have permission to execute the specified operation.

8: RESOURCE_EXHAUSTED Retryable | Slow Backoff

There are not enough resources available to fulfill the query.

Reduce the query rate and check client balancing.

9: FAILED_PRECONDITION Non-retryable

The query cannot be executed in the current state (for example, inserting data into a table with an existing key).

Fix the state or query, then retry.

10: ABORTED Retryable | Instant

The operation was aborted, typically due to a concurrency issue, such as a transaction abort.

11: OUT_OF_RANGE Non-retryable

The operation was attempted past the valid range. Unlike `INVALID_ARGUMENT`, this error indicates a problem that may be fixed if the system state changes.

12: UNIMPLEMENTED Non-retryable

The operation is not implemented, supported, or enabled in this service.

13: INTERNAL Conditionally retryable | Fast Backoff

Internal errors. This means that some invariants expected by the underlying system have been broken. This error code is reserved for significant problems.

14: UNAVAILABLE Conditionally retryable | Fast Backoff

The service is currently unavailable. This is most likely a transient condition that can be corrected by retrying with a backoff. Note that it is not always safe to retry non-idempotent operations.

15: DATA_LOSS Non-retryable

Unrecoverable data loss or corruption.

16: UNAUTHENTICATED Non-retryable

The request did not have valid authentication credentials.

Retry the request with valid authentication credentials.

---

[8] **Errors that can presumably be fixed with a retry after the client application response** (conditionally retryable). Such errors include no response within the set timeout or an authentication request. Only idempotent operations can be fixed with a retry.

[9] **Fast exponential backoff** is one of the backoff strategies used in YDB SDK when retrying queries that return an error.

The initial interval for this strategy is several **milliseconds**. For each subsequent attempt, the interval increases exponentially.

For more information, see Handling retryable errors.

[10] **Errors that cannot be fixed with a retry** (non-retryable). Such errors are caused by incorrectly written queries, YDB internal errors, or queries that mismatch the data schema. Retrying such queries will not resolve the issue. This situation requires developer attention.

[11] **Temporary failures** (retryable). Such errors include a short-term loss of network connectivity, temporary unavailability, overload of a YDB subsystem, or a failure of YDB to respond to a query within the set timeout. If one of these errors occurs, retrying the failed query is likely to be successful after some time.

[12] **Slow exponential backoff** is one of the backoff strategies used by YDB SDK when retrying queries that return an error.

The initial interval for this strategy is several **seconds**. For each subsequent attempt, the interval increases exponentially.

For more information, see Handling retryable errors.

[13] **Instant retry** is one of the backoff strategies used in YDB SDK when retrying queries that return an error.

This strategy retries queries immediately after receiving an error.

For more information, see Handling retryable errors.

gRPC API overview

YDB provides the gRPC API, which you can use to manage your DB resources and data. API methods and data structures are described using Protocol Buffers (proto 3). For more information, see .proto specifications with comments. Also YDB uses special gRPC metadata headers.

The following services are available:

- Health Check API.

gRPC metadata headers

YDB uses the following gRPC metadata headers:

- gRPC headers which a client sends to YDB:
  - `x-ydb-database` - database
  - `x-ydb-auth-ticket` - auth token from a credentials provider
  - `x-ydb-sdk-build-info` - YDB SDK build info
  - `x-ydb-trace-id` - user-defined request ID. If not defined by client YDB SDK generates automatically using UUID format
  - `x-ydb-application-name` - optional user-defined application name
  - `x-ydb-client-capabilities` - supported client SDK capabilities (`session-balancer` and other)
  - `x-ydb-client-pid` - client application process ID
  - `traceparent` - OpenTelemetry trace ID (specification)
- gRPC headers which YDB sends to client with responses:
  - `x-ydb-server-hints` - notifications from YDB (such as `session-close` and other)
  - `x-ydb-consumed-units` - consumed units on the current request

Health Check API

YDB has a built-in self-diagnostic system, which can be used to get a brief report on the database status and information about existing issues.

To initiate the check, call the `SelfCheck` method from `NYdb::NMonitoring` namespace in the SDK. You must also pass the name of the checked DB as usual.

C++

App code snippet for creating a client:

```
auto client = NYdb::NMonitoring::TMonitoringClient(driver);
```

Calling `SelfCheck` method:

```
auto settings = TSelfCheckSettings();
settings.ReturnVerboseStatus(true);
auto result = client.SelfCheck(settings).GetValueSync();
```

Go

This functionality is not currently supported.

Java

This functionality is not currently supported.

Python

This functionality is not currently supported.

JavaScript

This functionality is not currently supported in the JavaScript SDK. You can create a monitoring client and call health-check APIs yourself:

```
const monitoring = driver.createClient(MonitoringServiceDefinition);
await monitoring.selfCheck();
```

Rust

This functionality is not currently supported.

Track progress or vote for Rust SDK support: ydb-rs-sdk#494

Call parameters

`SelfCheck` method provides information in the form of a set of issues which could look like this:

```
{
  "id": "RED-27c3-70fb",
  "status": "RED",
  "message": "Database has multiple issues",
  "location": {
    "database": {
      "name": "/slice"
    }
  },
  "reason": [
    "RED-27c3-4e47",
    "RED-27c3-53b5",
    "YELLOW-27c3-5321"
  ],
  "type": "DATABASE",
  "level": 1
}
```

This is a short messages each about a single issue. All parameters will affect the amount of information the service returns for the specified database.

The complete list of extra parameters is presented below:

C++

```
struct TSelfCheckSettings : public TOperationRequestSettings<TSelfCheckSettings>{
    FLUENT_SETTING_OPTIONAL(bool, ReturnVerboseStatus);
    FLUENT_SETTING_OPTIONAL(EStatusFlag, MinimumStatus);
    FLUENT_SETTING_OPTIONAL(ui32, MaximumLevel);
};
```

Go

This functionality is not currently supported.

Java

This functionality is not currently supported.

Python

This functionality is not currently supported.

JavaScript

This section is under development.

Rust

This functionality is not currently supported.

Track progress or vote for Rust SDK support: ydb-rs-sdk#494

Parameter	Type	Description
`ReturnVerboseStatus`	`bool`	If `ReturnVerboseStatus` is specified, the response will also include a summary of the overall health of the database in the `database_status` field (Example). Default is false.
`MinimumStatus`	[EStatusFlag] (#issue-status)	Each issue has a `status` field. If `minimum_status` is specified, issues with a higher `status` will be discarded. By default, all issues will be listed.
`MaximumLevel`	`int32`	Each issue has a `level` field. If `maximum_level` is specified, issues with deeper levels will be discarded. By default, all issues will be listed.

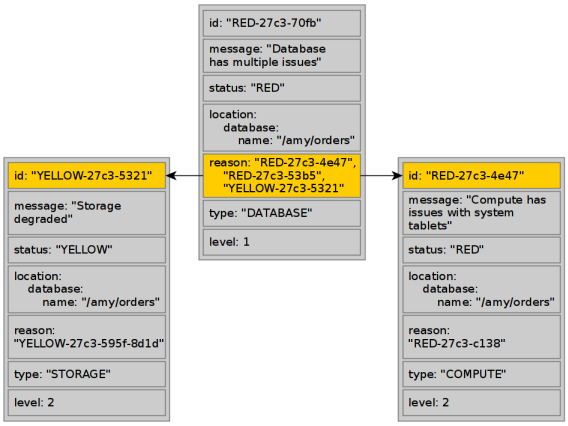
Response structure

For the full response structure, see the ydb_monitoring.proto file in the YDB Git repository.
Calling the `SelfCheck` method will return the following message:

```
message SelfCheckResult {
    SelfCheck.Result self_check_result = 1;
    repeated IssueLog issue_log = 2;
    repeated DatabaseStatus database_status = 3;
    LocationNode location = 4;
}
```

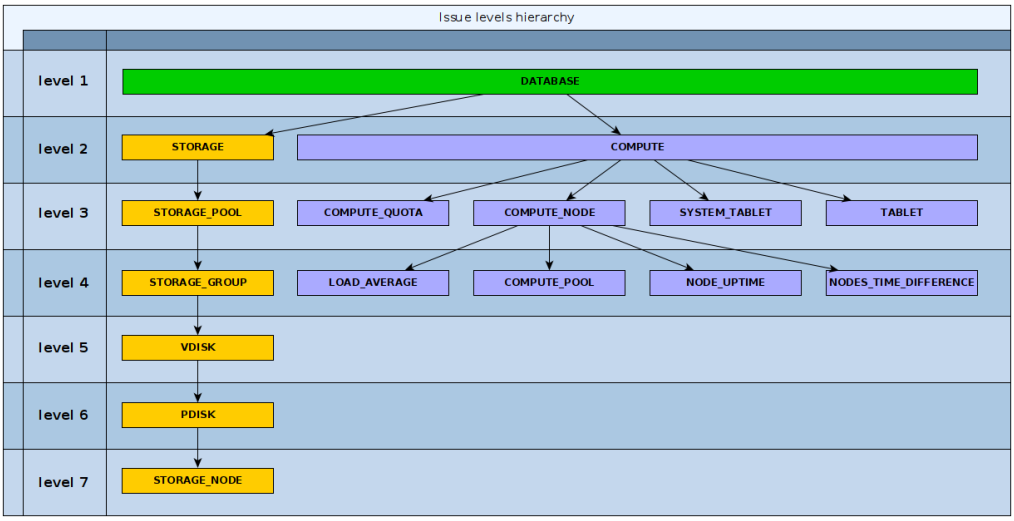
The shortest `HealthCheck` response looks like this . It is returned if there is nothing wrong with the database.

If any issues are detected, the `issue_log` field will contain descriptions of the issues with the following structure:



```
message IssueLog {
    string id = 1;
    StatusFlag.Status status = 2;
    string message = 3;
    Location location = 4;
    repeated string reason = 5;
    string type = 6;
    uint32 level = 7;
}
```

Description of fields in the response



Field	Description
`self_check_result`	enum field which contains the database check result
`issue_log`	A list of issues; each entry describes a problem at a particular level of the system.
`issue_log.id`	A unique issue ID within this response.
`issue_log.status`	enum field which contains the issue status
`issue_log.message`	Text that describes the issue.
`issue_log.location`	Location of the issue. This can be a physical location or an execution context.
`issue_log.reason`	This is a set of elements, each of which describes an issue in the system at a certain level.
`issue_log.type`	Issue category (by subsystem). Each type is at a certain level and interconnected with others through a rigid hierarchy (as shown in the picture above).
`issue_log.level`	Issue nesting depth.
`database_status`	If the settings include `ReturnVerboseStatus` parameter, the `database_status` field will be populated. This field offers a comprehensive summary of the overall health of the database. It is designed to provide a quick overview of the database's condition, helping to assess its health and identify any major issues at a high level. Example. For the full response structure, see the ydb_monitoring.proto file in the YDB Git repository.
`location`	Contains information about the host, where the `HealthCheck` service was called

Issues hierarchy

Issues can be arranged hierarchically using the `id` and `reason` fields, which help visualize how issues in different modules affect the overall system state. All issues are arranged in a hierarchy where higher levels can depend on nested levels:

Each issue has a nesting `level`. The higher the `level`, the deeper the issue is within the hierarchy. Issues with the same `type` always have the same `level`, and they can be represented hierarchically.

Database check result

The most general status of the database `self_check_result` can have the following values:

Value	Description
`GOOD`	No issues were detected.
`DEGRADED`	Degradation of at least one of the database systems was detected, but the database is still functioning (for example, allowable disk loss).
`MAINTENANCE_REQUIRED`	Significant degradation was detected, there is a risk of database unavailability, and human intervention is required.
`EMERGENCY`	A serious problem was detected in the database, with complete or partial unavailability.

Issue status

The status (severity) of the current issue `issue_log.status`:

Value	Description
`GREY`	Unable to determine the status (an issue with the self-diagnostic subsystem).
`GREEN`	No issues detected.
`BLUE`	Temporary minor degradation that does not affect database availability; the system is expected to return to `GREEN`.
`YELLOW`	A minor issue with no risks to availability. It is recommended to continue monitoring the issue.
`ORANGE`	A serious issue, a step away from losing availability. Maintenance may be required.
`RED`	A component is faulty or unavailable.

Possible issues

DATABASE

Database has multiple issues, Database has compute issues, Database has storage issues

Description: These issues depend solely on the underlying `COMPUTE` and `STORAGE` layers. This represents the most general status of a database.

STORAGE

There are no storage pools

Description: Information about storage pools is unavailable. Most likely, the storage pools are not configured.

Storage degraded, Storage has no redundancy, Storage failed

Description: These issues depend solely on the underlying `STORAGE_POOLS` layer.

System tablet BSC didn't provide information

Description: Storage diagnostics will be generated using an alternative method.

Storage usage over 75%, Storage usage over 85%, Storage usage over 90%

Description: Some data needs to be removed, or the database needs to be reconfigured with additional disk space.

STORAGE_POOL

Pool degraded, Pool has no redundancy, Pool failed

Description: These issues depend solely on the underlying `STORAGE_GROUP` layer.

STORAGE_GROUP

Group has no vslots

Description: This situation is not expected; it is an internal issue.

Group layout is incorrect

Description: The storage group was configured incorrectly.

Actions: In the YDB UI, navigate to the database page, select the `Storage` tab, and use the known group `id` to check the configuration of nodes and disks on the nodes.

Group degraded

Description: A number of disks allowed in the group are not available.

Logic of work: `HealthCheck` checks various parameters (fault tolerance mode, number of failed disks, disk status, etc.) and sets the appropriate status for the group accordingly.

Actions: In YDB UI, navigate to the database page, select the `Storage` tab, apply the `Groups` and `Degraded` filters, and use the known group `id` to check the availability of nodes and disks on the nodes.

Group has no redundancy

Description: A storage group has lost its redundancy. Another VDisk failure could result in the loss of the group.

Logic of work: `HealthCheck` monitors various parameters (fault tolerance mode, number of failed disks, disk status, etc.) and sets the appropriate status for the group based on these parameters.

Actions: In YDB UI, navigate to the database page, select the `Storage` tab, apply the `Groups` and `Degraded` filters, and use the known group `id` to check the availability of nodes and disks on those nodes.

Group failed

Description: A storage group has lost its integrity, and data is no longer available. `HealthCheck` evaluates various parameters (fault tolerance mode, number of failed disks, disk status, etc.) and determines the appropriate status, displaying a message accordingly.

Logic of work: `HealthCheck` monitors various parameters (fault tolerance mode, number of failed disks, disk status, etc.) and sets the appropriate status for the group accordingly.

Actions: In YDB UI, navigate to the database page, select the `Storage` tab, apply the `Groups` and `Degraded` filters, and use the known group `id` to check the availability of nodes and disks on those nodes.

VDISK

System tablet BSC did not provide known status

Description: This situation is not expected; it is an internal issue.

VDisk is not available

Description: The disk is not operational.

Actions: In YDB YDB UI, navigate to the database page, select the `Storage` tab, and apply the `Groups` and `Degraded` filters. The group `id` can be found through the related `STORAGE_GROUP` issue. Hover over the relevant VDisk to identify the node with the problem and check the availability of nodes and disks on those nodes.

VDisk is being initialized

Description: The disk is in the process of initialization.

Actions: In YDB UI, navigate to the database page, select the `Storage` tab, and apply the `Groups` and `Degraded` filters. The group `id` can be found through the related `STORAGE_GROUP` issue. Hover over the relevant VDisk to identify the node with the problem and check the availability of nodes and disks on those nodes.

Replication in progress

Description: The disk is accepting queries, but not all data has been replicated.

Actions: In YDB UI, navigate to the database page, select the `Storage` tab, and apply the `Groups` and `Degraded` filters. The group `id` can be found through the related `STORAGE_GROUP` issue. Hover over the relevant VDisk to identify the node with the problem and check the availability of nodes and disks on those nodes.

VDisk have space issue

Description: These issues depend solely on the underlying `PDISK` layer.

PDISK

Unknown PDisk state

Description: `HealthCheck` the system can't parse pdisk state.

PDisk state is

Description: Indicates state of physical disk.

Actions: In YDB UI, navigate to the database page, select the `Storage` tab, set the `Nodes` and `Degraded` filters, and use the known node id and PDisk to check the availability of nodes and disks on the nodes.

Available size is less than 12%, Available size is less than 9%, Available size is less than 6%

Description: Free space on the physical disk is running out.
Actions: In YDB UI, navigate to the database page, select the `Storage` tab, set the `Nodes` and `Out of Space` filters, and use the known node and PDisk identifiers to check the available space.

PDisk is not available

Description: A physical disk is not available.

Actions: In YDB UI, navigate to the database page, select the `Storage` tab, set the `Nodes` and `Degraded` filters, and use the known node and PDisk identifiers to check the availability of nodes and disks on the nodes.

STORAGE_NODE

Storage node is not available

Description: A storage node is not available.

COMPUTE

There are no compute nodes

Description: The database has no nodes available to start the tablets. Unable to determine `COMPUTE_NODE` issues below.

Compute has issues with system tablets

Description: These issues depend solely on the underlying `SYSTEM_TABLET` layer.

Some nodes are restarting too often

Description: These issues depend solely on the underlying `NODE_UPTIME` layer.

Compute is overloaded

Description: These issues depend solely on the underlying `COMPUTE_POOL` layer.

Compute quota usage

Description: These issues depend solely on the underlying `COMPUTE_QUOTA` layer.

Compute has issues with tablets

Description: These issues depend solely on the underlying `TABLET` layer.

COMPUTE_QUOTA

Paths quota usage is over than 90%, Paths quota usage is over than 99%, Paths quota exhausted, Shards quota usage is over than 90%, Shards quota usage is over than 99%, Shards quota exhausted

Description: Quotas are exhausted.

Actions: Check the number of objects (tables, topics) in the database and delete any unnecessary ones.

SYSTEM_TABLET

System tablet is unresponsive, System tablet response time over 1000ms, System tablet response time over 5000ms

Description: The system tablet is either not responding or takes too long to respond.

Actions: In YDB UI, navigate to the `Storage` tab and apply the `Nodes` filter. Check the `Uptime` and the nodes' statuses. If the `Uptime` is short, review the logs to determine the reasons for the node restarts.

TABLET

Tablets are restarting too often

Description: Tablets are restarting too frequently.

Actions: In YDB UI, navigate to the `Nodes` tab. Check the `Uptime` and the nodes' statuses. If the `Uptime` is short, review the logs to determine the reasons for the node restarts.

Tablets/Followers are dead

Description: Tablets are not running (likely cannot be started).

Actions: In YDB UI, navigate to the `Nodes` tab. Check the `Uptime` and the nodes' statuses. If the `Uptime` is short, review the logs to determine the reasons for the node restarts.

LOAD_AVERAGE

LoadAverage above 100%

Description: A physical host is overloaded, meaning the system is operating at or beyond its capacity, potentially due to a high number of processes waiting for I/O operations. For more information on load, see Load (computing).

Logic of work:

- Load Information:
  - Source: `/proc/loadavg`
  - The first number of the three represents the average load over the last 1 minute.
- Logical Cores Information:
  - Primary Source: `/sys/fs/cgroup/cpu.max`
  - Fallback Sources: `/sys/fs/cgroup/cpu/cpu.cfs_quota_us`, `/sys/fs/cgroup/cpu/cpu.cfs_period_us`

The number of cores is calculated by dividing the quota by the period .

Actions: Check the CPU load on the nodes.

COMPUTE_POOL

Pool usage is over than 90%, Pool usage is over than 95%, Pool usage is over than 99%

Description: One of the pools' CPUs is overloaded.

Actions: Add cores to the configuration of the actor system for the corresponding CPU pool.

NODE_UPTIME

The number of node restarts has increased

Description: The number of node restarts has exceeded the threshold. By default, this is set to 10 restarts per hour.

Actions: Check the logs to determine the reasons for the process restarts.

Node is restarting too often

Description: The number of node restarts has exceeded the threshold. By default, this is set to 30 restarts per hour.

Actions: Check the logs to determine the reasons for the process restarts.

NODES_TIME_DIFFERENCE

Node is ... ms behind peer [id], Node is ... ms ahead of peer [id]

Description: Time drift on nodes might lead to potential issues with coordinating distributed transactions. This issue starts to appear when the time difference is 5 ms or more.

Actions: Check for discrepancies in system time between the nodes listed in the alert, and verify the operation of the time synchronization process.

Examples

The shortest `HealthCheck` response looks like this. It is returned if there is nothing wrong with the database:

```
{
  "self_check_result": "GOOD"
}
```

Verbose example

`GOOD` response with `verbose` parameter:

```
{
    "self_check_result": "GOOD",
    "database_status": [
        {
            "name": "/amy/db",
            "overall": "GREEN",
            "storage": {
                "overall": "GREEN",
                "pools": [
                    {
                        "id": "/amy/db:ssdencrypted",
                        "overall": "GREEN",
                        "groups": [
                            {
                                "id": "2181038132",
                                "overall": "GREEN",
                                "vdisks": [
                                    {
                                        "id": "9-1-1010",
                                        "overall": "GREEN",

Observability in YDB SDK

This section describes how to enable YDB SDK diagnostic tools — logging, metrics, and distributed tracing. It is recommended to enable them in advance, before problems occur, so that when investigating an incident you can see the full picture of the system state before, during, and after the failure.

Logging:

- Enabling logging
- Exporting logs to OpenTelemetry

Metrics:

- Metrics with OpenTelemetry
- Enabling metrics in Prometheus

Tracing:

- Tracing with OpenTelemetry
- Enabling tracing in Jaeger

Server-side observability YDB, which is independent of the SDK, is described in the Reference on YDB observability section.

Enabling logging

Below are code examples for enabling logging in different YDB SDKs.

C++

This functionality is not currently supported.

Go

Native SDK

There are several ways to enable logging in an application that uses `ydb-go-sdk`:

Via variable environment `YDB_LOG_SEVERITY_LEVEL`

This environment variable enables the built-in `ydb-go-sdk` logger (synchronous, non-blocking) with output to the standard output stream.
You can set the environment variable as follows:

```
export YDB_LOG_SEVERITY_LEVEL=info
```

(available values `trace`, `debug`, `info`, `warn`, `error`, `fatal`, `quiet`, default `quiet`).

Connect third-party logger `go.uber.org/zap`

```
package main

import (
  "context"
  "os"

  "go.uber.org/zap"

  ydbZap "github.com/ydb-platform/ydb-go-sdk-zap"
  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/trace"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  var log *zap.Logger // zap-logger with init out of this scope
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydbZap.WithTraces(
      log,
      trace.DetailsAll,
    ),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  ...
}
```

Connect third-party logger `github.com/rs/zerolog`

```
package main

import (
  "context"
  "os"

  "github.com/rs/zerolog"

  ydbZerolog "github.com/ydb-platform/ydb-go-sdk-zerolog"
  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/trace"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  var log zerolog.Logger // zap-logger with init out of this scope
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydbZerolog.WithTraces(
      &log,
      trace.DetailsAll,
    ),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  ...
}
```

Connect own implementation logger `github.com/ydb-platform/ydb-go-sdk/v3/log.Logger`

```
package main

import (
  "context"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/log"
  "github.com/ydb-platform/ydb-go-sdk/v3/trace"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  var logger log.Logger // logger implementation with init out of this scope
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithLogger(
      logger,
      trace.DetailsAll,
    ),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  ...
}
```

Implement own package logging

You can implement your own logging package based on driver events in the `github.com/ydb-platform/ydb-go-sdk/v3/trace` tracing package. The `github.com/ydb-platform/ydb-go-sdk/v3/trace` tracing package contains descriptions of all logged driver events.

Implement obtaining information about server errors `IterateByIssues`

When working with YDB via the Go SDK, you can not only enable logging of requests and responses, but also programmatically obtain detailed information about server errors (issues) — additional messages that YDB returns as part of the response when operations fail. To iterate over the list of issues contained in the server response, use the IterateByIssues method.

database/sql

There are several ways to enable logging in an application that uses `ydb-go-sdk`:

Via variable environment `YDB_LOG_SEVERITY_LEVEL`

This environment variable enables the built-in `ydb-go-sdk` logger (synchronous, non-blocking) with output to the standard output stream.
You can set the environment variable as follows:

```
export YDB_LOG_SEVERITY_LEVEL=info
```

(available values `trace`, `debug`, `info`, `warn`, `error`, `fatal`, `quiet`, default `quiet`).

Connect third-party logger `go.uber.org/zap`

```
package main

import (
  "context"
  "database/sql"
  "os"

  "go.uber.org/zap"

  ydbZap "github.com/ydb-platform/ydb-go-sdk-zap"
  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/trace"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  var log *zap.Logger // zap-logger with init out of this scope
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydbZap.WithTraces(
      log,
      trace.DetailsAll,
    ),
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)

  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }
  defer connector.Close()

  db := sql.OpenDB(connector)
  defer db.Close()
  ...
}
```

Connect third-party logger `github.com/rs/zerolog`

```
package main

import (
  "context"
  "database/sql"
  "os"

  "github.com/rs/zerolog"

  ydbZerolog "github.com/ydb-platform/ydb-go-sdk-zerolog"
  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/trace"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  var log zerolog.Logger // zap-logger with init out of this scope
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydbZerolog.WithTraces(
      &log,
      trace.DetailsAll,
    ),
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)

  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }
  defer connector.Close()

  db := sql.OpenDB(connector)
  defer db.Close()
  ...
}
```

Connect own implementation logger `github.com/ydb-platform/ydb-go-sdk/v3/log.Logger`

```
package main

import (
  "context"
  "database/sql"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/log"
  "github.com/ydb-platform/ydb-go-sdk/v3/trace"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  var logger log.Logger // logger implementation with init out of this scope
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithLogger(
      logger,
      trace.DetailsAll,
    ),
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)

  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }
  defer connector.Close()

  db := sql.OpenDB(connector)
  defer db.Close()
  ...
}
```

Implement own package logging

You can implement your own logging package based on driver events in the `github.com/ydb-platform/ydb-go-sdk/v3/trace` tracing package. The `github.com/ydb-platform/ydb-go-sdk/v3/trace` tracing package contains descriptions of all logged driver events.

Java

Native SDK

The YDB Java SDK uses the slf4j library for logging, which allows using different logging levels (`error` , `warn` , `info` , `debug` , `trace`) for one or more loggers. The following loggers are available in the current implementation:

- The `tech.ydb.core.grpc` logger provides information about the internal implementation of the gRPC protocol
- The `debug` level logs all operations over the gRPC protocol; it is recommended to use only for debugging
- The `info` level is recommended for use by default
- The `tech.ydb.table.impl` logger at the `debug` level allows tracking the internal state of the YDB driver, in particular the session pool operation.
- The `tech.ydb.table.SessionRetryContext` logger at the `debug` level will inform about the number of retries, results of executed queries, execution time of individual retries, and the total execution time of the entire operation
- The `tech.ydb.table.Session` logger at the `debug` level provides information about the query text, response status, and execution time for various session operations

Enabling and configuring Java SDK loggers depends on the `slf4j-api` implementation used.
Here is an example of `log4j2` configuration for the `log4j-slf4j-impl` library

```
<Configuration status="WARN">
  <Appenders>
    <Console name="Console" target="SYSTEM_OUT">
      <PatternLayout pattern="%d{HH:mm:ss.SSS} [%t] %-5level %logger{36} - %msg%n"/>
    </Console>
  </Appenders>

  <Loggers>
    <Logger name="io.netty" level="warn" additivity="false">
      <AppenderRef ref="Console"/>
    </Logger>
    <Logger name="io.grpc.netty" level="warn" additivity="false">
      <AppenderRef ref="Console"/>
    </Logger>
    <Logger name="tech.ydb.core.grpc" level="info" additivity="false">
      <AppenderRef ref="Console"/>
    </Logger>
    <Logger name="tech.ydb.table.impl" level="info" additivity="false">
      <AppenderRef ref="Console"/>
    </Logger>
    <Logger name="tech.ydb.table.SessionRetryContext" level="debug" additivity="false">
      <AppenderRef ref="Console"/>
    </Logger>
    <Logger name="tech.ydb.table.Session" level="debug" additivity="false">
      <AppenderRef ref="Console"/>
    </Logger>

    <Root level="debug" >
      <AppenderRef ref="Console"/>
    </Root>
  </Loggers>
</Configuration>
```

JDBC

The JDBC driver uses the same logging stack via `slf4j` ; configure the `tech.ydb.*` loggers the same way as in the native SDK.

The same debug logs are available in all other frameworks around JDBC (Spring Boot, ORM, connection pools, etc.): they go to YDB through this driver; just connect the same `slf4j` / log4j2 / logback configuration in the application.

Python

The Python SDK uses the standard logging library — `logging` . To enable a specific logging mode:

```
import logging

logging.getLogger('ydb').setLevel(logging.DEBUG)
```

JavaScript

For logging events inside the SDK, the debug library is used.
To enable logs, set the `DEBUG` environment variable with the SDK event filter value — `DEBUG=ydbjs:*` .

Rust

Inside the `ydb` crate, messages go through the standard Rust ecosystem library `tracing` (this is the crate name; it also includes regular text logs at debug/trace level, not just "distributed tracing"). To see output in the console, before creating the client, attach a subscriber, for example `tracing_subscriber::fmt` with the required level (`TRACE` for maximum detail). Example: `basic-logs.rs` .

```
tracing_subscriber::fmt()
    .with_max_level(tracing::Level::TRACE)
    .init();

let client = ydb::ClientBuilder::new_from_connection_string("grpc://localhost:2136?database=local")?
    .client()?;
```

C#

In the YDB C# SDK, logging is connected via the standard `ILoggerFactory` interface from `Microsoft.Extensions.Logging`. You can pass any implementation — a console logger, Serilog, NLog, and others:

```
using Microsoft.Extensions.Logging;
using Ydb.Sdk.Ado;

var loggerFactory = LoggerFactory.Create(builder =>
    builder.AddConsole().SetMinimumLevel(LogLevel.Debug));

var ydbBuilder = new YdbConnectionStringBuilder
{
    Host = "localhost",
    Port = 2136,
    Database = "/local",
    LoggerFactory = loggerFactory
};

await using var dataSource = new YdbDataSource(ydbBuilder);
await using var connection = await dataSource.OpenConnectionAsync();
```

Since `LoggerFactory` accepts the standard `ILoggerFactory`, you can connect Serilog or NLog without additional adapters:

```
// Serilog
var loggerFactory = new SerilogLoggerFactory(Log.Logger);

// NLog
var loggerFactory = LoggerFactory.Create(builder => builder.AddNLog());
```

PHP

In the YDB PHP SDK, for logging you need to use a class that implements `\Psr\Log\LoggerInterface`.
The YDB-PHP-SDK includes built-in loggers in the `YdbPlatform\Ydb\Logger` namespace:

- `NullLogger` - the default one that outputs nothing
- `SimpleStdLogger($level)` - a logger that outputs logs to stderr.

Usage example:

```
$config = [
  'logger' => new \YdbPlatform\Ydb\Logger\SimpleStdLogger(\YdbPlatform\Ydb\Logger\SimpleStdLogger::INFO)
]
$ydb = new \YdbPlatform\Ydb\Ydb($config);
```

Exporting logs to OpenTelemetry

Each YDB SDK writes its own internal logs (driver initialization, session pool, query execution, retries, etc.) through the standard logging facility of its language. Instead of outputting logs only to the console (see Enable logging), they can be redirected to the OpenTelemetry Logs SDK and exported via the standard OTLP protocol to a collector. The collector then forwards the records to the chosen backend for log storage and viewing.

The principle is the same in all SDKs:

1. Create an OpenTelemetry `LoggerProvider` with an OTLP log exporter and the `service.name` resource attribute.
2. Redirect the SDK logger to this provider through an adapter (log appender / bridge) that converts each SDK log record into an OTel log record. For the list of adapters and the status of log support in different languages, see the OpenTelemetry logging documentation.
3. Run the workload — all internal SDK logs are now sent to the collector as OTLP log records.

> **Note**
>
> ### Principles
>
> The method of log collection depends on the language and infrastructure — there is no single format:
>
> - **Programmatic bridges (log appender / bridge).** The application itself sends logs to the collector via OTLP directly from the process (direct-to-Collector workflow). This is the approach shown in the examples below.
> - **Collector agents.** The application writes logs to a file or `stdout`, and a separate agent (e.g., the filelog receiver in the OpenTelemetry Collector) reads, parses, and forwards them to the backend — without changing the application code.

Connecting to the SDK

C++

YDB The YDB C++ SDK writes logs through `TLogBackend` from `util`. Implement a backend that converts each record into an OTel log record, and pass it to the driver via `TDriverConfig::SetLog`. For building the OpenTelemetry C++ SDK, see Getting Started.

```cpp
#include <ydb-cpp-sdk/client/driver/driver.h>
#include <opentelemetry/exporters/otlp/otlp_grpc_log_record_exporter_factory.h>
#include <opentelemetry/exporters/otlp/otlp_grpc_log_record_exporter_options.h>
#include <opentelemetry/logs/provider.h>
#include <opentelemetry/sdk/logs/batch_log_record_processor_factory.h>
#include <opentelemetry/sdk/logs/logger_provider_factory.h>
#include <opentelemetry/sdk/resource/resource.h>
#include <library/cpp/logger/backend.h>
#include <library/cpp/logger/record.h>
#include <memory>

namespace otlp     = opentelemetry::exporter::otlp;
namespace logs_sdk = opentelemetry::sdk::logs;
namespace logs_api = opentelemetry::logs;
namespace resource = opentelemetry::sdk::resource;

namespace {

class TOtelLogBackend final : public TLogBackend {
public:
  explicit TOtelLogBackend(opentelemetry::nostd::shared_ptr<logs_api::Logger> logger)
      : Logger_(std::move(logger)) {}

  void WriteData(const TLogRecord& rec) override {
      Logger_->EmitLogRecord(MapSeverity(rec.Priority),
                             opentelemetry::nostd::string_view(rec.Data, rec.Len));
  }

  void ReopenLog() override {}

private:
  static logs_api::Severity MapSeverity(ELogPriority p) {
      switch (p) {
          case TLOG_EMERG:
          case TLOG_ALERT:
          case TLOG_CRIT:    return logs_api::Severity::kFatal;
          case TLOG_ERR:     return logs_api::Severity::kError;
          case TLOG_WARNING: return logs_api::Severity::kWarn;
          case TLOG_NOTICE:
          case TLOG_INFO:    return logs_api::Severity::kInfo;
          case TLOG_DEBUG:   return logs_api::Severity::kDebug;
          default:           return logs_api::Severity::kTrace;
      }
  }

  opentelemetry::nostd::shared_ptr<logs_api::Logger> Logger_;
};
} // namespace

int main() {
  // 1. Configuring the OTel log provider with an OTLP exporter
  otlp::OtlpGrpcLogRecordExporterOptions exporterOpts;
  exporterOpts.endpoint = "localhost:4317";
  auto exporter  = otlp::OtlpGrpcLogRecordExporterFactory::Create(exporterOpts);
  auto processor = logs_sdk::BatchLogRecordProcessorFactory::Create(std::move(exporter));
  auto res       = resource::Resource::Create({{"service.name", "ydb-cpp-sdk-otel-logs-sample"}});

  std::shared_ptr<logs_api::LoggerProvider> provider(
      logs_sdk::LoggerProviderFactory::Create(std::move(processor), res));
  logs_api::Provider::SetLoggerProvider(provider);

  auto logger = provider->GetLogger("ydb-cpp-sdk");

  // 2. Passing the bridge to the YDB driver
  auto config = NYdb::TDriverConfig()
      .SetEndpoint("localhost:2136")
      .SetDatabase("/local")
      .SetLog(std::make_unique<TOtelLogBackend>(logger));

  NYdb::TDriver driver(config);
  // ... use driver ...
  driver.Stop(true);
}
```

Go

For the YDB Go SDK, there is a ready-made adapter ydb-go-sdk-otel that converts SDK events into OpenTelemetry signals: traces (`WithTracer`), metrics (`WithMetrics`), and logs (`WithLogger`). The adapter does not configure exporters itself — you create a `LoggerProvider` with an OTLP log exporter, obtain a logger from it, and pass it to the `ydbOtel.WithLogger` option when calling `ydb.Open`. Each internal SDK log record (driver initialization, session pool, query execution, retries, etc.) is then sent to the collector as an OTLP log record.

```
go get github.com/ydb-platform/ydb-go-sdk-otel
go get go.opentelemetry.io/otel/sdk/log
go get go.opentelemetry.io/otel/exporters/otlp/otlplog/otlploggrpc
```

```go
package main

import (
    "context"
    "os"

    "github.com/ydb-platform/ydb-go-sdk/v3"
    "github.com/ydb-platform/ydb-go-sdk/v3/trace"

    "go.opentelemetry.io/otel/attribute"
    "go.opentelemetry.io/otel/exporters/otlp/otlplog/otlploggrpc"
    sdklog "go.opentelemetry.io/otel/sdk/log"
    "go.opentelemetry.io/otel/sdk/resource"

    ydbOtel "github.com/ydb-platform/ydb-go-sdk-otel"
)

func main() {
    ctx := context.Background()

    // 1. Configuring the OTel log provider with an OTLP exporter.
    exporter, err := otlploggrpc.New(ctx,
        otlploggrpc.WithEndpoint("localhost:4317"),
        otlploggrpc.WithInsecure(),
    )
    if err != nil {
        panic(err)
    }
    res, _ := resource.Merge(resource.Default(), resource.NewSchemaless(
        attribute.String("service.name", "ydb-go-sdk-otel-logs-sample"),
    ))
    lp := sdklog.NewLoggerProvider(
        sdklog.WithResource(res),
        sdklog.WithProcessor(sdklog.NewBatchProcessor(exporter)),
    )
    defer lp.Shutdown(ctx)

    // 2. Opening the YDB driver with the ydb-go-sdk-otel adapter.
    // WithLogger forwards SDK log events to OTel log records.
    logger := lp.Logger("ydb-go-sdk")
    db, err := ydb.Open(ctx,
        os.Getenv("YDB_CONNECTION_STRING"),
        ydbOtel.WithLogger(logger, ydbOtel.WithDetailer(trace.DetailsAll)),
    )
    if err != nil {
        panic(err)
    }
    defer db.Close(ctx)
    // ... use db ...
}
```

Java

YDB Java SDK writes logs via `slf4j`. If logback is used as the `slf4j` implementation, connect the ready-made `opentelemetry-logback-appender-1.0` appender, which forwards each event to the OpenTelemetry Logs SDK:

```xml
<dependency>
    <groupId>io.opentelemetry</groupId>
    <artifactId>opentelemetry-sdk</artifactId>
    <version>${otel.version}</version>
</dependency>
<dependency>
    <groupId>io.opentelemetry</groupId>
    <artifactId>opentelemetry-exporter-otlp</artifactId>
    <version>${otel.version}</version>
</dependency>
<dependency>
    <groupId>io.opentelemetry.instrumentation</groupId>
    <artifactId>opentelemetry-logback-appender-1.0</artifactId>
    <version>${otel.instrumentation.version}</version>
</dependency>
<dependency>
    <groupId>ch.qos.logback</groupId>
    <artifactId>logback-classic</artifactId>
    <version>${logback.version}</version>
</dependency>
```

Connect the appender in `logback.xml`:

```xml
<configuration>
    <appender name="OTEL" class="io.opentelemetry.instrumentation.logback.appender.v1_0.OpenTelemetryAppender">
    </appender>

    <root level="INFO">
        <appender-ref ref="OTEL"/>
    </root>
</configuration>
```

Build an OpenTelemetry SDK instance with an OTLP log exporter and set it in the appender by calling `OpenTelemetryAppender.install(...)` before starting the workload:

```
import java.util.concurrent.TimeUnit;

import io.opentelemetry.api.OpenTelemetry;
import io.opentelemetry.api.common.Attributes;
import io.opentelemetry.exporter.otlp.logs.OtlpGrpcLogRecordExporter;
import io.opentelemetry.instrumentation.logback.appender.v1_0.OpenTelemetryAppender;
import io.opentelemetry.sdk.OpenTelemetrySdk;
import io.opentelemetry.sdk.logs.SdkLoggerProvider;
import io.opentelemetry.sdk.logs.export.BatchLogRecordProcessor;
import io.opentelemetry.sdk.resources.Resource;
import tech.ydb.core.grpc.GrpcTransport;
import tech.ydb.query.QueryClient;

String serviceName = "ydb-java-sdk-otel-logs-sample";
Resource resource = Resource.getDefault().merge(
        Resource.create(Attributes.builder().put("service.name", serviceName).build()));

SdkLoggerProvider loggerProvider = SdkLoggerProvider.builder()
        .setResource(resource)
        .addLogRecordProcessor(BatchLogRecordProcessor.builder(
                OtlpGrpcLogRecordExporter.builder().setEndpoint("http://localhost:4317").build()
        ).build())
        .build();

OpenTelemetry openTelemetry = OpenTelemetrySdk.builder()
        .setLoggerProvider(loggerProvider)
        .build();

// Passing the OpenTelemetry SDK to the appender declared in logback.xml.
OpenTelemetryAppender.install(openTelemetry);

try (GrpcTransport transport = GrpcTransport.forConnectionString("grpc://localhost:2136/local").build();
     QueryClient queryClient = QueryClient.newClient(transport).build()) {
    // ... use queryClient ...
} finally {
    loggerProvider.forceFlush().join(10, TimeUnit.SECONDS);
    loggerProvider.shutdown().join(10, TimeUnit.SECONDS);
}
```

Python

YDB Python SDK writes logs via the standard `logging` module (loggers named `ydb.*`). Use the built-in OpenTelemetry `LoggingHandler` to redirect these records to `LoggerProvider` and export via OTLP:

```
pip install opentelemetry-sdk opentelemetry-exporter-otlp-proto-grpc
```

```
import logging

import ydb
from opentelemetry._logs import set_logger_provider
from opentelemetry.exporter.otlp.proto.grpc._log_exporter import OTLPLogExporter
from opentelemetry.sdk._logs import LoggerProvider, LoggingHandler
from opentelemetry.sdk._logs.export import BatchLogRecordProcessor
from opentelemetry.sdk.resources import Resource

resource = Resource(attributes={"service.name": "ydb-otel-logs-example"})
logger_provider = LoggerProvider(resource=resource)
logger_provider.add_log_record_processor(
    BatchLogRecordProcessor(OTLPLogExporter(endpoint="http://localhost:4317"))
)
set_logger_provider(logger_provider)

# Bridge stdlib logging -> OpenTelemetry. Binding the handler to the root logger
# intercepts everything that the SDK writes via logging.getLogger("ydb...").
otel_handler = LoggingHandler(level=logging.NOTSET, logger_provider=logger_provider)
logging.basicConfig(level=logging.INFO, handlers=[otel_handler])
logging.getLogger("ydb").setLevel(logging.INFO)

with ydb.Driver(endpoint="grpc://localhost:2136", database="/local") as driver:
    driver.wait(timeout=5)
    with ydb.QuerySessionPool(driver) as pool:
        pool.execute_with_retries("SELECT 1")

logger_provider.shutdown()
```

C#

YDB C# SDK writes logs via the `ILoggerFactory` passed to it. Create a factory based on the OpenTelemetry logging provider with an OTLP exporter and pass it to the data source:

```
dotnet add package OpenTelemetry
dotnet add package OpenTelemetry.Exporter.OpenTelemetryProtocol
```

```
using Microsoft.Extensions.Logging;
using OpenTelemetry.Logs;
using OpenTelemetry.Resources;
using Ydb.Sdk.Ado;

var resourceBuilder = ResourceBuilder.CreateDefault()
    .AddService("ydb-sdk-otel-logs-sample");

using var loggerFactory = LoggerFactory.Create(builder =>
{
    builder.AddOpenTelemetry(options =>
    {
        options.SetResourceBuilder(resourceBuilder);
        options.AddOtlpExporter(o => o.Endpoint = new Uri("http://localhost:4317"));
    });
});

// Passing the factory to the SDK: each internal log (driver initialization, session pool,
// query execution, retries, ...) is exported to the collector as an OTLP log record.
await using var dataSource = new YdbDataSource(
    new YdbConnectionStringBuilder("Host=localhost;Port=2136;Database=/local")
    {
        LoggerFactory = loggerFactory
    });

await using var connection = await dataSource.OpenConnectionAsync();
await new YdbCommand("SELECT 1", connection).ExecuteNonQueryAsync();
```

JavaScript

This functionality is not currently supported.

Rust

This functionality is not currently supported.

Track progress or vote for support in the Rust SDK: ydb-rs-sdk#268

PHP

This functionality is not currently supported.

Metrics with OpenTelemetry

YDB SDK instruments Query Service operations with OpenTelemetry metrics, allowing you to observe the client state — operation duration and count, session pool state — from application code to gRPC calls to YDB. Metrics are exported via the standard OTLP protocol and are compatible with Prometheus, Grafana, VictoriaMetrics, and any other backend that supports OpenTelemetry.

List of metrics

Operation metrics

Name	Type	Unit	Description
`ydb.client.operation.duration`	Histogram	`s`	Duration of a single client operation attempt (`ExecuteQuery`, `Commit`, `Rollback`, `CreateSession`).
`ydb.client.operation.failed`	Counter	`{operation}`	Number of unsuccessful client operations.

Session pool metrics

Name	Type	Unit	Description
`ydb.query.session.create_time`	Histogram	`s`	Duration of creating a new session.
`ydb.query.session.pending_requests`	Counter	`{request}`	Monotonic counter of requests for session acquisition that entered the wait queue since the pool was created.
`ydb.query.session.timeouts`	Counter	`{timeout}`	Monotonic counter of timeouts when waiting for a free session, since the pool was created.
`ydb.query.session.count`	Gauge	`{session}`	Current number of sessions in the pool, broken down by state.
`ydb.query.session.min`	Gauge	`{session}`	Configured minimum session pool size.
`ydb.query.session.max`	Gauge	`{session}`	Configured maximum size of the session pool.

Retry metrics

Name	Type	Unit	Description
`ydb.client.retry.duration`	Histogram	`s`	Total client-visible duration of a logical operation performed through a retry policy, including all attempts and backoff delays.
`ydb.client.retry.attempts`	Histogram	`{attempt}`	Distribution of the number of attempts per logical operation. The value `1` means success on the first attempt.

Attributes

Name	Applies to	Value
`database`	`ydb.client.operation.duration`, `ydb.client.operation.failed`	Database name YDB.
`endpoint`	`ydb.client.operation.duration`, `ydb.client.operation.failed`	Discovery-endpoint in the format `host:port`.
`operation.name`	`ydb.client.operation.duration`, `ydb.client.operation.failed`, `ydb.client.retry.duration`, `ydb.client.retry.attempts`	Client operation name: `ExecuteQuery`, `Commit`, `Rollback`, `CreateSession`.
`status_code`	`ydb.client.operation.failed`	Status code YDB (for example, `BAD_REQUEST`, `SCHEME_ERROR`).
`ydb.query.session.pool.name`	All `ydb.query.session.*` metrics	Session pool name. By default, it is formed as `<endpoint>/<database>` and configured through the API of a specific SDK.
`ydb.query.session.state`	`ydb.query.session.count`	Session state: `idle` or `used`.

Connecting to the SDK

C++

Include the OpenTelemetry metrics header from YDB C++ SDK and register `MetricRegistry` in `TDriverConfig`:

```cpp
#include <ydb-cpp-sdk/client/driver/driver.h>
#include <ydb-cpp-sdk/open_telemetry/metrics.h>

#include <opentelemetry/exporters/otlp/otlp_http_metric_exporter_factory.h>
#include <opentelemetry/exporters/otlp/otlp_http_metric_exporter_options.h>
#include <opentelemetry/sdk/metrics/meter_provider.h>
#include <opentelemetry/sdk/metrics/view/view_registry.h>
#include <opentelemetry/sdk/metrics/export/periodic_exporting_metric_reader_factory.h>
#include <opentelemetry/sdk/resource/resource.h>
#include <opentelemetry/metrics/provider.h>

namespace sdkmetrics = opentelemetry::sdk::metrics;
namespace otlp      = opentelemetry::exporter::otlp;
namespace resource  = opentelemetry::sdk::resource;
using namespace NYdb;

// 1. Initialize the OTel metrics provider
otlp::OtlpHttpMetricExporterOptions opts;
opts.url = "http://localhost:4318/v1/metrics";

auto exporter = otlp::OtlpHttpMetricExporterFactory::Create(opts);

sdkmetrics::PeriodicExportingMetricReaderOptions readerOpts;
readerOpts.export_interval_millis = std::chrono::milliseconds(5000);
auto reader = sdkmetrics::PeriodicExportingMetricReaderFactory::Create(
    std::move(exporter), readerOpts);

auto res = resource::Resource::Create({{"service.name", "my-service"}});
auto rawProvider = std::make_shared<sdkmetrics::MeterProvider>(
    std::unique_ptr<sdkmetrics::ViewRegistry>(new sdkmetrics::ViewRegistry()), res);
rawProvider->AddMetricReader(std::move(reader));

std::shared_ptr<opentelemetry::metrics::MeterProvider> meterProvider = rawProvider;
opentelemetry::metrics::Provider::SetMeterProvider(meterProvider);

// 2. Wrap in the YDB metrics registry
auto ydbMetricRegistry = NMetrics::CreateOtelMetricRegistry(meterProvider);

// 3. Create a YDB driver with metrics enabled
auto driverConfig = TDriverConfig()
    .SetEndpoint("localhost:2136")
    .SetDatabase("/local")
    .SetMetricRegistry(ydbMetricRegistry);

TDriver driver(driverConfig);
```

Metrics and tracing can be enabled together by registering both `MetricRegistry` and `TraceProvider` in `TDriverConfig`.

Go

Install the OpenTelemetry adapter for the YDB Go SDK:

```
go get github.com/ydb-platform/ydb-go-sdk-otel
```

Configure `MeterProvider`, get `Meter` from it, and pass it to the `ydbOtel.WithMetrics` adapter, which connects to the driver via the `ydb.Open` option. The granularity of collected metrics can be configured via `ydbOtel.WithDetailer`:

```go
package main

import (
    "context"
    "os"

    "go.opentelemetry.io/otel"
    "go.opentelemetry.io/otel/attribute"
    "go.opentelemetry.io/otel/exporters/otlp/otlpmetric/otlpmetricgrpc"
    "go.opentelemetry.io/otel/sdk/metric"
    "go.opentelemetry.io/otel/sdk/resource"

    "github.com/ydb-platform/ydb-go-sdk/v3"
    "github.com/ydb-platform/ydb-go-sdk/v3/trace"
    ydbOtel "github.com/ydb-platform/ydb-go-sdk-otel"
)

func main() {
    ctx := context.Background()

    exporter, err := otlpmetricgrpc.New(ctx,
        otlpmetricgrpc.WithEndpoint("localhost:4317"),
        otlpmetricgrpc.WithInsecure(),
    )
    if err != nil {
        panic(err)
    }
    res, _ := resource.Merge(resource.Default(), resource.NewSchemaless(
        attribute.String("service.name", "my-service"),
    ))
    mp := metric.NewMeterProvider(
        metric.WithReader(metric.NewPeriodicReader(exporter)),
        metric.WithResource(res),
    )
    defer mp.Shutdown(ctx)
    otel.SetMeterProvider(mp)

    db, err := ydb.Open(ctx,
        os.Getenv("YDB_CONNECTION_STRING"),
        ydbOtel.WithMetrics(
            mp.Meter("ydb-go-sdk"),
            ydbOtel.WithDetailer(trace.DetailsAll),
        ),
    )
    if err != nil {
        panic(err)
    }
    defer db.Close(ctx)
}
```

Java

> **Note**
>
> In the Java SDK, only session pool metrics are currently supported.

Pass your `OpenTelemetry` to the SDK via the `OpenTelemetryMeter` adapter and the `QueryClient.Builder#withMeter` method:

```
import io.opentelemetry.api.OpenTelemetry;
import io.opentelemetry.exporter.otlp.metrics.OtlpGrpcMetricExporter;
import io.opentelemetry.sdk.OpenTelemetrySdk;
import io.opentelemetry.sdk.metrics.SdkMeterProvider;
import io.opentelemetry.sdk.metrics.export.PeriodicMetricReader;

import tech.ydb.core.grpc.GrpcTransport;
import tech.ydb.core.metrics.OpenTelemetryMeter;
import tech.ydb.query.QueryClient;

SdkMeterProvider meterProvider = SdkMeterProvider.builder()
    .registerMetricReader(PeriodicMetricReader
        .builder(OtlpGrpcMetricExporter.getDefault())
        .build())
    .build();

OpenTelemetry openTelemetry = OpenTelemetrySdk.builder()
    .setMeterProvider(meterProvider)
    .build();

try (GrpcTransport transport = GrpcTransport
        .forConnectionString(System.getenv("YDB_CONNECTION_STRING"))
        .build();
     QueryClient queryClient = QueryClient.newClient(transport)
        .withMeter(OpenTelemetryMeter.fromOpenTelemetry(openTelemetry))
        .sessionPoolName("my-app")
        .build()) {
    // Use queryClient
}
meterProvider.close();
```

If you have already configured a global `GlobalOpenTelemetry`, you can use `OpenTelemetryMeter.createGlobal()`. `TableClient` also supports `withMeter(...)`.

Python

This functionality is not currently supported.

C#

Add the NuGet package:

```
dotnet add package Ydb.Sdk.OpenTelemetry
```

Register the YDB instrumentation in the OpenTelemetry metrics pipeline:

```
services.AddOpenTelemetry()
    .WithMetrics(builder => builder
        .AddYdb()
        .AddOtlpExporter());
```

Or using a standalone `MeterProvider`:

```
using var meterProvider = Sdk.CreateMeterProviderBuilder()
    .SetResourceBuilder(ResourceBuilder.CreateDefault().AddService("my-service"))
    .AddYdb()
    .AddOtlpExporter()
    .Build();
```

The session pool name is set by the `PoolName=` parameter in the `YdbDataSource` connection string. A full example with load and Grafana is in the SDK repository (Ydb.Sdk.AdoNet.OpenTelemetry/Metrics).

JavaScript

Install the YDB JavaScript SDK telemetry package and OpenTelemetry SDK:

```
npm install @ydbjs/telemetry @opentelemetry/sdk-node @opentelemetry/exporter-metrics-otlp-http
```

Initialize `NodeSDK` before creating `Driver` and register the instrumentation `@ydbjs/telemetry`:

```
import { NodeSDK } from '@opentelemetry/sdk-node'
import { OTLPMetricExporter } from '@opentelemetry/exporter-metrics-otlp-http'
import { PeriodicExportingMetricReader } from '@opentelemetry/sdk-metrics'
import { Driver } from '@ydbjs/core'
import { query } from '@ydbjs/query'
import { register } from '@ydbjs/telemetry'

const sdk = new NodeSDK({
    serviceName: 'my-service',
    metricReader: new PeriodicExportingMetricReader({
        exporter: new OTLPMetricExporter({
            url: 'http://localhost:4318/v1/metrics',
        }),
    }),
})
sdk.start()

// Must be called BEFORE creating the Driver: the package subscribes to
// diagnostics_channel SDK events and converts them to OTel metrics.
const instrumentation = register()

const driver = new Driver(process.env.YDB_CONNECTION_STRING)
await driver.ready()

const sql = query(driver)
await sql`SELECT 1`

instrumentation.disable()
await driver.close()
await sdk.shutdown()
```

Package `@ydbjs/telemetry` subscribes to events `node:diagnostics_channel` from `@ydbjs/core`, `@ydbjs/query`, `@ydbjs/auth`, and `@ydbjs/retry` and publishes metrics from the list above. Operation duration is exported as `db.client.operation.duration` (OpenTelemetry semantic conventions), not `ydb.client.operation.duration`. The current number of requests waiting for a session is gauge `ydb.query.session.acquire.pending`, not counter `ydb.query.session.pending_requests`. For more details, see the JavaScript SDK repository.

In addition, the JavaScript SDK publishes its own retry metrics with names and semantics different from `ydb.client.retry.*`:

Name	Type	Unit	Description
`ydb.retry.attempts`	Counter	`{attempt}`	Monotonic counter of retry attempts with outcome tag `ydb.retry.outcome` (e.g., `success`, `retried`). Unlike the `ydb.client.retry.attempts` histogram, it does not show the distribution of the number of attempts per query.
`ydb.retry.duration`	Histogram	`s`	Total duration of the retry cycle, including backoff (analogous to `ydb.client.retry.duration`).

Rust

This functionality is not currently supported.

Track progress or vote for support in the Rust SDK: ydb-rs-sdk#268

PHP

This functionality is not currently supported.

Enabling metrics in Prometheus

Below are code examples for enabling metrics in Prometheus in different YDB SDKs.

C++

This feature is not currently supported.

Go

Native SDK

```
package main

import (
    "context"

    "github.com/prometheus/client_golang/prometheus"
    metrics "github.com/ydb-platform/ydb-go-sdk-prometheus/v2"
    "github.com/ydb-platform/ydb-go-sdk/v3"
    "github.com/ydb-platform/ydb-go-sdk/v3/trace"
)

func main() {
    ctx := context.Background()
    registry := prometheus.NewRegistry()
    db, err := ydb.Open(ctx,
        os.Getenv("YDB_CONNECTION_STRING"),
        metrics.WithTraces(
            registry,
            metrics.WithDetails(trace.DetailsAll),
            metrics.WithSeparator("_"),
        ),
    )
    if err != nil {
        panic(err)
    }
    defer db.Close(ctx)
    ...
}
```

database/sql

```
package main

import (
    "context"
    "database/sql"

    "github.com/prometheus/client_golang/prometheus"
    metrics "github.com/ydb-platform/ydb-go-sdk-prometheus/v2"
    "github.com/ydb-platform/ydb-go-sdk/v3"
    "github.com/ydb-platform/ydb-go-sdk/v3/trace"
)

func main() {
    ctx := context.Background()
    registry := prometheus.NewRegistry()
    nativeDriver, err := ydb.Open(ctx,
        os.Getenv("YDB_CONNECTION_STRING"),
        metrics.WithTraces(
            registry,
            metrics.WithDetails(trace.DetailsAll),
            metrics.WithSeparator("_"),
        ),
    )
    if err != nil {
        panic(err)
    }
    defer nativeDriver.Close(ctx)

    connector, err := ydb.Connector(nativeDriver)
    if err != nil {
        panic(err)
    }

    db := sql.OpenDB(connector)
    defer db.Close()
    ...
}
```

Java

This functionality is not currently supported.

Python

This functionality is not currently supported.

C#

This functionality is not currently supported.

JavaScript

This functionality is not currently supported.

Track progress or vote for support in the Rust SDK: ydb-rs-sdk#267

PHP

This functionality is not currently supported.

Tracing with OpenTelemetry

YDB SDK instruments Query Service operations with OpenTelemetry spans, providing distributed tracing from application code to each gRPC call to YDB. Spans are exported via the standard OTLP protocol and are compatible with Jaeger, Grafana Tempo, Zipkin, and any other backend that supports OpenTelemetry.

Created spans

Currently, spans are supported for Query Service operations. Support for topics and other services is planned in future SDK versions.

The following spans are created:

Span	Type	Description
`ydb.RunWithRetry`	`Internal`	Covers the entire retry cycle for a single operation
`ydb.Try`	`Internal`	One span per attempt, including the first; child RPC spans are attached to it
`ydb.CreateSession`	`Client`	Session creation via gRPC `CreateSession` and `AttachStream`
`ydb.ExecuteQuery`	`Client`	Execution of a single YQL query
`ydb.BeginTransaction`	`Client`	Explicit call to begin a transaction
`ydb.Commit`	`Client`	Transaction commit
`ydb.Rollback`	`Client`	Transaction rollback
`ydb.Driver.Initialize`	`Internal`	Driver initialization: cluster discovery and authentication

A typical span tree for a transactional operation with retry looks as follows:

```
ydb.RunWithRetry  (Internal)
├─ ydb.Try        (Internal)   ← 1st attempt: ERROR
│  ├─ ydb.ExecuteQuery (Client)
│  ├─ ydb.ExecuteQuery (Client)
│  └─ ydb.Commit       (Client) ← ERROR: Transaction Lock Invalidated
└─ ydb.Try        (Internal)   ← 2nd attempt: SUCCESS, ydb.retry.backoff_ms=50
   ├─ ydb.ExecuteQuery (Client)
   ├─ ydb.ExecuteQuery (Client)
   └─ ydb.Commit       (Client)
```

`ydb.RunWithRetry` is the parent span for the entire operation with retries. For each execution attempt, a separate child span `ydb.Try` is created: the first `ydb.Try` corresponds to the first attempt, the second to the first **retry**, and so on. RPC spans of a specific attempt, e.g., `ydb.ExecuteQuery` and `ydb.Commit`, are created inside the corresponding `ydb.Try`.

> **Note**
>
> If an attempt fails, its span `ydb.Try` ends with an error status. On retry, a new `ydb.Try` is created; starting from the second attempt, the attribute `ydb.retry.backoff_ms` is set — the wait time before this attempt in milliseconds. This wait is included in the duration of the next span `ydb.Try`: the span starts before the backoff pause, then after the pause, the RPC calls of this attempt are executed.

Span attributes

SDK uses both standard OpenTelemetry semantic conventions attributes and YDB-specific extensions.

Standard OpenTelemetry attributes

The following attributes belong to the stable OpenTelemetry semantic conventions and can be processed by tracing backends as standard:

Attribute	Where set	Description
`db.system.name`	RPC spans	Always `"ydb"`
`db.namespace`	RPC spans	YDB database path
`server.address`	RPC spans	Primary host from the connection string
`server.port`	RPC spans	Primary port from the connection string
`network.peer.address`	RPC spans	Actual gRPC endpoint used for the call
`network.peer.port`	RPC spans	Actual port of the gRPC endpoint used for the call
`error.type`	Spans that ended with an error	Error type. For example: `"transport_error"`, `"ydb_error"`, or the full exception class name
`db.response.status_code`	RPC spans with `YdbException`	Text name of the YDB status from the error, e.g., `ABORTED`, `UNAVAILABLE`, `OVERLOADED`

YDB-specific attributes

The following attributes are YDB extensions on top of the standard semantic conventions:

Attribute	Where set	Description

`ydb.node.id`	RPC spans	ID of the YDB node that processed the request
`ydb.node.dc`	RPC spans	Datacenter of the YDB node that processed the request
`ydb.retry.backoff_ms`	Spans `ydb.Try`, starting from the second attempt	Wait time before retry in milliseconds

W3C trace context

SDK automatically propagates the W3C `traceparent` header in every outgoing gRPC call. This allows the YDB server to trace internal operations within the same trace — without additional configuration. For more details on server-side tracing, see the section Passing an external trace-id to YDB.

Connecting to the SDK

C++

Include the OpenTelemetry tracing header from YDB C++ SDK and add a dependency on the OTel C++ SDK:

```
#include <ydb-cpp-sdk/client/driver/driver.h>
#include <ydb-cpp-sdk/open_telemetry/trace.h>

#include <opentelemetry/exporters/otlp/otlp_http_exporter_factory.h>
#include <opentelemetry/exporters/otlp/otlp_http_exporter_options.h>
#include <opentelemetry/sdk/trace/tracer_provider.h>
#include <opentelemetry/sdk/trace/simple_processor_factory.h>
#include <opentelemetry/sdk/resource/resource.h>
#include <opentelemetry/trace/provider.h>

namespace sdktrace = opentelemetry::sdk::trace;
namespace otlp     = opentelemetry::exporter::otlp;
namespace resource = opentelemetry::sdk::resource;
using namespace NYdb;

// 1. Initialize the OTel tracing provider
otlp::OtlpHttpExporterOptions opts;
opts.url = "http://localhost:4318/v1/traces";
auto exporter  = otlp::OtlpHttpExporterFactory::Create(opts);
auto processor = sdktrace::SimpleSpanProcessorFactory::Create(std::move(exporter));
auto res       = resource::Resource::Create({{"service.name", "my-service"}});
auto otelProvider = std::make_shared<sdktrace::TracerProvider>(
    std::move(processor), res);
opentelemetry::trace::Provider::SetTracerProvider(otelProvider);

// 2. Wrap in the YDB tracing provider
auto ydbTraceProvider = NTrace::CreateOtelTraceProvider(otelProvider);

// 3. Create a YDB driver with tracing enabled
auto driverConfig = TDriverConfig()
    .SetEndpoint("localhost:2136")
    .SetDatabase("/local")
    .SetTraceProvider(ydbTraceProvider);

TDriver driver(driverConfig);
```

Go

Install the OpenTelemetry adapter for the YDB Go SDK:

```
go get github.com/ydb-platform/ydb-go-sdk-otel
```

Configure `TracerProvider` and pass the adapter to `ydb.Open`:

```go
package main

import (
    "context"
    "os"

    "go.opentelemetry.io/otel"
    "go.opentelemetry.io/otel/attribute"
    "go.opentelemetry.io/otel/exporters/otlp/otlptrace/otlptracegrpc"
    "go.opentelemetry.io/otel/sdk/resource"
    sdktrace "go.opentelemetry.io/otel/sdk/trace"

    "github.com/ydb-platform/ydb-go-sdk/v3"
    ydbOtel "github.com/ydb-platform/ydb-go-sdk-otel"
)

func main() {
    ctx := context.Background()

    exporter, err := otlptracegrpc.New(ctx,
        otlptracegrpc.WithEndpoint("localhost:4317"),
        otlptracegrpc.WithInsecure(),
    )
    if err != nil {
        panic(err)
    }
    res, _ := resource.Merge(resource.Default(), resource.NewSchemaless(
        attribute.String("service.name", "my-service"),
    ))
    tp := sdktrace.NewTracerProvider(
        sdktrace.WithBatcher(exporter),
        sdktrace.WithResource(res),
    )
    defer tp.Shutdown(ctx)
    otel.SetTracerProvider(tp)

    db, err := ydb.Open(ctx,
        os.Getenv("YDB_CONNECTION_STRING"),
        ydbOtel.WithTraces(
            ydbOtel.WithTracer(tp.Tracer("ydb-go-sdk")),
        ),
    )
    if err != nil {
        panic(err)
    }
    defer db.Close(ctx)
}
```

Java

Add YDB SDK and OpenTelemetry dependencies (example for Maven):

```xml
<dependency>
    <groupId>tech.ydb</groupId>
    <artifactId>ydb-sdk-core</artifactId>
    <version>${ydb.sdk.version}</version>
</dependency>
<dependency>
    <groupId>io.opentelemetry</groupId>
    <artifactId>opentelemetry-sdk</artifactId>
    <version>${otel.version}</version>
</dependency>
<dependency>
    <groupId>io.opentelemetry</groupId>
    <artifactId>opentelemetry-exporter-otlp</artifactId>
    <version>${otel.version}</version>
</dependency>
```

Create an OpenTelemetry SDK instance and pass it to the transport via `OpenTelemetryTracer`:

```
import io.opentelemetry.api.OpenTelemetry;
import io.opentelemetry.exporter.otlp.trace.OtlpGrpcSpanExporter;
import io.opentelemetry.sdk.OpenTelemetrySdk;
import io.opentelemetry.sdk.resources.Resource;
import io.opentelemetry.sdk.trace.SdkTracerProvider;
import io.opentelemetry.sdk.trace.export.BatchSpanProcessor;
import io.opentelemetry.semconv.resource.attributes.ResourceAttributes;
import tech.ydb.core.auth.CloudAuthHelper;
import tech.ydb.core.grpc.GrpcTransport;
import tech.ydb.core.opentelemetry.OpenTelemetryTracer;
import tech.ydb.query.QueryClient;

Resource resource = Resource.getDefault().toBuilder()
    .put(ResourceAttributes.SERVICE_NAME, "my-service")
    .build();

SdkTracerProvider tracerProvider = SdkTracerProvider.builder()
    .setResource(resource)
    .addSpanProcessor(BatchSpanProcessor.builder(
        OtlpGrpcSpanExporter.builder()
            .setEndpoint("http://localhost:4317")
            .build()
    ).build())
    .build();

OpenTelemetry openTelemetry = OpenTelemetrySdk.builder()
    .setTracerProvider(tracerProvider)
    .build();

try (GrpcTransport transport = GrpcTransport.forConnectionString(connectionString)
        .withAuthProvider(CloudAuthHelper.getAuthProviderFromEnviron())
        .withTracer(OpenTelemetryTracer.fromOpenTelemetry(openTelemetry))
        .build();
     QueryClient queryClient = QueryClient.newClient(transport).build()) {
    // Use queryClient here
}
```

When using the JDBC driver, simply add the `enableOpenTelemetryTracer=true` parameter to the connection string — the driver will automatically pick up the global OTel provider:

```
jdbc:ydb://<host>:<port>/<database>?enableOpenTelemetryTracer=true
```

Python

Install additional dependencies `opentelemetry` and the OTLP exporter:

```
pip install ydb[opentelemetry]
pip install opentelemetry-exporter-otlp-proto-grpc
```

Call `enable_tracing()` after configuring the global `TracerProvider`:

```
from opentelemetry import trace
from opentelemetry.sdk.trace import TracerProvider
from opentelemetry.sdk.trace.export import BatchSpanProcessor
from opentelemetry.exporter.otlp.proto.grpc.trace_exporter import OTLPSpanExporter
from opentelemetry.sdk.resources import Resource

import ydb
from ydb.opentelemetry import enable_tracing

resource = Resource(attributes={"service.name": "my-service"})
provider = TracerProvider(resource=resource)
provider.add_span_processor(
    BatchSpanProcessor(OTLPSpanExporter(endpoint="http://localhost:4317"))
)
trace.set_tracer_provider(provider)

enable_tracing()

with ydb.Driver(endpoint="grpc://localhost:2136", database="/local") as driver:
    driver.wait(timeout=5)
    with ydb.QuerySessionPool(driver) as pool:
        pool.execute_with_retries("SELECT 1")

provider.shutdown()
```

C#

Add the NuGet package:

```
dotnet add package Ydb.Sdk.OpenTelemetry
```

Register the YDB instrumentation when configuring OpenTelemetry in your service:

```
services.AddOpenTelemetry()
    .WithTracing(builder => builder
        .AddYdb()
        .AddOtlpExporter());
```

JavaScript

Install `@ydbjs/telemetry` together with the OpenTelemetry Node SDK and OTLP exporter:

```
npm install @ydbjs/telemetry @opentelemetry/sdk-node @opentelemetry/exporter-trace-otlp-http
```

Initialize `NodeSDK` before creating the driver and call `register()` from `@ydbjs/telemetry`:

```
import { NodeSDK } from '@opentelemetry/sdk-node'
import { OTLPTraceExporter } from '@opentelemetry/exporter-trace-otlp-http'
import { Driver } from '@ydbjs/core'
import { query } from '@ydbjs/query'
import { register } from '@ydbjs/telemetry'

const sdk = new NodeSDK({
    serviceName: 'my-service',
    traceExporter: new OTLPTraceExporter({ url: 'http://localhost:4318/v1/traces' }),
})
sdk.start()

// Must be called BEFORE creating Driver — W3C propagation middleware
// trace context is set once during driver construction.
const instrumentation = register()

using driver = new Driver(process.env.YDB_CONNECTION_STRING)
await driver.ready()
await using sql = query(driver)
// ...

instrumentation.disable()
await sdk.shutdown()
```

Alternatively, via `--import` for auto-loading before application start:

```
node --import @opentelemetry/sdk-node/register --import @ydbjs/telemetry/register your-app.js
```

Rust

This functionality is not currently supported.

PHP

This functionality is not currently supported.

Enabling tracing in Jaeger

Below are code examples for enabling tracing in Jaeger in different YDB SDKs.

C++

This feature is not currently supported.

Go

Native SDK

```
package main

import (
    "context"
    "time"

    "github.com/opentracing/opentracing-go"
    jaegerConfig "github.com/uber/jaeger-client-go/config"

    "github.com/ydb-platform/ydb-go-sdk/v3"
    "github.com/ydb-platform/ydb-go-sdk/v3/trace"

    tracing "github.com/ydb-platform/ydb-go-sdk-opentracing"
)

const (
    tracerURL   = "localhost:5775"
    serviceName = "ydb-go-sdk"
)

func main() {
    tracer, closer, err := jaegerConfig.Configuration{
        ServiceName: serviceName,
        Sampler: &jaegerConfig.SamplerConfig{
            Type:  "const",
            Param: 1,
        },
        Reporter: &jaegerConfig.ReporterConfig{
            LogSpans:            true,
            BufferFlushInterval: 1 * time.Second,
            LocalAgentHostPort:  tracerURL,
        },
    }.NewTracer()
    if err != nil {
        panic(err)
    }

    defer closer.Close()

    // set global tracer of this application
    opentracing.SetGlobalTracer(tracer)

    span, ctx := opentracing.StartSpanFromContext(context.Background(), "client")
    defer span.Finish()

    db, err := ydb.Open(ctx,
        os.Getenv("YDB_CONNECTION_STRING"),
        tracing.WithTraces(tracing.WithDetails(trace.DetailsAll)),
    )
    if err != nil {
        panic(err)
    }
    defer db.Close(ctx)
    ...
}
```

database/sql

```go
package main

import (
    "context"
    "database/sql"
    "time"

    "github.com/opentracing/opentracing-go"
    jaegerConfig "github.com/uber/jaeger-client-go/config"

    "github.com/ydb-platform/ydb-go-sdk/v3"
    "github.com/ydb-platform/ydb-go-sdk/v3/trace"

    tracing "github.com/ydb-platform/ydb-go-sdk-opentracing"
)

const (
    tracerURL   = "localhost:5775"
    serviceName = "ydb-go-sdk"
)

func main() {
    tracer, closer, err := jaegerConfig.Configuration{
        ServiceName: serviceName,
            Sampler: &jaegerConfig.SamplerConfig{
            Type:  "const",
            Param: 1,
        },
        Reporter: &jaegerConfig.ReporterConfig{
            LogSpans:            true,
            BufferFlushInterval: 1 * time.Second,
            LocalAgentHostPort:  tracerURL,
        },
    }.NewTracer()
    if err != nil {
        panic(err)
    }

    defer closer.Close()

    // set global tracer of this application
    opentracing.SetGlobalTracer(tracer)

    span, ctx := opentracing.StartSpanFromContext(context.Background(), "client")
    defer span.Finish()

    nativeDriver, err := ydb.Open(ctx,
        os.Getenv("YDB_CONNECTION_STRING"),
        tracing.WithTraces(tracing.WithDetails(trace.DetailsAll)),
    )
    if err != nil {
        panic(err)
    }
    defer nativeDriver.Close(ctx)

    connector, err := ydb.Connector(nativeDriver)
    if err != nil {
        panic(err)
    }

    db := sql.OpenDB(connector)
    defer db.Close()
    ...
}
```

Comparison of SDK features

This section allows you to compare the capabilities of the YDB SDK, which are implemented for different programming languages.

Common features

Feature	C++	Python	Go	Java	NodeJS	C#	Rust	PHP
support connection string 'grpc[s]://endpoint:port/database'	+	+	+	+	+	–	+	–
SSL/TLS support (system certificates)	+	+	+	+	+	+	+	+
SSL/TLS support (custom certificates)	+	+	+	+	+	+	+	+
Configure/enable GRPC KeepAlive (keeping the connection alive in the background)	+	+	+	+	–	–	+	+
Regular SLO testing on the latest code version	+	+	+	+	–	+	+	–
Issue templates on GitHub	–	+	+	–	+	+	+	+

Client-side balancing

Feature	C++	Python	Go	Java	NodeJS	C#	Rust	PHP
Load balancer initialization through Discovery/ListEndpoints	+	+	+	+	+	+	+	+
Disable client-side load balancing (all requests to the initial Endpoint)	+	+	+	–	+	+	+	+
Background Discovery/ListEndpoints (by default, once a minute)	+	+	+	+	+	+	+	+
Support for multiple IP addresses in the initial Endpoint DNS record, Endpoint DNS record, some of which may not be available (DNS load balancing)	+	+	+	–	+	–	+	+
Connection pessimization on transport errors	+	+	+	+	+	+	+	–
Forced Discovery/ListEndpoints if more than half of the nodes are pessimized	+	+	+	+	–	+	+	–
Automatic detection of the nearest DC/availability zone by TCP pings	–	+	+	+	–	+	+	–
Automatic detection of the nearest DC/availability zone by Discovery/ListEndpoints response	+	+	+	+	–	–	–	–
Uniform random selection of nodes (default)	+	+	+	+	+	+	+	+
Load balancing across all nodes of all DCs (default)	+	+	+	+	+	+	+	+
Load balancing across all nodes of a particular DC/availability zone (for example, “a”, “vla”)	+	+	+	+	–	–	–	–
Load balancing across all nodes of all local DCs	+	+	+	+	–	–	–	–
Route all requests into the initial endpoint instead of client-side load balancing (for serverless usage)	+	+	+	+	+	+	+	+

Credentials providers

Feature	C++	Python	Go	Java	NodeJS	C#	Rust	PHP
Anonymous (default)	+	+	+	+	+	+	+	+
Static (user - password)	+	+	+	+	+	+	+	+
Token: IAM, Access token	+	+	+	+	+	+	+	+
Service account (Yandex.Cloud specific)	+	+	+	+	+	+	+	+
Metadata (Yandex.Cloud specific)	+	+	+	+	+	+	+	+

Support for YDB data types

Feature	C++	Python	Go	Java	NodeJS	C#	Rust	PHP

Int/Uint(8,16,32,64)	+	+	+	+	+	+	+	+
Float, Double	+	+	+	+	+	+	+	+
Bool	+	+	+	+	+	+	+	+
String, Bytes	+	+	+	+	+	+	+	+
Utf8, Text	+	+	+	+	+	+	+	+
NULL, Optional, Void	+	+	+	+	+	–	+	–
Struct	+	+	+	+	+	+	+	+
List	+	+	+	+	+	–	+	+
Set	–	+	+	–	–	–	–	–
Tuple	+	+	+	+	+	+	+	+
Variant<Struct>,Variant<Tuple>	+	+	+	+	+	–	–	–
Date, DateTime, Timestamp, Interval	+	+	+	+	+	+	+	–
TzDate, TzDateTime, TzTimestamp	+	+	+	+	+	–	–	–
DyNumber	+	+	+	+	+	–	–	–
Decimal (120 bits)	+	+	+	+	+	+	–	+
Json, JsonDocument, Yson	+	+	+	+	+	+	+	–
Wide date types (Date32, Datetime64, Timestamp64, Interval64)	+	+	+	+	–	+	+	–

YDB gRPC services clients

Discovery

Feature	C++	Python	Go	Java	NodeJS	C#	Rust	PHP
ListEndpoints	+	–	+	–	+	–	–	+
WhoAmI	+	–	+	–	+	–	–	+

Query

Feature	C++	Python	Go	Java	NodeJS	C#	Rust	PHP
Session pool	+	+	+	+	+	+	+	–
Limit the number of concurrent sessions on the client	+	+	+	+	–	+	+	–
Minimum number of sessions in the pool	+	–	+	+	–	+	+	–
Warm up the pool to the specified number of sessions when the pool is created	–	–	+	–	–	–	+	–
Background session attach stream used for clear pool from bad sessions	+	+	+	+	–	+	+	–
Retryer on the session pool (a repeat object is a session)	+	+	+	+	–	+	+	–
Retryer on the session pool (a repeat object is a transaction)	–	+	+	–	–	–	+	–
Support for server-side load balancing of sessions (a CreateSession request must contain the 'session-balancer' value in the 'x-ydb-client-capabilities' metadata header)	+	–	+	+	–	+	+	–
Transactions with tables and topics	+	+	+	–	+	–	+	–
* CreateSession	+	+	+	+	+	+	+	–
* DeleteSession	–	+	+	+	+	+	+	–
* AttachSession	+	+	+	+	+	+	+	–
* CommitTransaction	+	+	+	+	+	+	+	–

Languages and APIs

- ADO.NET - .NET Access to YDB
- JDBC driver for YDB
- YDB Model Context Protocol Server
- Generate code from YQL (sqlc-ydb)

ADO.NET - .NET Access to YDB

`Ydb.Sdk` is an ADO.NET Data Provider for YDB. It allows programs written in C#, Visual Basic, and F# to access the YDB database server. It is implemented in 100% C# code, is free, and is open source.

Documentation

- Getting Started with ADO.NET
- Installation ADO.NET
- Basic Usage with ADO.NET
- ADO.NET Connection Parameters
- ADO.NET Supported Types and Their Mappings
- Connection ADO.NET to Yandex Cloud
- Using Dapper

Getting Started with ADO.NET

The best way to use `Ydb.Sdk` is to install its NuGet package.

`Ydb.Sdk.Ado` aims to be fully ADO.NET-compatible; its API should feel almost identical to other .NET database drivers.

Here's a basic code snippet to get you started:

```
await using var ydbDataSource = new YdbDataSource("Host=localhost;Port=2136;Database=/local;MaxSessionPool=5
0");
await using var ydbConnection = await ydbDataSource.OpenConnectionAsync();

var ydbCommand = ydbConnection.CreateCommand();
ydbCommand.CommandText = """
                         SELECT series_id, season_id, episode_id, air_date, title
                         FROM episodes
                         WHERE series_id = @series_id AND season_id > @season_id
                         ORDER BY series_id, season_id, episode_id
                         LIMIT @limit_size;
                         """;
ydbCommand.Parameters.Add(new YdbParameter("series_id", DbType.UInt64, 1U));
ydbCommand.Parameters.Add(new YdbParameter("season_id", DbType.UInt64, 1U));
ydbCommand.Parameters.Add(new YdbParameter("limit_size", DbType.UInt64, 3U));

var ydbDataReader = await ydbCommand.ExecuteReaderAsync();

_logger.LogInformation("Selected rows:");
while (await ydbDataReader.ReadAsync())
{
    _logger.LogInformation(
        "series_id: {series_id}, season_id: {season_id}, episode_id: {episode_id}, air_date: {air_date}, titl
e: {title}",
        ydbDataReader.GetUint64(0), ydbDataReader.GetUint64(1), ydbDataReader.GetUint64(2),
        ydbDataReader.GetDateTime(3), ydbDataReader.GetString(4));
}
```

You can find more info about the ADO.NET API in the MSDN docs or in many tutorials on the Internet.

Installation ADO.NET

Official releases of `Ydb.Sdk` are always available on nuget.org. This is the recommended way to use `Ydb.Sdk`.

```
dotnet add package Ydb.Sdk
```

Basic Usage with ADO.NET

This article covers core ADO.NET usage scenarios for YDB, including database connections, query execution, and result processing. See the main documentation for additional details.

Data Source

The entry point for any database operation is DbDataSource.

You can create a YdbDataSource in following ways.

1. **Without parameters**:

   The following code creates a data source with default settings:

   ```
   await using var ydbDataSource = new YdbDataSource();
   ```

   In this case, the connection URL is `grpc://localhost:2136/local` with anonymous authentication.

2. **Using a connection string**:

   Create a data source with an ADO.NET connection string

   ```
   await using var ydbDataSource = new YdbDataSource(
       "Host=database-sample-grpc;Port=2135;Database=/root/database-sample");
   ```

   The data source will use URL: `grpc://database-sample-grpc:2135/root/database-sample.` The supported settings are described on the connection parameters page.

3. **Using a YdbConnectionStringBuilder**:

   ```
   var ydbConnectionBuilder = new YdbConnectionStringBuilder
   {
       Host = "localhost",
       Port = 2136,
       Database = "/local",
       UseTls = false
   };

   await using var ydbDataSource = new YdbDataSource(ydbConnectionBuilder);
   ```

   YdbConnectionStringBuilder also supports additional options beyond the connection string, such as logging and advanced authentication.

Connections

A connection to YDB is established via `YdbConnection`. You obtain connections from `YdbDataSource` using the following methods:

1. **YdbDataSource.OpenConnectionAsync**:

   Opens a connection to YDB using the parameters set on YdbDataSource (see the YDB Data Source section).

   ```
   await using var ydbConnection = await ydbDataSource.OpenConnectionAsync();
   ```

   Recommended for long-running read queries.

2. **YdbDataSource.OpenRetryableConnectionAsync**:

   Opens a connection with automatic operation retries that follow the YDB Retry Policy (see the retries section).

   ```
   await using var ydbConnection = await ydbDataSource.OpenRetryableConnectionAsync();
   ```

   Mode specifics:

   - Interactive transactions are not supported.
   - Commands (YdbCommand) created from this connection automatically retry single operations on transient errors.
   - Attempting to use a transaction will throw an exception (see the transactions section).

   > **Warning**
   >
   > Be careful with “long” reads in this mode: they may lead to Out Of Memory (OOM), because the entire result set is read into memory to obtain final statuses from the server.

3. **Not recommended**: CreateConnection/constructor:

   Using `YdbDataSource.CreateConnection` and the `YdbConnection` constructor (legacy ADO.NET API) is not recommended. If you still need it, open the connection manually:

   - With a connection string:

   ```
   await using var ydbConnection = new YdbConnection(
       "Host=database-sample-grpc;Port=2135;Database=/root/database-sample");
   await ydbConnection.OpenAsync();
   ```

   - With `YdbConnectionStringBuilder`:

```
var ydbConnectionBuilder = new YdbConnectionStringBuilder
{
    Host = "server",
    Port = 2135,
    Database = "/ru-prestable/my-table",
    UseTls = true
};
await using var ydbConnection = new YdbConnection(ydbConnectionBuilder);
await ydbConnection.OpenAsync();
```

- With `YdbDataSource.CreateConnection`:

```
await using var ydbConnection = ydbDataSource.CreateConnection();
await ydbConnection.OpenAsync();
```

Pooling

Opening a new connection to YDB is an expensive operation, so the provider uses a connection pool. When a connection object is disposed or closed, it is not actually closed — instead, it's returned to the pool managed by Ydb.Sdk.Ado. On subsequent requests, a pooled connection is reused. This makes open/close operations fast: open and close connections as needed, and avoid keeping them open unnecessarily for a long time.

> **Note**
>
> Pooling is in effect for connections opened via YdbDataSource (e.g., OpenConnectionAsync/OpenRetryableConnectionAsync), as well as for connections created manually with the YdbConnection constructor followed by OpenAsync().

> **Note**
>
> How it works under the hood: for application code, a "connection" is logical. Under the hood, operations are RPC calls over a small pool of gRPC/HTTP/2 channels. The provider also manages a table session pool. These details are transparent to the user and are controlled by pooling parameters (see Pooling settings: connection-parameters.md#pooling).

To clear the pool and close network channels to YDB nodes:

- `YdbDataSource.DisposeAsync()`: Disposes the data source. Closes all associated pools and network channels tied to the `ConnectionString`.
- `YdbConnection.ClearPool`: Immediately closes all idle connections in the pool associated with the specified connection's `ConnectionString`. Active connections are closed when returned to the pool.

```
await YdbConnection.ClearPool(ydbConnection);
```

- `YdbConnection.ClearAllPools()`: Immediately closes all idle connections in all pools. Active connections are closed when returned to the pool.

```
YdbConnection.ClearAllPools();
```

Basic SQL Execution

Once you have a `YdbConnection`, an `YdbCommand` can be used to execute SQL against it:

```
await using var ydbCommand = new YdbCommand("SELECT some_field FROM some_table", ydbConnection);
await using var ydbDataReader = await ydbCommand.ExecuteReaderAsync();

while (await ydbDataReader.ReadAsync())
{
    Console.WriteLine(ydbDataReader.GetString(0));
}
```

Other Execution Methods

Above, SQL is executed via ExecuteReaderAsync. There are various ways to execute a command, depending on the results you expect from it:

1. ExecuteNonQueryAsync: executes SQL that doesn't return any results, typically `INSERT`, `UPDATE`, or `DELETE` statements.

   > **Warning**
   >
   > YDB does not return the number of rows affected.

2. ExecuteScalarAsync: executes SQL that returns a single scalar value.
3. ExecuteReaderAsync: executes SQL that returns a full result set. Returns a `YdbDataReader`, which can be used to access the result set (as in the example above).

For example, to execute a simple SQL `INSERT` that does not return anything, you can use `ExecuteNonQueryAsync` as follows:

```
await using var ydbCommand = new YdbCommand("INSERT INTO some_table (some_field) VALUES ('Hello YDB!'u)", ydb
Connection);
await ydbCommand.ExecuteNonQueryAsync();
```

Parameters

When sending data values to the database, always consider using parameters rather than including the values in the SQL, as shown in the following example:

```
await using var ydbConnection = await ydbDataSource.OpenConnectionAsync();

var ydbCommand = ydbConnection.CreateCommand();
ydbCommand.CommandText = """
                         SELECT series_id, season_id, episode_id, air_date, title
                         FROM episodes WHERE series_id = $series_id AND season_id > $season_id
                         ORDER BY series_id, season_id, episode_id
                         LIMIT $limit_size;
                         """;
ydbCommand.Parameters.Add(new YdbParameter("$series_id", DbType.UInt64, 1U));
ydbCommand.Parameters.Add(new YdbParameter("$season_id", DbType.UInt64, 1U));
ydbCommand.Parameters.Add(new YdbParameter("$limit_size", DbType.UInt64, 3U));

var ydbDataReader = await ydbCommand.ExecuteReaderAsync();
```

SQL query parameters can be set using the `YdbParameter` class.

In this example, the parameters `$series_id`, `$season_id`, and `$limit_size` are declared within the SQL query and then added to the command using `YdbParameter` objects.

Alternative Parameter Style with `@` Prefix

Parameters can also be specified using the `@` prefix. In this case, there is no need to declare variables within the query itself. The query will look like this:

```
ydbCommand.CommandText = """
                         SELECT series_id, season_id, episode_id, air_date, title
                         FROM episodes
                         WHERE series_id = @series_id AND season_id > @season_id
                         ORDER BY series_id, season_id, episode_id
                         LIMIT @limit_size;
                         """;
ydbCommand.Parameters.Add(new YdbParameter("series_id", DbType.UInt64, 1U));
ydbCommand.Parameters.Add(new YdbParameter("season_id", DbType.UInt64, 1U));
ydbCommand.Parameters.Add(new YdbParameter("limit_size", DbType.UInt64, 3U));
```

With ADO.NET, the query will be prepared for you so that the variables match YQL. The type of each parameter will be determined by YdbDbType, in its absence — by DbType, otherwise it is derived from .NET is the type of value.

Parameter Types

YDB has a strongly-typed type system: columns and parameters have a type, and types are usually not implicitly converted to other types. This means you have to think about which type you will be sending: trying to insert a string into an integer column (or vice versa) will fail.

For more information on supported types and their mappings, see this page.

Transactions

Interactive transactions and retries are a key part of working with YDB.

YdbDataSource provides helper methods that make it easier to run code in a transaction with automatic retries.

```
await ydbDataSource.ExecuteInTransactionAsync(async ydbConnection =>
{
    var count = (int)(await new YdbCommand(ydbConnection)
        { CommandText = $"SELECT count FROM {tableName} WHERE id = 1" }
        .ExecuteScalarAsync())!;

    await new YdbCommand(ydbConnection)
    {
        CommandText = $"UPDATE {tableName} SET count = @count + 1 WHERE id = 1",
        Parameters = { new YdbParameter { Value = count, ParameterName = "count" } }
    }.ExecuteNonQueryAsync();
},
new YdbRetryPolicyConfig { MaxAttempts = 5 });
```

Retries are performed according to YDB policies (see the retries section).

Transactions with YdbConnection

You can create a transaction in the standard ADO.NET way:

```
await using var connection = await dataSource.OpenConnectionAsync();
await using var transaction = await connection.BeginTransactionAsync();
// ... commands within the transaction ...
await transaction.CommitAsync();
```

Warning

See more about Transaction Lock Invalidation)

Note

This is acceptable and recommended for long reads. Use snapshot read-only transactions for consistent snapshots; they do not take write locks and minimize conflicts.

There are two signatures of this method with a single isolation level parameter:

- `BeginTransaction(TxMode txMode)`

  The `Ydb.Sdk.Services.Query.TxMode` is a YDB specific isolation level, you can read more about it here.
- `BeginTransaction(IsolationLevel isolationLevel)`

  The `System.Data.IsolationLevel` parameter from the standard ADO.NET. The following isolation levels are supported: `Serializable` and `Unspecified`. Both are equivalent to the `TxMode.SerializableRW`.

Calling `BeginTransaction()` without parameters opens a transaction with level the `TxMode.SerializableRW`.

YDB does not support nested or concurrent transactions. At any given moment, only one transaction per connection can be in progress, and starting a new transaction while another is already running throws an exception. Therefore, there is no need to pass the `YdbTransaction` object returned by `BeginTransaction()` to commands you execute. When a transaction is started, all subsequent commands are automatically included until a commit or rollback is made. To ensure maximum portability, however, it is best to set the transaction scope for your commands explicitly.

Retries

Retries are an important part of YDB's design. The ADO.NET provider offers a flexible retry policy tailored to YDB specifics.

Recommendations for choosing an approach:

- Single write operations (without interactive transactions): use `YdbDataSource.OpenRetryableConnectionAsync`.
- Transactional scenarios: use the `YdbDataSource.ExecuteInTransactionAsync` family.
- Executing code with automatic retries outside a transaction: use the `YdbDataSource.ExecuteAsync` family.
- Long read operations: use a regular `YdbConnection`. For consistent snapshots, use snapshot read-only transactions. Avoid retry connections for "long" reads to prevent excessive result buffering.

Passing policy settings

You can pass `YdbRetryPolicyConfig` into `OpenRetryableConnectionAsync`, `ExecuteInTransactionAsync`, and `ExecuteAsync`.

- Connection with retries:

```
await using var conn = await ydbDataSource.OpenRetryableConnectionAsync(
    new YdbRetryPolicyConfig { MaxAttempts = 5 });
```

- Transaction with retries:

```
await ydbDataSource.ExecuteInTransactionAsync(
    async conn => { /* your code */ },
    new YdbRetryPolicyConfig { MaxAttempts = 5 });
```

- Executing a code block with retries:

```
await ydbDataSource.ExecuteAsync(
    async conn => { /* your code */ },
    new YdbRetryPolicyConfig { MaxAttempts = 5 });
```

Параметр	Описание	Значение по умолчанию
MaxAttempts	Total number of attempts, including the initial one. A value of 1 disables retries entirely.	10
EnableRetryIdempotence	Enables retries for statuses with unknown execution outcome on the server. Use only for idempotent operations — otherwise the operation may be applied twice.	false
FastBackoffBaseMs	Base delay (ms) for fast retries: errors that typically resolve quickly (e.g., temporary unavailability, TLI — Transaction Locks Invalidated). Exponential backoff with jitter.	5
FastCapBackoffMs	Maximum delay (ms) for fast retries. Exponential backoff with jitter will not exceed this cap.	500
SlowBackoffBaseMs	Base delay (ms) for slow retries: overload, resource exhaustion, etc. Exponential backoff with jitter.	50
SlowCapBackoffMs	Maximum delay (ms) for slow retries. Exponential backoff with jitter will not exceed this cap.	5000

Custom retry policy

For edge cases, you can implement your own policy by implementing `Ydb.Sdk.Ado.Retry.IRetryPolicy`. The policy receives a `YdbException` and the current attempt number and must return whether to retry and with what delay.

> **Warning**
>
> If you choose this approach, be certain you understand what you're doing: you are opting out of well-tuned default settings.

Error Handling

> **Note**
>
> This section is relevant if you do not use the provider's built-in retries (see the retries section).

All exceptions related to database operations are subclasses of `YdbException`.

To safely handle errors that might occur during command execution, you can use a `try-catch` block. Here is an example:

```
try
{
    await command.ExecuteNonQueryAsync();
}
catch (YdbException e)
{
    Console.WriteLine($"Error executing command: {e}");
}
```

Properties of `YdbException`

The `YdbException` exception has the following properties, which can help you handle errors properly:

- `IsTransient` returns `true` if the error is temporary and can be resolved by retrying. For example, this might occur in cases of a transaction lock violation when the transaction fails to complete its commit.
- `IsTransientWhenIdempotent` returns `true` if the error is temporary and can be resolved by retrying the operation, provided that the database operation is idempotent.
- `StatusCode` contains the database error code, which is helpful for logging and detailed analysis of the issue.

> **Warning**
>
> Please note that ADO.NET does not automatically retry failed operations, and you must implement retry logic in your code.

Examples

Examples are provided on GitHub at link.

ADO.NET Connection Parameters

To connect to a database, the application provides a connection string that specifies parameters such as the host, user, password, and so on. Connection strings have the form `keyword1=value; keyword2=value;`. For more information, see the official doc page on connection strings.

All available connection parameters are defined as properties in the `YdbConnectionStringBuilder`.

Below are the connection string parameters that `Ydb.Sdk.Ado` supports.

Basic Connection

Parameter	Description	Default value
Host	Host of the YDB server.	localhost
Port	Port of the YDB server.	2136
Database	Database path.	/local
User	User name.	Not defined
Password	User password.	Not defined

Security and Encryption

Parameter	Description	Default value
UseTls	Determines whether to establish a secure connection using TLS (`grpcs`); when false, TLS is not used (`grpc`).	false
RootCertificate	Path to a trusted root/intermediate server certificate file (PEM). When set, `UseTls` is automatically set to true.	Not defined

Pooling

Parameter	Description	Default value
MinPoolSize	Minimum session pool size.	0
MaxPoolSize	Maximum session pool size.	100
SessionIdleTimeout	Time to wait (seconds) before closing idle sessions in the pool when the total number of sessions exceeds `MinPoolSize`.	300

Keepalive

Parameter	Description	Default value
ConnectTimeout	Time to wait (in seconds) when establishing a connection to the server. Must be greater than or equal to 0. Set 0 for infinite wait.	10
CreateSessionTimeout	Time to wait (in seconds) when creating a new session. Must be greater than or equal to 0. Set 0 for infinite wait.	5
KeepAlivePingDelay	Idle period (in seconds) after which a keepalive ping is sent when there is no traffic. This property is used together with the `KeepAlivePingTimeout` parameter to check whether the connection is broken. The value must be greater than or equal to 1 second. Set 0 to disable the keep alive connectivity check.	10
KeepAlivePingTimeout	Time to wait (in seconds) after sending a keepalive ping; if no messages are received during this time, the connection is closed. The time to wait must be greater than or equal to 1 second. Set 0 to disable the timeout for maintaining the connection in idle mode.	10

Performance

Параметр	Описание	Значение по умолчанию
EnableMultipleHttp2Connections	Determines whether to automatically scale HTTP/2 connections within a single gRPC channel to a single cluster node. This is rarely required, but can improve performance in scenarios with high load on a single node. When false, a single HTTP/2 connection per node is used.	false
MaxSendMessageSize	Maximum size of outgoing messages in bytes. Note: a 64 MB limit applies on the server; larger messages are rejected with the `ResourceExhausted` error.	67108864 (64 MB)
MaxReceiveMessageSize	Maximum size of incoming messages, bytes.	67108864 (64 MB)
DisableServerBalancer	Determines whether to disable session balancing on the server side; when false, balancing is enabled.	false

Parameters useful for Serverless applications

Параметр	Описание	Значение по умолчанию
DisableDiscovery	Determines whether to disable automatic node discovery and use a direct gRPC connection to the address from the connection string; when false, node discovery (discovery) is performed for client-side load balancing.	false
EnableImplicitSession	Determines whether implicit session management is enabled: the server creates and deletes sessions for each operation; on the client, a session pool is not used. **In this mode, interactive client transactions are not supported.**	false

Connection Builder Parameters

There are also additional parameters that do not participate in forming the connection string. These can only be specified using `YdbConnectionStringBuilder`:

Parameter	Description	Default value
`LoggerFactory`	This parameter accepts an instance that implements the ILoggerFactory interface. The `ILoggerFactory` is a standard interface for logging factories in .NET. It is possible to use popular logging frameworks such as NLog, serilog, log4net	`NullLoggerFactory.Instance`
`CredentialsProvider`	An authentication provider that implements the `Ydb.Sdk.Auth.ICredentialsProvider`. Standard ways for authentication: 1) `Ydb.Sdk.Auth.TokenProvider`. Token authentication for OAuth-like tokens. 2) For Yandex Cloud specific authentication methods, consider using **ydb-dotnet-yc**	`Anonymous`
`ServerCertificates`	Specifies custom server certificates used for TLS/SSL validation. This is useful when working with cloud providers (e.g., Yandex Cloud) that use custom root or intermediate certificates not trusted by default	Not defined

ADO.NET Supported Types and Their Mappings

The following lists the built-in mappings for reading and writing CLR types to YDB types.

Type Mapping Table for Reading

The following shows the mappings used when reading values.

- These are the return types when using `YdbCommand.ExecuteScalarAsync()`, `YdbDataReader.GetValue()`, and similar methods.
- You can read as other types by calling `YdbDataReader.GetFieldValue<T>()` and also `YdbDataReader.GetInt32()` / `YdbDataReader.GetInt64()` to get the raw value.

YDB тип	.NET тип	Non-default .NET типы
Bool	bool	
Int8	sbyte	
Int16	short	
Int32	int	
Int64	long	
Uint8	byte	
Uint16	ushort	
Uint32	uint	
Uint64	ulong	
Float	float	
Double	double	
Decimal (precision, scale)	decimal (см. раздел Decimal)	
Bytes (синоним `String`)	byte[]	
Text (синоним `Utf8`)	string	
Json	string	
JsonDocument	string	
Yson	byte[]	
Uuid	Guid	
Date	DateTime	DateOnly
Date32	DateTime	DateOnly, int (`GetInt32()` — raw value)
Datetime	DateTime	DateOnly
Datetime64	DateTime	DateOnly, long (`GetInt64()` — raw value)
Timestamp	DateTime	DateOnly
Timestamp64	DateTime	DateOnly, long (`GetInt64()` — raw value)
Interval	TimeSpan	long (`GetInt64()` — raw value)
Interval64	TimeSpan	long (`GetInt64()` — raw value)

Decimal

`Decimal (Precision, Scale)` is a parameterized data type in YDB that allows you to explicitly specify:

- `Precision` — the total number of significant digits;
- `Scale` — the number of digits after the decimal point.

For more details, see the documentation.

By default, the Decimal(22, 9) type is used. If you need to set different values for `Precision` and `Scale`, you can do this in your code.

The example below demonstrates how to store the value 1.5 in the database with the Decimal type and parameters Precision = 5 and Scale = 3.

```
await new YdbCommand(ydbConnection)
{
    CommandText = $"INSERT INTO {tableName}(Id, Decimal) VALUES (1, @Decimal);",
    Parameters = new YdbParameter { Name = "Decimal", Value = 1.5m, Precision = 5, Scale = 3 }
}.ExecuteNonQueryAsync();
```

Type Mapping Table for Writing

There are three rules that determine the YDB type sent for a parameter:

1. If the parameter's `YdbDbType` is set, it is used.
2. If the parameter's `DbType` is set, it is used.
3. If none of the above is set, the backend type will be inferred from the CLR value type.

YDB type	.NET type	Non-default .NET types	YdbDbType	DbType
Bool	bool		Bool	Boolean
Int8	sbyte		Int8	SByte
Int16	short	sbyte, byte	Int16	Int16
Int32	int	sbyte, byte, short, ushort	Int32	Int32
Int64	long	sbyte, byte, short, ushort, int, uint	Int64	Int64
Uint8	byte		Uint8	Byte
Uint16	ushort	byte	Uint16	UInt16
Uint32	uint	byte, ushort	Uint32	UInt32
Uint64	ulong	byte, ushort, uint	Uint64	UInt64
Float	float		Float	Single
Double	double	float	Double	Double
Decimal (precision, scale)	decimal		Decimal	Decimal, Currency
Bytes (synonym of `String`)	byte[]		Bytes	Binary
Text (synonym of `Utf8`)	string		Text	String, AnsiString, AnsiStringFixedLength, StringFixedLength
Json	string		Json	
JsonDocument	string		JsonDocument	
Yson	byte[]		Yson	
Uuid	Guid		Uuid	Guid
Date	DateOnly	DateTime	Date	Date
Date32		DateTime, DateOnly, int (raw value)	Date32	
Datetime		DateTime, DateOnly	Datetime	Datetime
Datetime64		DateTime, long (raw value)	Datetime64	
Timestamp	DateTime		Timestamp	DateTime2
Timestamp64		DateTime, long (raw value)	Timestamp64	
Interval	TimeSpan	long (raw value)	Interval	
Interval64		TimeSpan, long (raw value)	Interval64	
List	T[], List	T[], List	List | YdbDbType	

Note

When using List, specify the type as a bitwise OR of YdbDbType.List and the element type. For example, to specify the YdbDbType for List, use `YdbDbType.List | YdbDbType.Int32`.

Connection ADO.NET to Yandex Cloud

Installation

To use Yandex Cloud authentication in your .NET application, install the `Ydb.Sdk.Yc.Auth` NuGet package:

```
dotnet add package Ydb.Sdk.Yc.Auth
```

This package provides the necessary tools for authenticating with Yandex Cloud services.

Authentication

Supported Yandex.Cloud authentication methods:

- `Ydb.Sdk.Yc.ServiceAccountProvider`. Service account authentication, sample usage:

  ```
  var saProvider = new ServiceAccountProvider(
      saFilePath: file, // Path to file with service account JSON info
      loggerFactory: loggerFactory
  );
  ```

- `Ydb.Sdk.Yc.MetadataProvider`. Metadata service authentication, works inside Yandex Cloud VMs and Cloud Functions. Sample usage:

  ```
  var metadataProvider = new MetadataProvider(loggerFactory: loggerFactory);
  ```

Certificates

The library includes default Yandex Cloud server certificates, which are required for connectivity with dedicated YDB databases:

```
var certs = Ydb.Sdk.Yc.YcCerts.GetYcServerCertificates();
```

How to Connect with ADO.NET

To establish a secure connection to YDB using ADO.NET, configure `YdbConnectionStringBuilder` with the required authentication and TLS settings. Below is a detailed example:

```
var builder = new YdbConnectionStringBuilder
{
    // More settings ...
    UseTls = true,
    Port = 2135,
    CredentialsProvider = saProvider, // For service account
    ServerCertificates = YcCerts.GetYcServerCertificates() // custom certificates Yandex Cloud
};
```

Example

ADO.NET connect to Yandex Cloud

JDBC driver for YDB

The JDBC driver for YDB provides database connectivity for applications written in Java or other programming languages running on JVM, like Kotlin, Scala, etc.

Download

Download the JDBC driver for YDB from the latest releases page on GitHub.

Documentation

- Quick start with JDBC driver
- Using the JDBC driver with Maven
- Authentication modes
- JDBC driver properties
- Building the JDBC driver for YDB

Quick start with JDBC driver

1. Download the JDBC driver for YDB.
2. Copy the `.jar` file to the directory specified in the `CLASSPATH` environment variable or load the `.jar` file in your IDE.
3. Connect to YDB. JDBC URL examples:
   - Local Docker container with anonymous authentication and without TLS:
     `jdbc:ydb:grpc://localhost:2136/local`
   - Remote self-hosted cluster:
     `jdbc:ydb:grpcs://<host>:2135/Root/<testdb>?secureConnectionCertificate=~/<myca>.cer`
   - A cloud database instance with a token:
     `jdbc:ydb:grpcs://<host>:2135/<path/to/database>?tokenFile=~/my_token`
   - A cloud database instance with a service account:
     `jdbc:ydb:grpcs://<host>:2135/<path/to/database>?saKeyFile=~/sa_key.json`
4. Execute queries, for example, YdbDriverExampleTest.java.

Using the JDBC driver with Maven

The recommended way to use the YDB JDBC driver in a project is to include it as a Maven dependency. Specify the YDB JDBC driver in the `dependencies` section of `pom.xml`:

```
<dependencies>
    <dependency>
        <groupId>tech.ydb.jdbc</groupId>
        <artifactId>ydb-jdbc-driver</artifactId>
        <version><!-- actual version --></version>
    </dependency>
</dependencies>
```

Authentication modes

The JDBC Driver for YDB supports the following authentication modes:

- **Anonymous** is used when a username and password are not specified and no other authentication properties are configured. No authentication credentials are provided.
- **Static credentials** are used when a username and password are specified.
- **Access token** is used when the `token` or `tokenFile` property is configured. This authentication method requires a YDB authentication token, which can be obtained by executing the following YDB CLI command: `ydb auth get-token`.
- **Metadata** is used when the `useMetadata` property is set to `true`. This method extracts the authentication data from the metadata of a virtual machine, serverless container, or serverless function running in a cloud environment.
- **Service Account Key** is used when the `saFile` property is configured. This method extracts the service account key from a file and uses it for authentication.

JDBC driver properties

The JDBC driver for YDB supports the following configuration properties, which can be specified in the JDBC URL or passed via additional properties:

- `saKeyFile` — a path to the service account key file for authentication.
- `iamEndpoint` — custom IAM endpoint for authentication using a service account key.
- `token` — token value for authentication.
- `tokenFile` — a path to the file with token value for authentication.
- `useMetadata` — indicates whether to use metadata authentication. Valid values are:
  - `true` — use metadata authentication.
  - `false` — do not use metadata authentication.

  Default value: `false`.
- `metadataURL` — custom metadata endpoint.
- `localDatacenter` — the name of the data center local to the application being connected.
- `secureConnectionCertificate` — a path to the custom CA certificate file for TLS connections.

> **Note**
>
> The values of the `saKeyFile`, `tokenFile`, or `secureConnectionCertificate` properties can be either absolute paths from the file system root or relative paths from the user's home directory. Examples:
>
> - `saKeyFile=~/mysakey1.json`
> - `tokenFile=/opt/secret/token-file`
> - `secureConnectionCertificate=/etc/ssl/cacert.cer`

JDBC URL examples

- Local Docker container with anonymous authentication and without TLS:
  `jdbc:ydb:grpc://localhost:2136/local`
- Remote self-hosted cluster:
  `jdbc:ydb:grpcs://<host>:2135/Root/<testdb>?secureConnectionCertificate=~/<myca>.cer`
- A cloud database instance with a token:
  `jdbc:ydb:grpcs://<host>:2135/<path/to/database>?tokenFile=~/my_token`
- A cloud database instance with a service account:
  `jdbc:ydb:grpcs://<host>:2135/<path/to/database>?saKeyFile=~/sa_key.json`

Building the JDBC driver for YDB

To execute all tests in the project, run the `mvn test` command.

By default, all tests are run using a local YDB instance in Docker (if the host has Docker or Docker Machine installed).

To disable these tests, run: `mvn test -DYDB_DISABLE_INTEGRATION_TESTS=true`

YDB Model Context Protocol Server

YDB Model Context Protocol (MCP) server allows you to work with YDB databases from any Large Language Model (LLM) that supports MCP using any of the MCP clients. This integration enables AI-powered database operations and natural language interactions with your YDB instances.

Getting Started

Prerequisites

1. Install an MCP client that supports MCP tools (most do). The configuration examples below use a common format supported by several popular MCP clients (Claude Desktop, Cursor, etc.), but you may need to adjust the format to meet your client's requirements.
2. The YDB MCP server is a Python application that is typically co-hosted with the MCP client. There are several options for installing and running the YDB MCP server explained below, but all of them require a pre-installed Python 3.10+ environment.

Anonymous Authentication

uvx

uvx allows you to run Python applications without explicitly installing them.

Configure YDB MCP in your MCP client settings:

```
{
  "mcpServers": {
    "ydb": {
      "command": "uvx",
      "args": [
        "ydb-mcp",
        "--ydb-endpoint", "grpc://localhost:2136/local"
      ]
    }
  }
}
```

pipx

pipx allows you to run applications from PyPI without explicit installation (pipx itself must be installed first).

Configure YDB MCP in your MCP client settings:

```
{
  "mcpServers": {
    "ydb": {
      "command": "pipx",
      "args": [
        "run", "ydb-mcp",
        "--ydb-endpoint", "grpc://localhost:2136/local"
      ]
    }
  }
}
```

pip

Optionally, create and activate a Python virtual environment. Install YDB MCP using pip:

```
pip install ydb-mcp
```

Configure YDB MCP in your MCP client settings:

```
{
  "mcpServers": {
    "ydb": {
      "command": "python3",
      "args": [
        "-m", "ydb_mcp",
        "--ydb-endpoint", "grpc://localhost:2136/local"
      ]
    }
  }
}
```

Login-Password Authentication

uvx

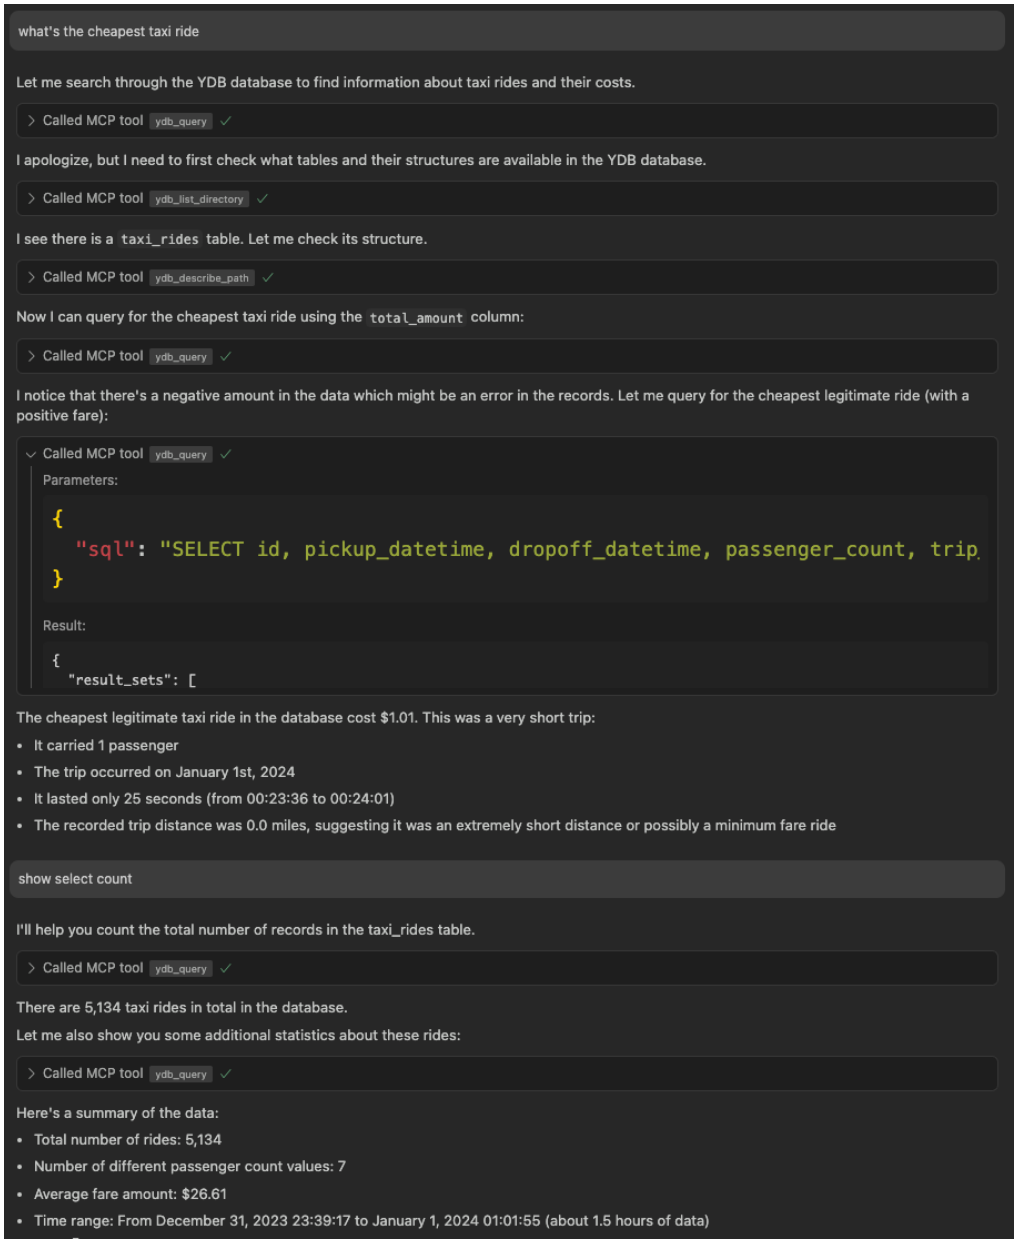
Configure login/password authentication with `uvx`:

```
{
  "mcpServers": {
    "ydb": {
      "command": "uvx",
      "args": [
        "ydb-mcp",
        "--ydb-endpoint", "grpc://localhost:2136/local",
        "--ydb-auth-mode", "login-password",
        "--ydb-login", "<your-username>",
        "--ydb-password", "<your-password>"
      ]
    }
  }
}
```

pipx

Configure login/password authentication with `pipx`:

```
{
  "mcpServers": {
    "ydb": {
      "command": "pipx",
      "args": [
        "run", "ydb-mcp",
        "--ydb-endpoint", "grpc://localhost:2136/local",
        "--ydb-auth-mode", "login-password",
        "--ydb-login", "<your-username>",
        "--ydb-password", "<your-password>"
      ]
    }
  }
}
```



pip

Configure login/password authentication with `pip`-installed YDB MCP:

```
{
  "mcpServers": {
    "ydb": {
      "command": "python3",
      "args": [
        "-m", "ydb_mcp",
        "--ydb-endpoint", "grpc://localhost:2136/local",
        "--ydb-auth-mode", "login-password",
        "--ydb-login", "<your-username>",
        "--ydb-password", "<your-password>"
      ]
    }
  }
}
```

Run Queries

Ask your LLM questions regarding the data stored in YDB using the MCP client configured above. The language model will see the tools available to it via MCP and will use them to execute YQL queries and other YDB API calls. An example of how it might look:

Available Tools

YDB MCP provides the following tools for interacting with YDB databases:

- `ydb_query`: Run a SQL query against a YDB database
  - Parameters:
    - `sql`: SQL query string to execute
- `ydb_query_with_params`: Run a parameterized SQL query with JSON parameters
  - Parameters:
    - `sql`: SQL query string with parameters
    - `params`: JSON string containing parameter values
- `ydb_list_directory`: List directory contents in YDB
  - Parameters:
    - `path`: YDB directory path to list
- `ydb_describe_path`: Get detailed information about a scheme object (table, directory, etc) located at the specified YDB path
  - Parameters:
    - `path`: YDB path to describe
- `ydb_status`: Get the current status of the YDB connection

Command-line arguments and environment variables

The following table describes the command-line arguments and environment variables for the YDB MCP server:

Arguments	Environment variable	Default	Description
`--ydb-endpoint`	`YDB_ENDPOINT`	—	YDB endpoint consisting of protocol, hostname, port, and database name
`--ydb-login`	`YDB_LOGIN`	—	YDB login
`--ydb-password`	`YDB_PASSWORD`	—	YDB password

`--ydb-auth-mode`	`YDB_AUTH_MODE`	`anonymous`	YDB authentication mode. Valid values: `anonymous`, `login-password`
`--log-level`	—	`INFO`	Logging level. Valid values: `DEBUG`, `INFO`, `WARNING`, `ERROR`, `CRITICAL`

Note

Command-line arguments override the corresponding environment variables.

Learn More

For more information visit the YDB MCP GitHub repository.

YDB AI skills (ydb-ai-skills)

ydb-ai-skills is a set of skills for AI coding agents that assist when working with YDB: writing YQL queries, designing the data schema, and reviewing application code for correct use of the YDB SDK. Skills plug into your AI agent and activate automatically based on the request context.

> **Warning**
>
> The project is under active development. The set of skills and their content are expanding, so the composition and behavior may change. See the project repository for up-to-date information.

What's inside

Skill	Purpose
ydb-core	Baseline skill: YDB overview, connection, authentication, schema basics, CLI. Installed automatically.
ydb-table	Auditing and reviewing application code that uses the YDB SDK, schema design, writing YQL.

Supported agents

Skills are distributed in a universal format and installed into the corresponding agent's directory.

Agent	Project directory	Global directory
Claude Code	`.claude/skills/`	`~/.claude/skills/`
Cursor	`.cursor/skills/`	—
Windsurf	`.windsurf/skills/`	—
GitHub Copilot	`.github/skills/`	`~/.copilot/skills/`
Codex CLI	`.agents/skills/`	`~/.codex/skills/`
Roo Code	`.roo/skills/`	—
Gemini CLI	`.gemini/skills/`	`~/.gemini/skills/`
Amp	`.agents/skills/`	`~/.config/agents/skills/`
Kiro	`.kiro/skills/`	—
Trae	`.trae/skills/`	—
Generic	`.agents/skills/`	`~/.agents/skills/`

Installation

```
git clone https://github.com/ydb-platform/ydb-ai-skills.git
cd ydb-ai-skills

# Auto-detect agents in the current project
./install.sh --detect

# Install for a specific agent
./install.sh --agent=claude

# Install only ydb-table (ydb-core is added as the baseline skill)
./install.sh --agent=claude --skills=ydb-table

# Install only ydb-table without the baseline skill
./install.sh --agent=claude --skills=ydb-table --no-core

# Dry run — show what would be done without making changes
./install.sh --agent=claude --dry-run
```

Usage

No separate action is required to start: the agent connects the appropriate skill itself when the task concerns YDB. If the agent does not support auto-activation, specify the skill name (`ydb-core` or `ydb-table`) in the request explicitly.

Code review

The `ydb-table` skill checks application code for common mistakes when working with the YDB SDK and points to the violated rules. To run a review, point the agent at the file or the range of changes.

Local run with Ollama

You can use the skills with an agent running on a local model via Ollama, without calling the cloud API. The `ollama launch` command is available starting from Ollama v0.15.

```
# 1. Pull a local model (tool calling support and a large context are required)
ollama pull gpt-oss:20b

# 2. Run Claude Code on that model — the skills activate as usual
ollama launch claude --model gpt-oss:20b
```

For agentic workflows, a context length of at least 64,000 tokens is recommended (configured in Ollama).

Kafka API

YDB supports working with topics using the Kafka protocol version 3.4.0. It allows to integrate YDB with applications originally developed to work with Apache Kafka.

The Kafka API documentation contains the following sections:

- Authentication
- Usage examples
- Kafka Connect
- Constraints

Kafka API

YDB supports working with topics using the Kafka protocol version 3.4.0. It allows to integrate YDB with applications originally developed to work with Apache Kafka.

The Kafka API documentation contains the following sections:

- Authentication
- Usage examples
- Kafka Connect
- Constraints

Kafka API authentication

Enabling authentication

When you run a single-node local YDB cluster, anonymous authentication is used by default. It doesn't require a username and password.

To require authentication see Authentication.

Authentication is always enabled when using the Kafka API in Yandex Cloud.

How does authentication work in the Kafka API?

The Kafka API uses the `SASL_PLAINTEXT/PLAIN`, `SASL_SSL/PLAIN` and mTLS authentication mechanisms.

Auhentication using PLAIN or SCRAM-SHA-256

The following variables are required for authentication:

- `<user-name>` — the username. For information about user management, refer to the Authorization section.
- `<password>` — the user's password. For information about user management, refer to the Authorization section.
- `<database>` — the database path.

These parameters form the following variables, which you can use in the `sasl.jaas.config` Kafka client property:

- `<sasl.username> = <user-name>@<database>`
- `<sasl.password> = <password>`

> **Note**
>
> The `<sasl.username>` and `<sasl.password>` parameters are formed differently. See examples for details.

For authentication examples, see Kafka API usage examples.

Authentication using mTLS

To enable mTLS authentication, the following steps are required.

Server and client certificates creation

For each step below the examples of commands are given. Substitute *** with your values.

1. Create Certificate Authority (CA)

```
openssl genrsa -out ca-key.pem 4096
```

```
openssl req -new -x509 -days 3650 -key ca-key.pem -out ca-cert.pem -subj "/C=***/ST=***/L=***/O=***/CN=MyKafk
aRootCA"
```

2. Create server certificate

```
openssl genrsa -out server-key.pem 4096
```

In the next command put your host name instead of `serverhost.com`.

```
openssl req -new -key server-key.pem -out server-cert.csr -subj "/C=***/ST=***/L=***/O=***/CN=serverhost.com"
```

```
cat > server-ext.cnf << EOF
authorityKeyIdentifier=keyid,issuer
basicConstraints=CA:FALSE
keyUsage = digitalSignature, nonRepudiation, keyEncipherment, dataEncipherment
subjectAltName = DNS:serverhost.com
EOF
```

```
openssl x509 -req -in server-cert.csr -CA ca-cert.pem -CAkey ca-key.pem -CAcreateserial -out server-cert.pem
-days 365 -extfile server-ext.cnf
```

3. Create client certificate

```
openssl genrsa -out client-key.pem 4096
```

Substitute `clienthost.com` with hostname of your client.

```
openssl req -new -key client-key.pem -out client-cert.csr -subj "/C=***/ST=***/L=***/O=***/CN=clienthost.com"
```

```
cat > client-ext.cnf << EOF
authorityKeyIdentifier=keyid,issuer
basicConstraints=CA:FALSE
keyUsage = digitalSignature, nonRepudiation, keyEncipherment, dataEncipherment
subjectAltName = DNS:clienthost.com
EOF
```

```
openssl x509 -req -in client-cert.csr -CA ca-cert.pem -CAkey ca-key.pem -CAcreateserial -out client-cert.pem
-days 365 -extfile client-ext.cnf
```

4. Add created certificates to keystore and truststore

For server:

```
openssl pkcs12 -export -in server-cert.pem -inkey server-key.pem -out server.p12 -name kafka-server -CAfile c
a-cert.pem -caname root -password pass:changeit

keytool -importkeystore -deststorepass changeit -destkeystore server.keystore.jks -srckeystore server.p12 -sr
cstoretype PKCS12 -srcstorepass changeit -alias kafka-server

keytool -import -trustcacerts -alias ca -file ca-cert.pem -keystore server.truststore.jks -storepass changeit
-noprompt
```

For client:

```
openssl pkcs12 -export -in client-cert.pem -inkey client-key.pem -out client.p12 -name kafka-client -CAfile c
a-cert.pem -caname root -password pass:changeit

keytool -importkeystore -deststorepass changeit -destkeystore client.keystore.jks -srckeystore client.p12 -sr
cstoretype PKCS12 -srcstorepass changeit -alias kafka-client

keytool -import -trustcacerts -alias ca -file ca-cert.pem -keystore client.truststore.jks -storepass changeit
-noprompt
```

After fulfilling these steps you should obtain keystore and truststore, as well as files with certificates and keys.

Client configuration

Java SDK example

```
props.put("security.protocol", "SSL");
props.put("ssl.truststore.password", "changeit");
props.put("ssl.truststore.location", "/full/path/to/client.truststore.jks");
props.put("ssl.keystore.location", "/full/path/to/client.keystore.jks");
props.put("ssl.keystore.password", "changeit");
props.put("ssl.key.password", "changeit");
props.put("ssl.endpoint.identification.algorithm", "");
```

Kafka cli example

```
security.protocol=SSL
ssl.truststore.password=changeit
ssl.truststore.location=/full/path/to/client.truststore.jks
ssl.keystore.location=/full/path/to/client.keystore.jks
ssl.keystore.password=changeit
ssl.key.password=changeit
ssl.endpoint.identification.algorithm=
```

YDB configuration

It is necessary to specify the required fields in the kafka_proxy_config.

```
kafka_proxy_config:
  enable_kafka_proxy: true
  listening_port: your_port

  mtls_enable: true
  key: "server-key.pem" # укажите правильные пути до файлов
  cert: "server-cert.pem"
  ca: "ca-cert.pem"
  enable_self_signed_certs: true # разрешаете ли вы самоподписанные сертификаты
```

In the client_certificate_authorization, specify the following authentication rules:

```
client_certificate_authorization:
  client_certificate_definitions:
    - require_same_issuer: true
      subject_terms:
        - short_name: CN
          suffixes:
            - '.myhost.net' # нужно заменить на нужный суффикс
      member_groups:
        - user@cert # заменить на нужную member группу
  request_client_certificate: true
```

Additionally, for proper operation, you need to use the same certificate as in the gRPC settings, so you need to specify the path to this server certificate in the grpc configuration.

Currently, it is not possible to configure Kafka and gRPC with different server certificates or to specify a server certificate only in the kafka_proxy_config settings when using mTLS.

```
grpc_config:
  cert: "/path/to/server-cert.pem"
```

Kafka API usage examples

This example shows a code snippet for reading data from a topic via Kafka API without a consumer group (Manual Partition Assignment).
You don't need to create a consumer for this reading mode.

Before proceeding with the examples:

1. Create a topic.
2. Add a consumer.
3. If authentication is enabled, create a user.

How to try the Kafka API

In Docker

Run Docker following the quickstart guide, and the Kafka API will be available on port 9092.

Kafka API usage examples

Reading

YDB Topics Kafka API lacks support for the check.crcs option. Therefore, the following parameter must always be specified in the reader configuration: `check.crcs=false`.

Below are examples of reading using the Kafka protocol for various applications, programming languages, and frameworks without authentication.
For examples of how to set up authentication, see Authentication examples.

Built-in Kafka CLI tools

> **Note**
>
> If you get the `java.lang.UnsupportedOperationException: getSubject is supported only if a security manager is allowed` error when using Kafka CLI tools with Java 23, perform one of the following steps:
>
> - Run the command using a different version of Java (how to change the Java version on macOS).
> - Run the command with the Java flag `-Djava.security.manager=allow`. For example: `KAFKA_OPTS=-Djava.security.manager=allow kafka-topics --bootstrap-servers localhost:9092 --list`.

```
kafka-console-consumer --bootstrap-server localhost:9092 \
    --topic my-topic  \
    --group my-group \
    --from-beginning \
    --consumer-property check.crcs=false \
    --consumer-property partition.assignment.strategy=org.apache.kafka.clients.consumer.RoundRobinAssignor
```

kcat

```
kcat -C \
  -b <ydb-endpoint> \
  -X check.crcs=false \
  -X partition.assignment.strategy=org.apache.kafka.clients.consumer.RoundRobinAssignor \
  -G <consumer-name> <topic-name>
```

Java

```
String HOST = "<ydb-endpoint>";
String TOPIC = "<topic-name>";
String CONSUMER = "<consumer-name>";

Properties props = new Properties();

props.put("bootstrap.servers", HOST);

props.put("key.deserializer", StringDeserializer.class.getName());
props.put("value.deserializer", StringDeserializer.class.getName());

props.put("check.crcs", false);
props.put("partition.assignment.strategy", RoundRobinAssignor.class.getName());

props.put("group.id", CONSUMER);
Consumer<String, String> consumer = new KafkaConsumer<>(props);
consumer.subscribe(Arrays.asList(new String[] {TOPIC}));

while (true) {
  ConsumerRecords<String, String> records = consumer.poll(10000); // timeout 10 sec
  for (ConsumerRecord<String, String> record : records) {
      System.out.println(record.key() + ":" + record.value());
  }
}
```

Spark

```
public class ExampleReadApp {
  public static void main(String[] args) {
    var conf = new SparkConf().setAppName("my-app").setMaster("local");
    var context = new SparkContext(conf);

    context.setCheckpointDir("checkpoints");
    SparkSession spark = SparkSession.builder()
            .sparkContext(context)
            .config(conf)
            .appName("Simple Application")
            .getOrCreate();

    Dataset<Row> df = spark
            .read()
            .format("kafka")
            .option("kafka.bootstrap.servers", "localhost:9092")
            .option("subscribe", "flink-demo-input-topic")
            .option("kafka.group.id", "spark-example-app")
            .option("startingOffsets", "earliest")
            .option("kafka." + ConsumerConfig.CHECK_CRCS_CONFIG, "false")
            .load();

    df.foreach((ForeachFunction<Row>) row -> {
        System.out.println(row);
    });
  }
}
```

In the example above, Apache Spark 2.12:3.5.3, with a dependency on `org.apache.spark:spark-streaming-kafka-0-10_2.12:3.5.3`, was used.

Flink

```
public class YdbKafkaApiReadExample {

    public static void main(String[] args) throws Exception {
        final StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment()
                .enableCheckpointing(5000, CheckpointingMode.AT_LEAST_ONCE);

        Configuration config = new Configuration();
        config.set(CheckpointingOptions.CHECKPOINT_STORAGE, "filesystem");
        config.set(CheckpointingOptions.CHECKPOINTS_DIRECTORY, "file:///path/to/your/checkpoints");
        env.configure(config);

        KafkaSource<String> kafkaSource = KafkaSource.<String>builder()
                .setBootstrapServers("localhost:9092")
                .setProperty(ConsumerConfig.CHECK_CRCS_CONFIG, "false")
                .setGroupId("flink-demo-consumer")
                .setTopics("my-topic")
                .setStartingOffsets(OffsetsInitializer.earliest())
                .setBounded(OffsetsInitializer.latest())
                .setValueOnlyDeserializer(new SimpleStringSchema())
                        .build();

        env.fromSource(kafkaSource, WatermarkStrategy.noWatermarks(), "kafka-source").print();

        env.execute("YDB Kafka API example read app");
    }
}
```

In the example above, Apache Flink 1.20 is used with the Flink DataStream connector for Kafka.

Writing

Built-in Kafka CLI tools

> **Note**
>
> If you get the `java.lang.UnsupportedOperationException: getSubject is supported only if a security manager is allowed` error when using Kafka CLI tools with Java 23, perform one of the following steps:
>
> - Run the command using a different version of Java (how to change the Java version on macOS).
> - Run the command with the Java flag `-Djava.security.manager=allow`. For example: `KAFKA_OPTS=-Djava.security.manager=allow kafka-topics --bootstrap-servers localhost:9092 --list`.

```
kafka-console-producer --broker-list localhost:9092 --topic my-topic
```

kcat

```
echo "test message" | kcat -P \
    -b <ydb-endpoint> \
    -t <topic-name> \
    -k key
```

Java

```
String HOST = "<ydb-endpoint>";
String TOPIC = "<topic-name>";

Properties props = new Properties();
props.put("bootstrap.servers", HOST);
props.put("acks", "all");

props.put("key.serializer", StringSerializer.class.getName());
props.put("key.deserializer", StringDeserializer.class.getName());
props.put("value.serializer", StringSerializer.class.getName());
props.put("value.deserializer", StringDeserializer.class.getName());

props.put("compression.type", "none");

Producer<String, String> producer = new KafkaProducer<>(props);
producer.send(new ProducerRecord<String, String>(TOPIC, "msg-key", "msg-body"));
producer.flush();
producer.close();
```

Spark

```
public class ExampleWriteApp {
public static void main(String[] args) {
    var conf = new SparkConf().setAppName("my-app").setMaster("local");
    var context = new SparkContext(conf);
    context.setCheckpointDir("path/to/dir/with/checkpoints");
    SparkSession spark = SparkSession.builder()
        .sparkContext(context)
          .config(conf)
          .appName("Simple Application")
          .getOrCreate();

    spark
          .createDataset(List.of("spark-1", "spark-2", "spark-3", "spark-4"), Encoders.STRING())
          .write()
          .format("kafka")
          .option("kafka.bootstrap.servers", "localhost:9092")
          .option("topic", "flink-demo-output-topic")
          .option("kafka.group.id", "spark-example-app")
          .option("startingOffsets", "earliest")
          .save();
  }
}
```

In the example above, Apache Spark 2.12:3.5.3, with a dependency on `org.apache.spark:spark-streaming-kafka-0-10_2.12:3.5.3`, was used.

Flink

```
public class YdbKafkaApiProduceExample {
  private static final String TOPIC = "my-topic";

  public static void main(String[] args) throws Exception {
      final StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();

      Sink<String> kafkaSink = KafkaSink.<String>builder()
              .setBootstrapServers("localhost:9092") // assuming ydb is running locally with kafka proxy on 9
092 port
              .setRecordSerializer(KafkaRecordSerializationSchema.builder()
                      .setTopic(TOPIC)
                      .setValueSerializationSchema(new SimpleStringSchema())
                      .setKeySerializationSchema(new SimpleStringSchema())
                      .build())
              .setRecordSerializer((el, ctx, ts) -> new ProducerRecord<>(TOPIC, el.getBytes()))
              .setDeliveryGuarantee(DeliveryGuarantee.AT_LEAST_ONCE)
                      .build();

      env.setParallelism(1)
              .fromSequence(0, 10)
              .map(i -> i + "")
              .sinkTo(kafkaSink);

      // Execute program, beginning computation.
      env.execute("ydb_kafka_api_write_example");
  }
}
```

In the example above, Apache Flink 1.20 is used with the Flink DataStream connector for Kafka.

Logstash

```
output {
  kafka {
    codec => json
    topic_id => "<topic-name>"
    bootstrap_servers => "<ydb-endpoint>"
    compression_type => none
  }
}
```

Fluent Bit

```
[OUTPUT]
  name                         kafka
  match                        *
  Brokers                      <ydb-endpoint>
  Topics                       <topic-name>
  rdkafka.client.id            Fluent-bit
  rdkafka.request.required.acks 1
  rdkafka.log_level            7
  rdkafka.sasl.mechanism       PLAIN
```

Authentication examples

For more details on authentication, see the Authentication section. Below are examples of authentication in a cloud database and a local database.

> **Note**
>
> Currently, the only available authentication mechanism with Kafka API in YDB Topics is `SASL_PLAIN`.

Authentication examples in on-prem YDB

To use authentication in a multinode self-deployed database:

1. Create a user. How to do this in YQL. How to execute YQL from CLI.
2. Connect to the Kafka API as shown in the examples below. In all examples, it is assumed that:
   - YDB is running locally with the environment variable `YDB_KAFKA_PROXY_PORT=9092`, meaning that the Kafka API is available at `localhost:9092`. For example, you can run YDB in Docker as described here.
   - is the username you specified when creating the user.
   - is the user's password you specified when creating the user.

Examples are shown for reading, but the same configuration parameters work for writing to a topic as well.

Built-in Kafka CLI tools

> **Note**
>
> If you get the `java.lang.UnsupportedOperationException: getSubject is supported only if a security manager is allowed` error when using Kafka CLI tools with Java 23, perform one of the following steps:
>
> - Run the command using a different version of Java (how to change the Java version on macOS).
> - Run the command with the Java flag `-Djava.security.manager=allow`. For example: `KAFKA_OPTS=-Djava.security.manager=allow kafka-topics --bootstrap-servers localhost:9092 --list`.

```
kafka-console-consumer --bootstrap-server localhost:9092 \
--topic <topic-name>  \
--group <consumer-name> \
--from-beginning \
--consumer-property check.crcs=false \
--consumer-property partition.assignment.strategy=org.apache.kafka.clients.consumer.RoundRobinAssignor \
--consumer-property security.protocol=SASL_PLAINTEXT \
--consumer-property sasl.mechanism=PLAIN \
--consumer-property "sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule required username=\"<username>\" password=\"<password>\";"
```

kcat

```
kcat -C \
  -b localhost:9092 \
  -X security.protocol=SASL_PLAINTEXT \
  -X sasl.mechanism=PLAIN \
  -X sasl.username="<username>" \
  -X sasl.password="<password>" \
  -X check.crcs=false \
  -X partition.assignment.strategy=roundrobin \
  -G <consumer-name> <topic-name>
```

Java

```
String TOPIC = "<topic-name>";
String CONSUMER = "<consumer-name>";

Properties props = new Properties();

props.put("bootstrap.servers", "localhost:9092");

props.put("key.deserializer", StringDeserializer.class.getName());
props.put("value.deserializer", StringDeserializer.class.getName());

props.put("check.crcs", false);
props.put("partition.assignment.strategy", RoundRobinAssignor.class.getName());

props.put("security.protocol", "SASL_PLAINTEXT");
props.put("sasl.mechanism", "PLAIN");
props.put("sasl.jaas.config", "sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule requi
red username=\"<username>\" password=\"<password>\";");

props.put("group.id", CONSUMER);
Consumer<String, String> consumer = new KafkaConsumer<>(props);
consumer.subscribe(Arrays.asList(new String[] {TOPIC}));

while (true) {
  ConsumerRecords<String, String> records = consumer.poll(10000); // timeout 10 sec
  for (ConsumerRecord<String, String> record : records) {
      System.out.println(record.key() + ":" + record.value());
  }
}
```

Using Kafka Connect

This section provides configuration examples for popular Kafka Connect connectors to use with YDB.

Kafka Connect is a tool for streaming data between Apache Kafka® and other data stores. YDB supports its topics over the Kafka protocol, so you can use Kafka Connect connectors to work with YDB.

For more information about Kafka Connect and its configuration, see the Apache Kafka® documentation.

Configuring Kafka Connect. A step-by-step guide

This section provides a step-by-step guide for configuring a Kafka Connect connector to copy data from a YDB topic to a file.

The following placeholders are used in this guide:

- `<topic-name>` — the topic name. You can specify either the full name (including the database path) or just the topic name.
- `<sasl.username>` — the SASL username. For more details, see the Authentication section.
- `<sasl.password>` — the SASL password. For more details, see the Authentication section.

1. Create a consumer named `connect-<connector-name>`. The connector name is specified in the `name` field of its configuration file.
2. Download and unpack the Apache Kafka® archive:

   ```
   wget https://downloads.apache.org/kafka/3.6.1/kafka_2.13-3.6.1.tgz && tar -xvf kafka_2.13-3.6.1.tgz --st
   rip 1 --directory /opt/kafka/
   ```

   This example uses Apache Kafka® version `3.6.1`.
3. Create a directory for the worker process configuration:

   ```
   sudo mkdir --parents /etc/kafka-connect-worker
   ```

4. Create the worker process configuration file `/etc/kafka-connect-worker/worker.properties`:

   ```
   # Main properties
   bootstrap.servers=<ydb-endpoint>

   # AdminAPI properties
   sasl.mechanism=PLAIN
   security.protocol=SASL_SSL
   sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule required username="<sasl.userna
   me>" password="<sasl.password>";

   # Producer properties
   producer.sasl.mechanism=PLAIN
   producer.security.protocol=SASL_SSL
   producer.sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule required username="<sa
   sl.username>" password="<sasl.password>";

   # Consumer properties
   consumer.sasl.mechanism=PLAIN
   consumer.security.protocol=SASL_SSL
   consumer.sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule required username="<sa
   sl.username>" password="<sasl.password>";

   consumer.check.crcs=false

   # Converter properties
   key.converter=org.apache.kafka.connect.storage.StringConverter
   value.converter=org.apache.kafka.connect.storage.StringConverter
   key.converter.schemas.enable=false
   value.converter.schemas.enable=false

   # Worker properties
   plugin.path=/etc/kafka-connect-worker/plugins
   ```

5. Create the configuration file `/etc/kafka-connect-worker/file-sink.properties` for the FileSink connector to copy data from a YDB topic to a file:

   ```
   name=local-file-sink
   connector.class=FileStreamSink
   tasks.max=1
   file=/etc/kafka-connect-worker/file_to_write.json
   topics=<topic-name>
   ```

   Where:

   - `file` - the name of the file where the connector will write data.
   - `topics` - the name of the topic from which the connector will read data.
6. Run Kafka Connect in standalone mode:

   ```
   cd ~/opt/kafka/bin/ && \
   sudo ./connect-standalone.sh \
           /etc/kafka-connect-worker/worker.properties \
           /etc/kafka-connect-worker/file-sink.properties
   ```

Connector configuration examples

This section provides sample Kafka Connect connector configuration files for working with YDB over the Kafka protocol.

From a file to a YDB topic

Example configuration file `/etc/kafka-connect-worker/file-sink.properties` for the FileSource connector to stream data from a file to a topic:

```
name=local-file-source
connector.class=FileStreamSource
tasks.max=1
file=/etc/kafka-connect-worker/file_to_read.json
topic=<topic-name>
```

From YDB to PostgreSQL

Example configuration file, `/etc/kafka-connect-worker/jdbc-sink.properties`, for the JDBC Sink connector to stream data from a topic to a PostgreSQL table. This example uses the Kafka Connect JDBC Connector.

```
name=postgresql-sink
connector.class=io.confluent.connect.jdbc.JdbcSinkConnector

connection.url=jdbc:postgresql://<postgresql-host>:<postgresql-port>/<db>
connection.user=<pg-user>
connection.password=<pg-user-pass>

topics=<topic-name>
batch.size=2000
auto.commit.interval.ms=1000

transforms=wrap
transforms.wrap.type=org.apache.kafka.connect.transforms.HoistField$Value
transforms.wrap.field=data

auto.create=true
insert.mode=insert
pk.mode=none
auto.evolve=true
```

From PostgreSQL to YDB

Example configuration file `/etc/kafka-connect-worker/jdbc-source.properties` for the JDBC Source connector to stream data from a PostgreSQL table to a topic. This example uses the Kafka Connect JDBC Connector.

```
name=postgresql-source
connector.class=io.confluent.connect.jdbc.JdbcSourceConnector

connection.url=jdbc:postgresql://<postgresql-host>:<postgresql-port>/<db>
connection.user=<pg-user>
connection.password=<pg-user-pass>

mode=bulk
query=SELECT * FROM "<topic-name>";
topic.prefix=<topic-name>
poll.interval.ms=1000
validate.non.null=false
```

From YDB to S3

Example configuration file `/etc/kafka-connect-worker/s3-sink.properties` for the S3 Sink connector to stream data from a topic to S3. This example uses Aiven's S3 Sink Connector for Apache Kafka.

```
name=s3-sink
connector.class=io.aiven.kafka.connect.s3.AivenKafkaConnectS3SinkConnector
topics=<topic-name>
aws.access.key.id=<s3-access-key>
aws.secret.access.key=<s3-secret>
aws.s3.bucket.name=<bucket-name>
aws.s3.endpoint=<s3-endpoint>
format.output.type=json
file.compression.type=none
```

Kafka API constraints

YDB supports Apache Kafka protocol version 3.4.0 with the following constraints:

1. Message compression is not supported.
2. The topic deletion operation is not supported. To delete a topic, use YQL or YDB CLI.
3. CRC checks are not supported.
4. Support for ACL is not provided. Use YQL to manage access to topics.
5. If auto-partitioning is enabled on a topic, you cannot write to or read from such a topic using the Kafka API.

Amazon SQS API

YDB supports working with topics via the Amazon SQS protocol.

> **Note**
>
> Working with topics via the Amazon SQS protocol is supported only for Amazon JSON protocol.

Work with a single topic can be done simultaneously using multiple protocols. For example, writing can be done using the Topic API, and reading using the Amazon SQS API, and vice versa.

When creating a topic using the `CreateQueue` Amazon SQS API command, the topic is created with auto-partitioning enabled: with one partition and the automatic ability to increase up to 10 active partitions. Auto-partitioning parameters can be changed via YQL or YDB CLI.

Reading via Amazon SQS API

For reading via Amazon SQS API, a shared (common) reader is used, which must be created on the topic before reading via the Amazon SQS protocol. If the topic is created using the `CreateQueue` Amazon SQS API command, a shared (common) reader named `ydb-sqs-consumer` is automatically created.

Messages written via the Topic API may be compressed using gzip, lzop, or zstd algorithms. When reading via the Amazon SQS protocol, the server does not decompress them but transmits them as base64: the reader must perform base64 decoding and then decompression.

Messages written via the Topic API without compression may contain binary data. When reading via the Amazon SQS protocol, the server also encodes them in base64 — the reader must perform base64 decoding.

To allow the reader to determine the compression algorithm, an attribute `BodyEncoding` is provided with each message. If the `BodyEncoding` attribute is missing, decompressing the message is not required. Possible attribute values: `gzip`, `lzop`, `zstd`, or `base64`.

Example of a message whose content is compressed:

```
{
    "Messages": [
        {
            "MessageId": "D523647F-5E89-560B-B1D0-152201831603",
            "ReceiptHandle": "CAAQAA==",
            "MD5OfBody": "d620a162c499920254054f78eac4feed",
            "Body": "KLUv/QBYaQAAeWRiIHdyaXRlZCAyCg==",
            "Attributes": {
                "SentTimestamp": "1780660726888",
                "BodyEncoding": "zstd"
            }
        }
    ]
}
```

Writing via Amazon SQS API

When writing to a topic via the Amazon SQS protocol, messages are evenly distributed across partitions. This guarantees that all messages with the same `MessageGroupId` end up in the same partition.

For writing via the Amazon SQS protocol, message deduplication is supported by `DeduplicationMessageId`, and if `DeduplicationMessageId` is not provided, by message content. Deduplication by content can be enabled using the `CreateQueue` and `SetQueueAttributes` commands by specifying the `ContentBasedDeduplication` parameter.

Deduplication by content is implemented with a 5-minute window: a message with a duplicate `DeduplicationMessageId` can be written again after 5 minutes or more.

There is a limit on the number of messages that can be written to a topic partition with deduplication by content enabled: 500 messages per second. If you need to write more messages to the topic, you should increase the number of partitions. The limit for a topic is calculated as 500 messages/sec/partition × number of partitions. For example, to write 10,000 messages per second, create a topic with 20 partitions.

Amazon SQS API

YDB supports working with topics via the Amazon SQS protocol.

> **Note**
>
> Working with topics via the Amazon SQS protocol is supported only for Amazon JSON protocol.

Work with a single topic can be done simultaneously using multiple protocols. For example, writing can be done using the Topic API, and reading using the Amazon SQS API, and vice versa.

When creating a topic using the `CreateQueue` Amazon SQS API command, the topic is created with auto-partitioning enabled: with one partition and the automatic ability to increase up to 10 active partitions. Auto-partitioning parameters can be changed via YQL or YDB CLI.

Reading via Amazon SQS API

For reading via Amazon SQS API, a shared (common) reader is used, which must be created on the topic before reading via the Amazon SQS protocol. If the topic is created using the `CreateQueue` Amazon SQS API command, a shared (common) reader named `ydb-sqs-consumer` is automatically created.

Messages written via the Topic API may be compressed using gzip, lzop, or zstd algorithms. When reading via the Amazon SQS protocol, the server does not decompress them but transmits them as base64: the reader must perform base64 decoding and then decompression.

Messages written via the Topic API without compression may contain binary data. When reading via the Amazon SQS protocol, the server also encodes them in base64 — the reader must perform base64 decoding.

To allow the reader to determine the compression algorithm, an attribute `BodyEncoding` is provided with each message. If the `BodyEncoding` attribute is missing, decompressing the message is not required. Possible attribute values: `gzip`, `lzop`, `zstd`, or `base64`.

Example of a message whose content is compressed:

```
{
    "Messages": [
        {
            "MessageId": "D523647F-5E89-560B-B1D0-152201831603",
            "ReceiptHandle": "CAAQAA==",
            "MD5OfBody": "d620a162c499920254054f78eac4feed",
            "Body": "KLUv/QBYaQAAeWRiIHdyaXRlZCAyCg==",
            "Attributes": {
                "SentTimestamp": "1780660726888",
                "BodyEncoding": "zstd"
            }
        }
    ]
}
```

Writing via Amazon SQS API

When writing to a topic via the Amazon SQS protocol, messages are evenly distributed across partitions. This guarantees that all messages with the same `MessageGroupId` end up in the same partition.

For writing via the Amazon SQS protocol, message deduplication is supported by `DeduplicationMessageId`, and if `DeduplicationMessageId` is not provided, by message content. Deduplication by content can be enabled using the `CreateQueue` and `SetQueueAttributes` commands by specifying the `ContentBasedDeduplication` parameter.

Deduplication by content is implemented with a 5-minute window: a message with a duplicate `DeduplicationMessageId` can be written again after 5 minutes or more.

There is a limit on the number of messages that can be written to a topic partition with deduplication by content enabled: 500 messages per second. If you need to write more messages to the topic, you should increase the number of partitions. The limit for a topic is calculated as 500 messages/sec/partition × number of partitions. For example, to write 10,000 messages per second, create a topic with 20 partitions.

- Creating a queue using YQL
- Shared topic consumer: architecture and limitations

Authentication

In the Open Source version of YDB, working with topics via the Amazon SQS protocol is supported only without authentication.

Cluster setup

To disable authentication, in the `security_config` section of the cluster configuration file, set the `enforce_user_token_requirement` parameter to `false`:

```
security_config:
  enforce_user_token_requirement: false
```

Examples of working with topics via Amazon SQS API

This article provides examples of working with topics using the Amazon SQS API via AWS CLI.

> **Note**
>
> Working with topics via the Amazon SQS protocol is supported only for Amazon JSON protocol.

Before running the examples, configure access to the Amazon SQS API (in the Open Source version, disable the authentication requirement — see the section on authentication).

If you use AWS CLI, make sure it does not require configured AWS credentials: either add `--no-sign-request` to the commands, or set any values for `AWS_ACCESS_KEY_ID` / `AWS_SECRET_ACCESS_KEY`.

Forming the endpoint for connection

The endpoint for accessing the Amazon SQS API is formed as follows:

```
https://{db-balancer}:{port}/{database}
```

Where:

- `db-balancer` — DNS name of the HTTPS balancer whose backend includes the database compute nodes (or the address of the node/service where the HTTP Proxy is running).
- `port` — port on which the HTTP Proxy is available.
- `database` — full path of the database where the topics are located.

This endpoint is specified in AWS CLI via the `--endpoint` parameter.

> **Note**
>
> The examples use the endpoint `https://my_db.balancer.example.com:8443/Root/my_db`. It includes:
>
> - `my_db.balancer.example.com` — DNS name of the balancer through which the Amazon SQS protocol is available.
> - `8443` — network port.
> - `/Root/my_db` — database name.

Creating a topic

To create a topic, run the command:

```
ENDPOINT="https://my_db.balancer.example.com:8443/Root/my_db"

aws --endpoint "$ENDPOINT" \
  sqs create-queue --queue-name "my_topic"
```

After executing the command, a topic with the specified name and a shared (common) reader named `ydb-sqs-consumer` will be created. You can verify the topic's existence using the scheme describe command of the YDB CLI:

```
ydb -e grpcs://my_db.balancer.example.com:2135 -d /Root/my_db scheme describe my_topic
```

To create a FIFO queue, use the `FifoQueue=true` attribute. For FIFO queues, it is recommended to end the name with `.fifo` to comply with the Amazon SQS naming convention:

```
ENDPOINT="https://my_db.balancer.example.com:8443/Root/my_db"

aws --endpoint "$ENDPOINT" \
  sqs create-queue \
  --queue-name "my_topic.fifo" \
  --attributes FifoQueue=true
```

After executing the command, a topic named `my_topic.fifo` and a shared (common) reader named `ydb-sqs-consumer` will be created, with message ordering preservation enabled.

Getting a list of topics

To get a list of topics that can be worked with via the Amazon SQS protocol, run the command:

```
ENDPOINT="https://my_db.balancer.example.com:8443/Root/my_db"

aws --endpoint "$ENDPOINT" sqs list-queues
```

Getting the QueueUrl of a topic

To get the `QueueUrl` of a topic, run the command:

```
ENDPOINT="https://my_db.balancer.example.com:8443/Root/my_db"

aws --endpoint "$ENDPOINT" sqs get-queue-url \
  --queue-name "my_topic@my_consumer"
```

Where:

- `{queue_name}` — value of the `--queue-name` parameter, the Amazon SQS queue name in the format `{topic_name}@{consumer_name}`. If the shared (common) reader has the name `ydb-sqs-consumer`, it is sufficient to specify only `{topic_name}`.
- `{topic_name}` — topic name with the path from the root of the database where it was created, for example `production/order` (topic `order` in directory `production`).
- `{consumer_name}` — name of the shared (common) reader on the topic, for example `ydb-sqs-consumer`.

In the example above, `my_topic` is `{topic_name}`, and `my_consumer` is `{consumer_name}`.

Writing to a topic and reading from a topic

For read and write operations, AWS CLI uses the `--queue-url` parameter. It can be obtained via `get-queue-url`.

Below is an example:

- getting `QueueUrl`.
- writing a message.
- reading a message.

```
ENDPOINT="https://my_db.balancer.example.com:8443/Root/my_db"

# get QueueUrl
QUEUE_URL="$(aws --endpoint "$ENDPOINT" sqs get-queue-url --queue-name "my_topic" --query 'QueueUrl' --output
text)"

# write a message to a topic
aws --endpoint "$ENDPOINT" sqs send-message \
  --queue-url "$QUEUE_URL" \
  --message-body "hello from aws cli"

# read a message (long polling)
aws --endpoint "$ENDPOINT" sqs receive-message \
  --queue-url "$QUEUE_URL" \
  --wait-time-seconds 20 \
  --max-number-of-messages 1
```

YDB Cluster Configuration

The cluster configuration is specified in the YAML file passed in the `--yaml-config` parameter when the cluster nodes are run. This article provides an overview of the main configuration sections and links to detailed documentation for each section.

Each configuration section serves a specific purpose in defining how the YDB cluster operates, from hardware resource allocation to security settings and feature flags. The configuration is organized into logical groups that correspond to different aspects of cluster management and operation.

Configuration Sections

The following top-level configuration sections are available, listed in alphabetical order:

Section	Required	Description
actor_system_config	Yes	CPU resource allocation across actor system pools
auth_config	No	Authentication and authorization settings
aws_client_config	No	AWS client default settings
blob_storage_config	No	Static cluster group configuration for system tablets
bridge_config	No	Cluster piles for bridge mode
client_certificate_authorization	No	Client certificate authentication
cms_config	No	Cluster Management System configuration
domains_config	No	Cluster domain configuration including Blob Storage and State Storage
feature_flags	No	Feature flags to enable or disable specific YDB features
healthcheck_config	No	Health check service thresholds and timeout settings
hive_config	No	Hive component configuration for tablet management
host_configs	No	Typical host configurations for cluster nodes
hosts	Yes	Static cluster nodes configuration
immediate_controls_config	No	Configuration of dynamic cluster settings
kafka_proxy_config	No	Kafka Proxy configuration
log_config	No	Logging configuration and parameters
memory_controller_config	No	Memory allocation and limits for database components
node_broker_config	No	Stable node names configuration
query_service_config	No	Federated query connector configuration
resource_broker_config	No	Resource broker for controlling CPU and memory consumption
security_config	No	Security configuration settings
table_service_config	No	Query processing configuration
tli_config	No	Transaction lock invalidation (TLI) diagnostics parameters
tls	No	TLS configuration for secure connections

Practical Guidelines

While this documentation section focuses on complete reference documentation for available settings, practical recommendations on what to tune and when can be found in the following places:

- As part of the initial YDB cluster deployment:
  - Ansible
  - Kubernetes
  - Manual
- As part of troubleshooting
- As part of security hardening

Sample Cluster Configurations

You can find model cluster configurations for deployment in the repository. Check them out before deploying a cluster.

actor_system_config

The CPU resources are mainly used by the actor system. Depending on the type, all actors run in one of the pools (the `name` parameter). Configuration involves allocating a node's CPU cores across the actor system pools. When allocating them, please keep in mind that PDisks and the gRPC API run outside the actor system and require separate resources.

You can set up your actor system either automatically or manually. In the `actor_system_config` section, specify:

- Node type and the number of CPU cores allocated to the ydbd process by automatic configuration.
- Number of CPU cores for each YDB cluster subsystem in the case of manual configuration.

Automatic configuration adapts to the current system workload. It is recommended in most cases.

You might opt for manual configuration when a certain pool in your actor system is overwhelmed and undermines the overall database performance. You can track the workload on your pools on the YDB UI monitoring page.

Automatic Configuring

Regardless of the `node_type` parameter value, if one or more pools are starving (experiencing a shortage of compute resources), core redistribution follows the priority order below (highest to lowest):

- `IC`
- `System`
- `User`
- `Batch`

For example, if `IC` and `User` are starving while `System` has idle cores, `IC` receives them.

Example of the `actor_system_config` section for automatic configuration of the actor system:

```
actor_system_config:
  use_auto_config: true
  node_type: STORAGE
  cpu_count: 10
```

Parameter	Description
`use_auto_config`	Enabling automatic configuration of the actor system.
`node_type`	Node type. Determines the expected workload and vCPU ratio between the pools. Possible values: • `STORAGE`: The node interacts with network block store volumes and is responsible for managing the Distributed Storage. • `COMPUTE`: The node processes the workload generated by users. • `HYBRID`: The node is used for hybrid load or the usage of `System`, `User`, and `IC` for the node under load is about the same.
`cpu_count`	Number of vCPUs allocated to the node.

Manual Configuring

Example of the `actor_system_config` section for manual configuration of the actor system:

```
actor_system_config:
  executor:
  - name: System
    spin_threshold: 0
    threads: 2
    type: BASIC
  - name: User
    spin_threshold: 0
    threads: 3
    type: BASIC
  - name: Batch
    spin_threshold: 0
    threads: 2
    type: BASIC
  - name: IO
    threads: 1
    time_per_mailbox_micro_secs: 100
    type: IO
  - name: IC
    spin_threshold: 10
    threads: 1
    time_per_mailbox_micro_secs: 100
    type: BASIC
  scheduler:
    progress_threshold: 10000
    resolution: 256
    spin_threshold: 0
```

Parameter	Description
`executor`	Pool configuration. You should only change the number of CPU cores (the `threads` parameter) in the pool configs.

`name`	Pool name that indicates its purpose. Possible values: • `System` : A pool that is designed for running quick internal operations in YDB (it serves system tablets, state storage, distributed storage I/O, and erasure coding). • `User` : A pool that serves the user load (user tablets, queries run in the Query Processor). • `Batch` : A pool that serves tasks with no strict limit on the execution time, background operations like garbage collection and heavy queries run in the Query Processor. • `IO` : A pool responsible for performing any tasks with blocking operations (such as authentication or writing logs to a file). • `IC` : Interconnect, it serves the load related to internode communication (system calls to wait for sending and send data across the network, data serialization, as well as message splits and merges).
`spin_threshold`	The number of CPU cycles before going to sleep if there are no messages. In sleep mode, there is less power consumption, but it may increase request latency under low loads.
`threads`	The number of CPU cores allocated per pool. Make sure the total number of cores assigned to the System, User, Batch, and IC pools does not exceed the number of available system cores.
`max_threads`	Maximum vCPU that can be allocated to the pool from idle cores of other pools. When you set this parameter, the system enables the mechanism of expanding the pool at full utilization, provided that idle vCPUs are available. The system checks the current utilization and reallocates vCPUs once per second.
`max_avg_ping_deviation`	Additional condition to expand the pool's vCPU. When more than 90% of vCPUs allocated to the pool are utilized, you need to worsen SelfPing by more than `max_avg_ping_deviation` microseconds from 10 milliseconds expected.
`time_per_mailbox_micro_secs`	The number of messages per actor to be handled before switching to a different actor.
`type`	Pool type. Possible values: • `IO` should be set for IO pools. • `BASIC` should be set for any other pool.
`scheduler`	Scheduler configuration. The actor system scheduler is responsible for the delivery of deferred messages exchanged by actors. We do not recommend changing the default scheduler parameters.
`progress_threshold`	The actor system supports requesting message sending scheduled for a later point in time. The system might fail to send all scheduled messages at some point. In this case, it starts sending them in "virtual time" by handling message sending in each loop over a period that doesn't exceed the `progress_threshold` value in microseconds and shifting the virtual time by the `progress_threshold` value until it reaches real time.
`resolution`	When making a schedule for sending messages, discrete time slots are used. The slot duration is set by the `resolution` parameter in microseconds.

auth_config

Configuration

YDB supports various user authentication methods. The configuration for authentication providers is specified in the `auth_config` section.

Configuring Local YDB User Authentication

For more information about the authentication of local YDB users, see Authenticating by username and password. To configure authentication by username and password, define the following parameters in the `auth_config` section:

Parameter	Description
use_login_provider	Indicates whether to allow the authentication of local users with an authentication token that is obtained after entering a username and password. Default value: `true`
enable_login_authentication	Indicates whether to allow adding local users to YDB databases and generating authentication tokens after a local user enters a username and password. Default value: `true`
domain_login_only	Determines the scope of local user access rights in a YDB cluster. Valid values: • `true` — local users exist in a YDB cluster and can be granted rights to access multiple databases. • `false` — local users can exist either at the cluster or database level. The scope of access rights for local users created at the database level is limited to the database, in which they are created. Default value: `true`
login_token_expire_time	Specifies the expiration time of the authentication token created when a local user logs in to YDB. Default value: `12h`

Configuring User Lockout

You can configure YDB to lock a user account out after a specified number of failed attempts to enter the correct password. To configure user lockout, define the `account_lockout` subsection inside the `auth_config` section.

Example of the `account_lockout` section:

```
auth_config:
  #...
  account_lockout:
    attempt_threshold: 4
    attempt_reset_duration: "1h"
  #...
```

Parameter	Description
attempt_threshold	Specifies the number of failed attempts to enter the correct password for a user account, after which the account is blocked for a period specified by the `attempt_reset_duration` parameter. If `attempt_threshold = 0`, the number of attempts to enter the correct password is unlimited. After successful authentication (correct username and password), the counter for failed attempts is reset to 0. Default value: `4`
attempt_reset_duration	Specifies the period that a locked-out account remains locked before automatically becoming unlocked. This period starts after the last failed attempt. During this period, the user will not be able to authenticate in the system even if the correct username and password are entered. If this parameter is set to zero ("0s" - a notation equivalent of 0 seconds), user accounts will be locked indefinitely. In this case you can unlock the account using the ALTER USER ... LOGIN command. The minimum lockout duration is 1 second. Supported time units: • Seconds: `30s` • Minutes: `20m` • Hours: `5h` • Days: `3d` It is not allowed to combine time units in one entry. For example, the entry `1d12h` is incorrect. It should be replaced with an equivalent, such as `36h`. Default value: `1h`

Configuring Password Complexity Requirements

YDB allows local users to authenticate using a login and password. For more information, see authentication by login and password. To enhance security in YDB, configure complexity requirements for the passwords of local users in the `password_complexity` subsection inside the `auth_config` section.

Example of the `password_complexity` section:

```
auth_config:
  #...
  password_complexity:
    min_length: 8
    min_lower_case_count: 1
    min_upper_case_count: 1
    min_numbers_count: 1
    min_special_chars_count: 1
    special_chars: "!@#$%^&*()_+{}|<>?="
    can_contain_username: false
  #...
```

Parameter	Description
min_length	Specifies the minimum password length. Default value: `0` (no requirements)
min_lower_case_count	Specifies the minimum number of lowercase letters that a password must contain. Default value: `0` (no requirements)
min_upper_case_count	Specifies the minimum number of uppercase letters that a password must contain. Default value: `0` (no requirements)
min_numbers_count	Specifies the minimum number of digits that a password must contain. Default value: `0` (no requirements)
min_special_chars_count	Specifies the minimum number of special characters from the `special_chars` list that a password must contain. Default value: `0` (no requirements)
special_chars	Specifies a list of special characters that are allowed in a password. Valid values: `!@#$%^&*()_+{}\|<>?=` Default value: empty (any of the `!@#$%^&*()_+{}|<>?=` characters are allowed)
can_contain_username	Indicates whether passwords can include a username. Default value: `false`

Note

Any changes to the password policy do not affect existing user passwords, so it is not necessary to change current passwords; they will be accepted as they are.

Configuring LDAP Authentication

One of the user authentication methods in YDB is using an LDAP directory. For more details, see Interacting with the LDAP directory. To configure LDAP authentication, define the `ldap_authentication` section inside the `auth_config` section.

Example of the `ldap_authentication` section:

```
auth_config:
  #...
  ldap_authentication:
    hosts:
      - "ldap-hostname-01.example.net"
      - "ldap-hostname-02.example.net"
      - "ldap-hostname-03.example.net"
    port: 389
    base_dn: "dc=mycompany,dc=net"
    bind_dn: "cn=serviceAccaunt,dc=mycompany,dc=net"
    bind_password: "serviceAccauntPassword"
    search_filter: "uid=$username"
    scheme: "ldap"
    requested_group_attribute: "memberOf"
    extended_settings:
      enable_nested_groups_search: true
    use_tls:
      enable: true
      ca_cert_file: "/path/to/ca.pem"
      cert_require: DEMAND
  ldap_authentication_domain: "ldap"
  refresh_time: "1h"
  #...
```

Parameter	Description
`hosts`	Specifies a list of hostnames where the LDAP server is running.
`port`	Specifies the port used to connect to the LDAP server.

`base_dn`	Specifies the root of the subtree in the LDAP directory from which the user entry search begins.
`bind_dn`	Specifies the Distinguished Name (DN) of the service account used to search for the user entry.
`bind_password`	Specifies the password for the service account used to search for the user entry.
`search_filter`	Specifies a filter for searching the user entry in the LDAP directory. The filter string can include the sequence *$username*, which is replaced with the username requested for authentication in the database.
`use_tls`	Configuration settings for the TLS connection between YDB and the LDAP server.
`enable`	Indicates whether a TLS connection using the `StartTls` request will be attempted. When set to `true`, the `ldaps` connection scheme should be disabled by setting `ldap_authentication.scheme` to `ldap`.
`ca_cert_file`	Specifies the path to the certification authority's certificate file.
`cert_require`	Specifies the certificate requirement level for the LDAP server. Possible values: • `NEVER` - YDB does not request a certificate or accepts any presented certificate. • `ALLOW` - YDB requests a certificate from the LDAP server but will establish the TLS session even if the certificate is not trusted. • `TRY` - YDB requires a certificate from the LDAP server and terminates the connection if it is not trusted. • `DEMAND` / `HARD` - These are equivalent to `TRY` and are the default setting, with the value set to `DEMAND`.
`ldap_authentication_domain`	Specifies an identifier appended to the username to distinguish LDAP directory users from those authenticated using other providers. Default value: `ldap`
`scheme`	Specifies the connection scheme to the LDAP server. Possible values: • `ldap` - Connects without encryption, sending passwords in plain text. • `ldaps` - Connects using TLS encryption from the first request. To use `ldaps`, disable the `StartTls` request by setting `ldap_authentication.use_tls.enable` to `false`, and provide certificate details in `ldap_authentication.use_tls.ca_cert_file` and set the certificate requirement level in `ldap_authentication.use_tls.cert_require`. • Any other value defaults to `ldap`. Default value: `ldap`
`requested_group_attribute`	Specifies the attribute used for reverse group membership. The default is `memberOf`.
`extended_settings.enable_nested_groups_search`	Indicates whether to perform a request to retrieve the full hierarchy of groups to which the user's direct groups belong. Possible values: • `true` — YDB requests information about all groups to which the user's direct groups belong. It might take a long time to traverse the entire hierarchy of nested parent groups. • `false` — YDB requests a flat list of groups, to which the user belongs. This request does not traverse possible nested parent groups. Default value: `false`
`host`	Specifies the hostname of the LDAP server. This parameter is deprecated and should be replaced with the `hosts` parameter.

Configuring Third-Party IAM Authentication

YDB supports Yandex Identity and Access Management (IAM) used in Yandex Cloud for user authentication. To configure IAM authentication, define the following parameters:

Parameter	Description
use_access_service	Indicates whether to allow authentication in Yandex Cloud using IAM AccessService. Default value: `false`
access_service_endpoint	Specifies an IAM AccessService address, to which YDB sends requests. Default value: `as.private-api.cloud.yandex.net:4286`
use_access_service_tls	Indicates whether to use TLS connections between YDB and AccessService. Default value: `true`

access_service_domain	Specifies an identifier appended to the username in SID to distinguish Yandex Cloud IAM users from those authenticated using other providers. Default value: `as` ("access service")
path_to_root_ca	Specifies the path to the certification authority's certificate file that is used to interact with AccessService. Default value: `/etc/ssl/certs/YandexInternalRootCA.pem`
access_service_grpc_keep_alive_time_ms	Specifies the period of time, in milliseconds, after which a keepalive ping is sent on the transport to IAM AccessService. Default value: `10000`
access_service_grpc_keep_alive_timeout_ms	Specifies the amount of time, in milliseconds, that YDB waits for the acknowledgement of the keepalive ping from IAM AccessService. If YDB does not receive an acknowledgment within this time, it will close the connection. Default value: `1000`
use_access_service_api_key	Indicates whether to use IAM API keys. The API key is a secret key created in Yandex Cloud IAM for simplified authorization of service accounts with the Yandex Cloud API. Use API keys if requesting an IAM token automatically is not an option. Default value: `false`

Configuring Caching for Authentication Results

During the authentication process, a user session receives an authentication token, which is transmitted along with each request to the cluster YDB. Since YDB is a distributed system, user requests will eventually be processed on one or more YDB nodes. After receiving a request from the user, a YDB node verifies the authentication token. If successful, the node generates a **user token**, which is valid only inside the current node and is used to authorize the actions requested by the user. Subsequent requests with the same authentication token to the same node do not require verification of the authentication token.

To configure the life cycle and other important aspects of managing user tokens, define the following parameters:

refresh_period	Specifies how often a YDB node scans cached user tokens to find the ones that need to be refreshed because the `refresh_time`, `life_time` or `expire_time` interval elapses. The lower this parameter value, the higher the CPU load. Default value: `1s`
refresh_time	Specifies the time interval since the last user token update after which a YDB node updates the user token again. The actual update will occur within the range from `refresh_time/2` to `refresh_time`. Default value: `1h`
life_time	Specifies the time interval for keeping a user token in YDB node cache since its last use. If a YDB node does not receive queries from a user within the specified time interval, the node deletes the user token from its cache. Default value: `1h`
expire_time	Specifies the time period, after which a user token is deleted from YDB node cache. Deletion occurs regardless of the `life_time` interval. **Warning** If a third-party system has successfully authenticated in the YDB node and regularly (more often than the `life_time` interval) sends requests to the same node, YDB will detect the possible deletion or change in the user account privileges only after the `expire_time` interval elapses. The shorter this time period, the more often YDB nodes re-authenticate users and refresh their privileges. However, excessive user re-authentication slows down YDB, especially so for external users. Setting this parameter to seconds negates the effect of caching user tokens. Default value: `24h`
min_error_refresh_time	Specifies minimum period of time that must elapse since a failed attempt (temporary failure) to refresh a user token before retrying the attempt. Together with the `max_error_refresh_time`, determines the possible interval for a delay before retrying a failed attempt to refresh a user token. Each subsequent delay is increased till it reaches the `max_error_refresh_time` value. Retries continue until a user token is refreshed or the `expire_time` period elapses. **Warning** Setting this parameter to `0` is not recommended, because instant retries results in excessive load. Default value: `1s`
max_error_refresh_time	Specifies the maximum time interval that can elapse since a failed attempt (temporary failure) to refresh a user token before retrying the attempt. Together with the `min_error_refresh_time`, determines the possible interval for a delay before retrying a failed attempt to refresh a user token. Each subsequent delay is increased till it reaches the `max_error_refresh_time` value. Retries continue until a user token is refreshed or the `expire_time` period elapses. Default value: `1m`

Node registration token configuration

YDB allows you to configure the authentication method for database nodes when they register with a cluster. This is done via the `node_registration_token` parameter in the `auth_config` section.

Parameter	Description
node_registration_token	Specifies the authentication method for database nodes registering with a cluster. Possible values: • Empty string (`""`) — nodes authenticate using TLS certificates when registering with the cluster. In this mode, nodes must use certificates for authentication during the registration process. For details on configuring node authentication with certificates, see Database node authentication and authorization. • `"root@builtin"` — nodes authenticate using a special debug token when registering with the cluster. This authentication method is deprecated and will be removed in future releases. To ensure cluster security, always prefer TLS certificate-based authentication by setting this parameter to an empty string.

Example of an `auth_config` section with TLS certificate authentication enabled:

```
auth_config:
  ...
  node_registration_token: ""
  ...
```

aws_client_config

The `aws_client_config` section defines defaults for the AWS SDK client that YDB uses when accessing S3 and other object storage systems with a compatible API. It configures timeouts, TLS settings, and logging for all such outbound connections made by the cluster node process; a specific storage configuration can override these values when needed.

Syntax

```
aws_client_config:
  log_config:
    log_level: 0
    filename_prefix: ""
  verify_ssl: true
  request_timeout_ms: 0
  http_request_timeout_ms: 0
  connection_timeout_ms: 10000
  enable_tcp_keep_alive: true
  tcp_keep_alive_interval_ms: 30000
  max_connections_count: 32
  executor_threads_count: 32
  ca_path: "/etc/ssl/certs"
```

Parameters

Parameter	Default	Description
`log_config.log_level`	`0` (Off)	Numeric AWS SDK log verbosity level. See Log levels for level names and numeric values.
`log_config.filename_prefix`	—	Prefix for AWS SDK log files. When set, files are created as `<prefix>YYYY-MM-DD-HH.log`; otherwise logs go to stdout.
`verify_ssl`	`true`	Whether to validate TLS certificates when connecting to AWS endpoints and compatible APIs. Set to `false` only in test environments.
`request_timeout_ms`	`0` (disabled)	Request timeout at the AWS SDK level for the entire request, including DNS lookup, connection setup, TLS handshake, and data transfer. The value is specified in milliseconds. `0` means no SDK-side timeout limit.
`http_request_timeout_ms`	`0` (disabled)	HTTP-layer timeout in milliseconds applied by the HTTP client (Curl). `0` means no timeout.
`connection_timeout_ms`	`10000`	TCP connect timeout in milliseconds.
`enable_tcp_keep_alive`	`true`	Enables TCP keep-alive on client sockets.
`tcp_keep_alive_interval_ms`	`30000` (AWS SDK default)	Interval between TCP keep-alive probes in milliseconds. When not set in the YDB config, the AWS SDK default of 30000 ms is used. In Curl this value is rounded to whole seconds and must be at least 15000.
`max_connections_count`	`32`	Maximum number of concurrent TCP connections that the HTTP client inside AWS SDK may open.
`executor_threads_count`	`32`	Size of the thread pool allocated per unique S3 endpoint. Controls parallelism for asynchronous requests to that endpoint.
`ca_path`	`"/etc/ssl/certs"`	Path to a directory with CA certificates used to verify TLS for outbound connections.
`ca_file`	—	Path to a single CA certificate bundle file. Used when the trust store is not in the default location.

Log levels

Level	Value	Description
`Off`	`0`	Disable AWS SDK logging.
`Fatal`	`1`	Fatal errors only.
`Error`	`2`	Non-fatal errors.
`Warn`	`3`	Warnings that may need attention.
`Info`	`4`	High-level informational messages.
`Debug`	`5`	Debug information.
`Trace`	`6`	Most verbose diagnostic output.

See also

- log_config for logging of the YDB server process. The `log_config` block nested under `aws_client_config` applies only to AWS SDK and is unrelated to the server logging configuration.
- Data export and import for S3 import and export from the CLI. Storage access is configured there, not in `aws_client_config`.

Related scenarios ("S3 in YDB")

Other object storage tasks. Settings from these materials may override the values configured in the `aws_client_config` section.

- CREATE EXTERNAL DATA SOURCE for an external data source with the S3 protocol in YQL.
- Deploying YDB with Federated Query functionality for federated queries and external data sources.
- Import and export data using federated queries for import and export via federated queries to object storage.

blob_storage_config

Configuration

The `blob_storage_config` section specifies a static cluster group's configuration. A static group is necessary for the operation of the basic cluster tablets, including `Hive`, `SchemeShard`, and `BlobstorageController`. As a rule, these tablets do not store a lot of data, so we don't recommend creating more than one static group.

For a static group, specify the disks and nodes that the static group will be placed on. For example, a configuration for the `erasure: none` model can be as follows:

```
blob_storage_config:
  service_set:
    groups:
    - erasure_species: none
      rings:
      - fail_domains:
        - vdisk_locations:
          - node_id: 1
            path: /dev/disk/by-partlabel/ydb_disk_ssd_02
            pdisk_category: SSD
....
```

For a configuration located in 3 availability zones, specify 3 rings. For a configuration within a single availability zone, specify exactly one ring.

bridge_config

This section describes cluster piles for bridge mode. List the pile names used to bind hosts and other entities. In bridge mode, each host must also specify the corresponding pile name in the `hosts` section (`bridge_pile_name` field); see Bridge mode specifics.

Syntax

```
bridge_config:
  piles:
  - name: <pile_name_1>
  - name: <pile_name_2>
  ...
  - name: <pile_name_n>
```

client_certificate_authorization

The `client_certificate_authorization` section configures authentication of database nodes within the YDB cluster using client certificates. This ensures that service connections between cluster nodes are assigned the correct security identifiers, or SIDs. The process applies to connections that use the gRPC protocol for registering nodes in the cluster and accessing configuration information.

Node authentication settings are configured within the static configuration of the cluster.

The `client_certificate_authorization` section specifies the authentication settings for database node connections by defining the requirements for the content of the "Subject" and "Subject Alternative Name" fields in node certificates, as well as the list of SID values assigned to the connections.

The "Subject" field of the node certificate may contain multiple components (such as `O` – organization, `OU` – organizational unit, `C` – country, `CN` – common name), and checks can be configured against one or more of these components.

The "Subject Alternative Name" field of the node certificate is a list of the node's network names or IP addresses. Checks can be configured to match the names specified in the certificate against the expected values.

Syntax

```
client_certificate_authorization:
  request_client_certificate: Bool
  default_group: <default SID>
  client_certificate_definitions:
    - member_groups: <SID array>
      require_same_issuer: Bool
      subject_dns:
        suffixes: <array of allowed suffixes>
        values: <array of allowed values>
      subject_terms:
      - short_name: <Subject Name component>
        suffixes: <array of allowed suffixes>
        values: <array of allowed values>
    - member_groups: <SID array>
    ...
```

Key	Description
`request_client_certificate`	Request a valid client certificate for node connections. Allowed values: • `false` — A certificate is not required (used by default if the parameter is omitted). • `true` — A certificate is required for all node connections.
`default_group`	SID assigned to all connections providing a trusted client certificate when no explicit settings are provided in the `client_certificate_definitions` section.
`client_certificate_definitions`	Section defining the requirements for database node certificates.
`member_groups`	SIDs assigned to connections that conform to the requirements of the current configuration block.
`require_same_issuer`	Require that the value of the "Issuer" field (typically containing the Certification Authority name) is the same for both client (database node) and server (storage node) certificates. Allowed values: • `true` — The values must be the same (used by default if the parameter is omitted). • `false` — The values can be different (allowing client and server certificates to be issued by different Certification Authorities).
`subject_dns`	Allowed values for the "Subject Alternative Name" field, specified as either full values (using the `values` sub-key) or suffixes (using the `suffixes` sub-key). The check is successful if the actual value matches any full name or any suffix specified.
`subject_terms`	Requirements for the "Subject" field value. Contains the component name (in the `short_name` sub-key) and a list of full values (using the `values` sub-key) or suffixes (using the `suffixes` sub-key). The check is successful if the actual value of each component matches either an allowed full value or an allowed suffix.

Examples

The following configuration fragment enables node authentication and requires the "Subject" field to include the component `O=YDB`. Upon successful authentication, the connection is assigned the `registerNode@cert` SID.

```
client_certificate_authorization:
  request_client_certificate: true
  client_certificate_definitions:
    - member_groups: ["registerNode@cert"]
      subject_terms:
      - short_name: "O"
        values: ["YDB"]
```

The next configuration fragment enables node authentication, and requires "Subject" field to include both `OU=cluster1` and `O=YDB` components. In addition "Subject Alternative Name" field should contain the network name ending with the `.cluster1.ydb.company.net` suffix. Upon successful authentication, the connection will be assigned the `registerNode@cert` SID.

```
client_certificate_authorization:
  request_client_certificate: true
  client_certificate_definitions:
    - member_groups: ["registerNode@cert"]
      subject_dns:
        suffixes: [".cluster1.ydb.company.net"]
      subject_terms:
      - short_name: "OU"
        values: ["cluster1"]
      - short_name: "O"
        values: ["YDB"]
```

cms_config

Cluster Management System (CMS) is a YDB component that enables safe cluster maintenance, for example, updating its version or replacing failed disks without loss of availability. CMS behavior is configured in the `cms_config` section of the YDB configuration.

Syntax

```
cms_config:
  tenant_limits:
    disabled_nodes_limit: 2
    disabled_nodes_ratio_limit: 5
  cluster_limits:
    disabled_nodes_limit: 3
    disabled_nodes_ratio_limit: 5
  disable_maintenance: true
```

Parameters

Parameter	Default value	Description
`tenant_limits.disabled_nodes_limit`	—	Maximum number of database nodes that can be simultaneously unavailable or blocked.
`tenant_limits.disabled_nodes_ratio_limit`	`13`	Maximum percentage of database nodes that can be simultaneously unavailable or blocked.
`cluster_limits.disabled_nodes_limit`	—	Maximum number of cluster nodes that can be simultaneously unavailable or blocked.
`cluster_limits.disabled_nodes_ratio_limit`	`13`	Maximum percentage of cluster nodes that can be simultaneously unavailable.
`disable_maintenance`	`false`	Flag that suspends new cluster maintenance operations.

domains_config

This section contains the configuration of the YDB cluster root domain, including the Blob Storage (binary object storage) and State Storage configurations.

> **Note**
>
> Not required for clusters with automatic configuration of State Storage and static groups.

Syntax

```
domains_config:
  domain:
  - name: <root domain name>
    storage_pool_types: <Blob Storage configuration>
  state_storage: <State Storage configuration>
  security_config: <authentication configuration>
```

> **Note**
>
> Formally, the `domain` field can contain many elements as it is a list. However, only the first element is meaningful; the rest will be ignored (there can only be one "domain" in a cluster).

Blob Storage Configuration

> **Note**
>
> Not required for clusters with automatic configuration of State Storage and static groups.

This section defines one or more types of storage pools available in the cluster for database data with the following configuration options:

- Storage pool name
- Device properties (for example, disk type)
- Data encryption (on/off)
- Fault tolerance mode

The following fault tolerance modes are available:

Mode	Description
`none`	There is no redundancy. Applies for testing.
`block-4-2`	Redundancy factor of 1.5, applies to single data center clusters.
`mirror-3-dc`	Redundancy factor of 3, applies to multi-data center clusters.

Syntax

```
  storage_pool_types:
  - kind: <storage pool name>
    pool_config:
      box_id: 1
      encryption_mode: <optional, specify 1 to encrypt data on the disk>
      erasure_species: <fault tolerance mode name - none, block-4-2, or mirror-3-dc>
      kind: <storage pool name - specify the same value as above>
      pdisk_filter:
      - property:
        - type: <device type to be compared with the one specified in host_configs.drive.type>
      vdisk_kind: Default
  - kind: <storage pool name>
  ...
```

Each database in the cluster is assigned at least one of the available storage pools selected in the database creation operation. The names of storage pools among those assigned can be used in the `DATA` attribute when defining column groups in YQL operators `CREATE TABLE` / `ALTER TABLE`.

State Storage Configuration

> **Note**
>
> Not required for clusters with automatic configuration of State Storage and static groups.

State Storage is an independent in-memory storage for variable data that supports internal YDB processes. It stores data replicas on multiple assigned nodes.

State Storage usually does not need scaling for better performance, so the number of nodes in it must be kept as small as possible taking into account the required level of fault tolerance.

State Storage availability is key for a YDB cluster because it affects all databases, regardless of which storage pools they use. To ensure fault tolerance of State Storage, its nodes must be selected to guarantee a working majority in case of expected failures.

The following guidelines can be used to select State Storage nodes:

Cluster type	Min number of nodes	Selection guidelines
Without fault tolerance	1	Select one random node.
Within a single availability zone	5	Select five nodes in different block-4-2 storage pool failure domains to ensure that a majority of 3 working nodes (out of 5) remain when two domains fail.
Geo-distributed	9	Select three nodes in different failure domains within each of the three mirror-3-dc storage pool availability zones to ensure that a majority of 5 working nodes (out of 9) remain when the availability zone + failure domain fail.

When deploying State Storage on clusters that use multiple storage pools with a possible combination of fault tolerance modes, consider increasing the number of nodes and spreading them across different storage pools because unavailability of State Storage results in unavailability of the entire cluster.

Syntax

```
state_storage:
- ring:
    node: <StateStorage node array>
    nto_select: <number of data replicas in StateStorage>
  ssid: 1
```

Each State Storage client (for example, DataShard tablet) uses `nto_select` nodes to write copies of its data to State Storage. If State Storage consists of more than `nto_select` nodes, different nodes can be used for different clients, so you must ensure that any subset of `nto_select` nodes within State Storage meets the fault tolerance criteria.

Odd numbers must be used for `nto_select` because using even numbers does not improve fault tolerance in comparison to the nearest smaller odd number.

Complete Configuration Examples

Single Data Center with `block-4-2` Erasure

```
domains_config:
  domain:
  - name: Root
    storage_pool_types:
    - kind: ssd
      pool_config:
        box_id: 1
        erasure_species: block-4-2
        kind: ssd
        pdisk_filter:
        - property:
          - type: SSD
        vdisk_kind: Default
  state_storage:
  - ring:
      node: [1, 2, 3, 4, 5, 6, 7, 8]
      nto_select: 5
    ssid: 1
```

Multi Data Center with `mirror-3-dc` Erasure

```
domains_config:
  domain:
  - name: global
    storage_pool_types:
    - kind: ssd
      pool_config:
        box_id: 1
        erasure_species: mirror-3-dc
        kind: ssd
        pdisk_filter:
        - property:
          - type: SSD
        vdisk_kind: Default
  state_storage:
  - ring:
      node: [1, 2, 3, 4, 5, 6, 7, 8, 9]
      nto_select: 9
    ssid: 1
```

No Fault Tolerance (`none`) - For Testing

```
domains_config:
  domain:
  - name: Root
    storage_pool_types:
    - kind: ssd
      pool_config:
        box_id: 1
        erasure_species: none
        kind: ssd
        pdisk_filter:
        - property:
          - type: SSD
        vdisk_kind: Default
  state_storage:
  - ring:
      node: [1]
      nto_select: 1
    ssid: 1
```

Multiple Storage Pool Types

```
domains_config:
  domain:
  - name: Root
    storage_pool_types:
    - kind: ssd
      pool_config:
        box_id: '1'
        erasure_species: block-4-2
        kind: ssd
        pdisk_filter:
        - property:
          - {type: SSD}
        vdisk_kind: Default
    - kind: rot
      pool_config:
        box_id: '1'
        erasure_species: block-4-2
        kind: rot
        pdisk_filter:
        - property:
          - {type: ROT}
        vdisk_kind: Default
    - kind: rotencrypted
      pool_config:
        box_id: '1'
        encryption_mode: 1
        erasure_species: block-4-2
        kind: rotencrypted
        pdisk_filter:
        - property:
          - {type: ROT}
        vdisk_kind: Default
    - kind: ssdencrypted
      pool_config:
        box_id: '1'
        encryption_mode: 1
        erasure_species: block-4-2
        kind: ssdencrypted
        pdisk_filter:
        - property:
          - {type: SSD}
        vdisk_kind: Default
  state_storage:
  - ring:
      node: [1, 16, 31, 46, 61, 76, 91, 106]
      nto_select: 5
    ssid: 1
```

feature_flags

YDB implements feature flags following the established feature toggling approach.

Feature flags are settings that enable or disable individual YDB capabilities. They allow new functionality to be enabled gradually: its code may already be present in the installed YDB version while the functionality itself is still unavailable to users.

Who Changes Feature Flags

Feature flags can be changed by the feature owner, who understands its internal implementation. Changing a flag is a complex process: it requires considering the cluster state, dependencies between capabilities, and compatibility between versions and data formats.

Do not change flags yourself if you do not have sufficient knowledge of the feature's internal implementation and the consequences of changing its state. Before changing a flag, read the documentation for your YDB version and, if necessary, discuss the change with the feature owner.

> **Warning**
>
> Enabling a flag may affect data compatibility and prevent rolling YDB back to a previous version. Such a rollback may be necessary if a critical error is discovered after an upgrade.

Experimental Functionality

Why a Flag May Be Disabled

Some functionality is included in a release in an experimental state. It is still under development and is therefore disabled by default. Its behavior, syntax, API, or data storage format may change without backward compatibility. Such functionality may remain experimental for a long time or be removed without ever becoming generally available.

However, not every disabled flag indicates experimental functionality. Some flags control stable capabilities that not everyone needs. Check the status of a particular capability in the documentation for the relevant YDB version.

A capability being described in the documentation or its code being included in a release does not necessarily mean that it is enabled on your database's cluster.

Risks of Enabling Experimental Functionality

Stability, performance, and backward compatibility are not guaranteed for experimental functionality. Enabling its flag may lead to:

- errors when executing queries or cluster instability;
- reduced performance;
- data being written in a format that the previous YDB version does not support.

In the last case, disabling the flag does not necessarily restore the previous data format. You should therefore assess whether a version rollback is possible before enabling the functionality, rather than after a problem occurs.

Do not enable experimental functionality in production clusters. Use a separate test cluster with data you can afford to lose.

How to Check Whether Functionality Is Available

When checking availability, consider the installed YDB version and the cluster configuration.

1. Read the documentation and release notes for the relevant version. Check the functionality's limitations and any indication of its experimental status.
2. Generate the final configuration for the nodes that serve the target database and check the corresponding flag's value. Flag descriptions are provided in the configuration reference.

The default flag value is determined by the code of the corresponding YDB version. The value in the cluster configuration may differ from the default. The flag reference therefore does not replace checking actual availability on your cluster.

How Functionality Becomes Generally Available

When experimental functionality is ready for general use, its flag is enabled by default in the corresponding YDB version. The experimental status warning is removed from that version's documentation, and the release notes announce the functionality's availability.

After upgrading the cluster, check its configuration: an explicitly set flag value may differ from the new default.

Configuring Flags

The `feature_flags` section enables or disables certain YDB features in the main cluster configuration. With dynamic configuration selectors, you can override flags for individual databases or node groups. To enable a feature, set the corresponding feature flag to `true`. For example, to enable auto-partitioning of topics in CDC, add the following lines to the configuration:

```
feature_flags:
  enable_topic_autopartitioning_for_cdc: true
```

Feature Flags

Flag	Function
`enable_json_index`	JSON indexes to speed up search in JSON fields
`enable_json_index_auto_select`	Automatic selection of JSON indexes when executing queries
`enable_fulltext_index`	Full-text index for full-text search
`enable_local_bloom_filter_index`	Local Bloom index of type `bloom_filter`
`enable_local_bloom_ngram_filter_index`	Local Bloom index of type `bloom_ngram_filter`

`enable_topic_autopartitioning_for_cdc`	Auto-partitioning of topics in CDC for row tables
`enable_access_to_index_impl_tables`	Ability to specify the number of replicas for a secondary index
`enable_changefeeds_export`, `enable_changefeeds_import`	Support for change feeds (changefeed) in backup and restore operations
`enable_view_export`	Support for views (`VIEW`) in backup and restore operations
`enable_export_auto_dropping`	Auto-deletion of temporary directories and tables when exporting to S3
`enable_followers_stats`	System views with information about history of overloaded partitions
`enable_strict_acl_check`	Prohibition on granting permissions to non-existent users and on deleting users who have been granted permissions
`enable_strict_user_management`	Strict rules for administering local users (i.e., only the cluster or database administrator can administer local users)
`enable_database_admin`	Adding the database administrator role
`enable_kafka_native_balancing`	Client-side partition balancing when reading via Kafka protocol
`enable_topic_compactification_by_key`	Enabling topic compaction in YDB Topics Kafka API
`enable_kafka_transactions`	Enabling transactions in YDB Topics Kafka API
`enable_external_data_sources`	Enabling external data sources
`enable_grpc_audit`	Enabling audit of gRPC connection state changes
`enable_fs_backups`	Enabling backup and restore operations to a network file system
`switch_to_config_v2`	Switching from configuration V1 to configuration V2
`enable_streaming_queries`	Enabling streaming queries
`enable_stable_node_names`	Enabling stable names for dynamic nodes
`enable_alter_database_create_hive_first`	Creating a dedicated Hive for a database's system tablets when the database is created

query_service_config

The `query_service_config` section describes the parameters for YDB to work with external data sources using federated queries.

If access to the required source requires deploying a connector, it must also be configured according to the instructions.

Parameter description

Parameter	Default value	Description
`generic.connector.endpoint.host`	`localhost`	Connector host name.
`generic.connector.endpoint.port`	`2130`	Connector TCP port.
`generic.connector.use_ssl`	`false`	Whether to use connection encryption. When the connector and YDB dynamic node are deployed on the same server, encrypted connection between them is not required, but it can be enabled if needed.
`generic.connector.ssl_ca_crt`	empty string	Path to the CA certificate used for encryption.
`generic.default_settings.name.UsePredicatePushdown`	`false`	Enables predicate pushdown to external data sources: some parts of SQL queries (for example, filters) will be passed for execution to the external source. This can significantly reduce the volume of data transferred over the network from the data source to federated YDB, save its computational resources, and significantly reduce federated query processing time.
`available_external_data_sources`	empty list	List of allowed external data source types. Applied when `all_external_data_sources_are_available: false`. Possible values: • `ObjectStorage`; • `ClickHouse`; • `PostgreSQL`; • `MySQL`; • `Greenplum`; • `MsSQLServer`; • `Ydb`.
`all_external_data_sources_are_available`	`false`	Enable all external data source types. When enabled, the `available_external_data_sources` setting is ignored.

Examples

Enabling ClickHouse and MySQL external sources

```
query_service_config:
  generic:
    connector:
      endpoint:
        host: localhost                  # host name where the connector is deployed
        port: 2130                       # connector port number
      use_ssl: false                     # flag to enable connection encryption
      ssl_ca_crt: "/opt/ydb/certs/ca.crt" # path to CA certificate
    default_settings:
    - name: UsePredicatePushdown
      value: "true"
  all_external_data_sources_are_available: false
  available_external_data_sources:
  - ClickHouse
  - MySQL
```

Enabling all external data source types

```
query_service_config:
  generic:
    connector:
      endpoint:
        host: localhost                  # host name where the connector is deployed
        port: 2130                       # connector port number
      use_ssl: false                     # flag to enable connection encryption
      ssl_ca_crt: "/opt/ydb/certs/ca.crt" # path to CA certificate
    default_settings:
    - name: UsePredicatePushdown
      value: "true"
  all_external_data_sources_are_available: true
```

- Deploying YDB with Federated Query functionality

healthcheck_config

The `healthcheck_config` section configures thresholds and timeout settings used by the YDB health check service. These parameters help configure detection of potential issues, such as excessive restarts or time drift between dynamic nodes.

Syntax

```
healthcheck_config:
  thresholds:
    node_restarts_yellow: 10
    node_restarts_orange: 30
    nodes_time_difference_yellow: 5000
    nodes_time_difference_orange: 25000
    tablets_restarts_orange: 30
  timeout: 20000
```

Parameters

Parameter	Default	Description
`thresholds.node_restarts_yellow`	`10`	Number of node restarts to trigger a `YELLOW` warning
`thresholds.node_restarts_orange`	`30`	Number of node restarts to trigger an `ORANGE` alert
`thresholds.nodes_time_difference_yellow`	`5000`	Max allowed time difference (in us) between dynamic nodes for `YELLOW` issue
`thresholds.nodes_time_difference_orange`	`25000`	Max allowed time difference (in us) between dynamic nodes for `ORANGE` issue
`thresholds.tablets_restarts_orange`	`30`	Number of tablet restarts to trigger an `ORANGE` alert
`timeout`	`20000`	Maximum health check response time (in ms)

host_configs

A YDB cluster consists of multiple nodes, and one or more typical server configurations are usually used for their deployment. To avoid repeating their description for each node, there is a `host_configs` section in the configuration file that lists the used configurations and assigned IDs.

Syntax

```
host_configs:
- host_config_id: 1
  drive:
  - path: <path_to_device>
    type: <type>
  - path: ...
- host_config_id: 2
  ...
```

The `host_config_id` attribute specifies a numeric configuration ID. The `drive` attribute contains a collection of descriptions of connected drives. Each description consists of two attributes:

- `path` : Path to the mounted block device, for example, `/dev/disk/by-partlabel/ydb_disk_ssd_01`
- `type` : Type of the device's physical media: `ssd` , `nvme` , or `rot` (rotational - HDD)

Examples

One configuration with ID 1 and one SSD disk accessible via `/dev/disk/by-partlabel/ydb_disk_ssd_01` :

```
host_configs:
- host_config_id: 1
  drive:
  - path: /dev/disk/by-partlabel/ydb_disk_ssd_01
    type: SSD
```

Two configurations with IDs 1 (two SSD disks) and 2 (three SSD disks):

```
host_configs:
- host_config_id: 1
  drive:
  - path: /dev/disk/by-partlabel/ydb_disk_ssd_01
    type: SSD
  - path: /dev/disk/by-partlabel/ydb_disk_ssd_02
    type: SSD
- host_config_id: 2
  drive:
  - path: /dev/disk/by-partlabel/ydb_disk_ssd_01
    type: SSD
  - path: /dev/disk/by-partlabel/ydb_disk_ssd_02
    type: SSD
  - path: /dev/disk/by-partlabel/ydb_disk_ssd_03
    type: SSD
```

Kubernetes Features

The YDB Kubernetes operator mounts NBS disks for Storage nodes at the path `/dev/kikimr_ssd_00` . To use them, the following `host_configs` configuration must be specified:

```
host_configs:
- host_config_id: 1
  drive:
  - path: /dev/kikimr_ssd_00
    type: SSD
```

The example configuration files provided with the YDB Kubernetes operator contain this section, and it does not need to be changed.

hosts

Configuration

This group lists the static cluster nodes on which the Storage processes run and specifies their main characteristics:

- Numeric node ID
- DNS host name and port that can be used to connect to a node on the IP network
- ID of the standard host configuration
- Placement in a specific availability zone, rack
- Server inventory number (optional)

Syntax

```
hosts:
- host: <DNS host name>
  host_config_id: <numeric ID of the standard host configuration>
  port: <port> # 19001 by default
  location:
    unit: <string with the server serial number>
    data_center: <string with the availability zone ID>
    rack: <string with the rack ID>
- host: <DNS host name>
  ...
```

Examples

```
hosts:
- host: hostname1
  host_config_id: 1
  node_id: 1
  port: 19001
  location:
    unit: '1'
    data_center: '1'
    rack: '1'
- host: hostname2
  host_config_id: 1
  node_id: 2
  port: 19001
  location:
    unit: '1'
    data_center: '1'
    rack: '1'
```

Bridge mode specifics

In bridge mode, each host must be bound to one of the piles declared in `bridge_config`. Add `bridge_pile_name` under `location` with the pile name. Example:

```
hosts:
- host: hostname1
  host_config_id: 1
  location:
    unit: '1'
    data_center: '1'
    rack: '1'
    bridge_pile_name: 'pile_1'
```

Kubernetes-Specific Details

When deploying YDB with a Kubernetes operator, the entire `hosts` section is generated automatically, replacing any user-specified content in the configuration passed to the operator. All Storage nodes use `host_config_id` = `1`, for which the correct configuration must be specified.

immediate_controls_config

The `immediate_controls_config` section provides a set of dynamic parameters for fine-tuning YDB components, including DataShard, Coordinator, SchemeShard, BlobStorage, and others. These settings let you adapt cluster behavior to specific scenarios — for example, by configuring thresholds for automatic shard splitting as data grows or load increases.

Syntax

```
immediate_controls_config:
  ...
  scheme_shard_controls:
    force_shard_split_data_size: 2147483648
    ...
```

Parameters

Parameter	Minimum value	Maximum value	Default value	Description
`scheme_shard_controls.force_shard_split_data_size`	10 MiB	16 GiB	2 GiB	A table partition is forcibly split when it reaches the specified data size, even if the table's partition size threshold or maximum partition count would otherwise prevent the split. Specify the value in bytes.

log_config

The `log_config` section controls how the YDB server process handles and manages its logs. It allows you to configure logging levels for various components, as well as global log formats and output methods.

> **Note**
>
> This document describes application and system logging configuration. For information on logging for audit and security purposes, see Audit log.

Overview

Logging is a critical part of the YDB observability system. The `log_config` section allows you to configure various aspects of logging, including:

- default logging level;
- logging levels for specific components;
- log output format;
- integration with syslog or external logging services.

Log Output Methods

- **To stderr**: by default, YDB sends all logs to stderr.
- **To file**: logs can be written to a file using the `backend_file_name` parameter.
- **To syslog**: when the `sys_log: true` parameter is enabled, logs are redirected to the system syslog and stop being output to stderr. Logs are sent using the `/dev/log` socket.
- **To Unified Agent**: when configuring the `uaclient_config` section, logs are sent to Unified Agent and stop being output to stderr.

When both `sys_log` and `uaclient_config` are enabled simultaneously, logs will be sent to both syslog and Unified Agent. If you need to continue outputting logs to stderr while using other methods, activate `sys_log_to_stderr: true`.

Configuration Options

Parameter	Type	Default	Description
`default_level`	uint32	5 (`NOTICE`)	Default logging level for all components.
`default_sampling_level`	uint32	7 (`DEBUG`)	Default sampling level for all components.
`default_sampling_rate`	uint32	0	Default sampling rate for all components. If set to N (where N > 0), approximately 1 out of every N log messages with priority between `default_level` and `default_sampling_level` will be logged. For example, to log every 10th message, set to 10. A value of 0 means that messages in this range will not be logged (all of them are dropped).
`sys_log`	bool	false	Enable logging via syslog.
`sys_log_to_stderr`	bool	false	Copy logs to stderr in addition to syslog.
`format`	string	"full"	Log output format. Possible values: "full", "short", "json".
`cluster_name`	string	—	Cluster name to include in log records. The `cluster_name` field is added to logs only when using the `json` format or when sending to Unified Agent. In the `full` or `short` formats, this field is not displayed.
`allow_drop_entries`	bool	true	Allow dropping log entries if the logging system is overloaded. When this option is enabled, log entries are buffered in memory and written to the output when 10 messages accumulate or the time specified in `time_threshold_ms` elapses. If the buffer becomes full, low-priority messages may be dropped to make room for higher-priority messages.
`use_local_timestamps`	bool	false	Use local time zone for log timestamps (UTC is used by default).
`backend_file_name`	string	—	File name for log output. If specified, logs are written to this file.
`sys_log_service`	string	—	Service name for syslog. Corresponds to the tag field in the old syslog protocol RFC 3164 or the app-name field in the modern protocol RFC 5424.
`time_threshold_ms`	uint64	1000	If `allow_drop_entries = true`, specifies how often, in milliseconds, YDB writes buffered log entries to the output.
`ignore_unknown_components`	bool	true	Ignore logging requests from unknown components.
`entry`	array	[]	Configuration of logging level and/or sampling for specific YDB components, see Entry Objects below.
`uaclient_config`	object	—	Configuration for the Unified Agent client, see UAClientConfig Object below.

`enable_structured_log_in_json`	bool	false	When outputting the log in `json` format: if `false`, the message text (the `message` field) contains structured values as `key=value` (for example, `Text (a=1 b=2)`); if `true`, the `message` field contains only the text, and structured values are output as separate string JSON fields (for example, `{"message":"Text","a":"1","b":"2"}`). Reserved field names get the `_` prefix.

Entry Objects

> **Note**
>
> Logging in YDB assumes that the system consists of a large number of internal components, each of which has its own unique code assigned. You can find the full list of components and their codes on GitHub.
>
> When writing a message to the log, the component code on whose behalf the message is written must be explicitly or implicitly specified. Subsequently, the component name is output to the log and can be used to search or filter log content.

The `entry` field allows you to set logging parameters for individual components. It contains an array of objects with the following structure:

Parameter	Type	Description
`component`	string	Component name. See the full list of available components on GitHub.
`level`	uint32	Log level for this component.
`sampling_level`	uint32	Sampling level for this component. Works similarly to `default_sampling_level`.
`sampling_rate`	uint32	Sampling rate for this component. Works similarly to `default_sampling_rate`.

UAClientConfig Object

The `uaclient_config` field configures integration with Unified Agent:

Parameter	Type	Default	Description
`uri`	string	—	grpc URI of the Unified Agent server.
`shared_secret_key`	string	—	Path to the file with the secret key for authenticating client connections.
`max_inflight_bytes`	uint64	100000000	Maximum number of bytes in transit when sending data.
`grpc_reconnect_delay_ms`	uint64	—	Delay between reconnection attempts in milliseconds.
`grpc_send_delay_ms`	uint64	—	Delay between send attempts in milliseconds.
`grpc_max_message_size`	uint64	—	Maximum gRPC message size.
`client_log_file`	string	—	Log file for the UA client itself.
`client_log_priority`	uint32	—	Logging level for the UA client itself.
`log_name`	string	—	Log name that is passed in session metadata.

Log Levels

YDB uses the following log levels, listed from the highest to the lowest severity:

Level	Numeric value	Description
`EMERG`	0	System failure is possible (for example, cluster failure).
`ALERT`	1	System degradation is possible, system components may fail.
`CRIT`	2	Critical state.
`ERROR`	3	Non-critical error.
`WARN`	4	A warning that should be responded to and fixed unless it is temporary.
`NOTICE`	5	An event essential for the system or the user has occurred.
`INFO`	6	Debugging information for collecting statistics.
`DEBUG`	7	Debugging information for developers.
`TRACE`	8	Very detailed debugging information.

Examples

Basic Configuration

```
log_config:
  default_level: 5  # NOTICE
  format: "full"
```

This configuration outputs logs to stderr with logging level `NOTICE` and above.

Configuration with File Output

```
log_config:
  default_level: 5  # NOTICE
  format: "full"
  backend_file_name: "/var/log/ydb/ydb.log"
```

This configuration sends logs to a file while maintaining the default logging level of `NOTICE`.

Configuration with Syslog Output

```
log_config:
  default_level: 5  # NOTICE
  sys_log: true
  sys_log_service: "ydb"
  format: "full"
```

This configuration sends logs to syslog with the service name "ydb".

Setting Log Levels for Individual Components

```
log_config:
  default_level: 5  # NOTICE
  entry:
    - component: "SCHEMESHARD"
      level: 7  # DEBUG
    - component: "TABLET_MAIN"
      level: 6  # INFO
  backend_file_name: "/var/log/ydb/ydb.log"
```

Enabling Transaction Lock Invalidation Diagnostics (TLI)

To diagnose `transaction locks invalidated` errors, enable logging for the `TLI` component:

```
log_config:
  entry:
    - component: "TLI"
      level: 6  # INFO
```

Once enabled, the server writes logs on every lock conflict, including identifiers and query texts of both victims and violators. For details on the log entry format, event correlation, and the `find_tli_chain` utility, see TLI Logging.

Sampling Configuration

```
log_config:
  default_level: 5  # NOTICE
  default_sampling_level: 7  # DEBUG
  default_sampling_rate: 10  # Log every 10th message between NOTICE and DEBUG
  entry:
    - component: "BLOBSTORAGE"
      sampling_level: 8  # TRACE
      sampling_rate: 100  # Log every 100th message between NOTICE and TRACE
```

This configuration sets up log sampling. With default settings, every 10th message with priority between `NOTICE` and `DEBUG` will be logged. For the `BLOBSTORAGE` component, every 100th message with priority between `NOTICE` and `TRACE` will be logged.

JSON Format Configuration

```
log_config:
  default_level: 5  # NOTICE
  format: "json"
  cluster_name: "production-cluster"
  uaclient_config:
    uri: "[fd53::1]:16400"
    grpc_max_message_size: 4194304
    log_name: "ydb_logs"
```

This configuration outputs logs in JSON format and sends them to Unified Agent.

Notes

- Log levels are specified in the configuration as numeric values, not strings. Use the table above to map between numeric values and their meanings.
- If the `backend_file_name` parameter is specified, logs are written to this file. If the `sys_log` parameter is true, logs are sent to the system logger.
- The `format` parameter determines how log entries are formatted. The "full" format includes all available information, "short" provides a more compact format, and "json" outputs logs in JSON format, which is convenient for parsing by logging services.
- The internal log buffer has the following size limits:
  - Default total size: 10MB (10 * 1024 * 1024 bytes)
  - Default grain size: 64KB (1024 * 64 bytes)
  - Maximum message size: 1KB (1024 bytes)

memory_controller_config

Inside nodes, YDB runs many different components that use memory. Most of them require a fixed amount of memory, but some can flexibly vary the amount of memory they use, thereby improving the performance of the entire system.

Overview of memory consumption inside a YDB node by component

If YDB components allocate more memory than is physically available, the operating system will likely terminate the entire YDB process, which is highly undesirable. The goal of the memory controller is to allow YDB to avoid out-of-memory situations while efficiently using the available memory.

Examples of components managed by the memory controller:

- Shared cache: stores recently accessed data pages read from distributed storage to reduce disk I/O operations and speed up data retrieval.
- MemTable: contains data that has not yet been written to SST.
- Query Processor: stores intermediate query processing results.
- Compaction: the process of ordering and cleaning data that runs automatically (in the background) to optimize storage volume.
- Allocator caches: store memory blocks that have been freed but not yet returned to the operating system.

Memory limits can be configured to control overall memory usage, ensuring efficient database operation within available resources.

Hard memory limit

The hard memory limit defines the total amount of memory available to the YDB process.

By default, the hard memory limit for the YDB process equals the memory limit specified in its cgroups.

In environments without a cgroups memory limit, the default hard memory limit equals the total amount of available host memory. This configuration allows the database to use all available resources but may lead to resource contention with other processes on the same host. Although the memory controller tries to account for this external consumption, such usage is not recommended.

The hard memory limit can also be set in the configuration. Note that the database process may still exceed this limit. Therefore, it is strongly recommended to use cgroups memory limits in production environments for strict memory control.

Most other memory limits can be configured either in absolute bytes or as percentages relative to the hard memory limit. Using percentages is convenient for managing clusters with nodes of different capacities. If both absolute byte limits and percentage limits are specified, the memory controller uses a combination of both (maximum for lower limits and minimum for upper limits).

Example of a `memory_controller_config` section with a specified hard memory limit:

```
memory_controller_config:
  hard_limit_bytes: 16106127360
```

Soft memory limit

The soft memory limit defines a dangerous threshold that the YDB process should not exceed under normal circumstances.

If the soft limit is exceeded, YDB gradually reduces the size of the shared cache to zero. In this case, you should add more database nodes to the cluster or reduce memory limits for individual components as soon as possible.

Target memory usage

Target memory usage defines a memory usage threshold for the YDB process that is considered optimal.

Flexible cache sizes are calculated according to their limits to keep the process memory consumption near this value.

For example, in a database that uses little memory for query execution, caches use memory near this threshold, and the remaining memory stays free. If query execution starts consuming more memory, caches begin to reduce their sizes to the minimum threshold.

Memory limits for individual components

Inside YDB, there are two different types of components.

The first type of components, or cache components, function as caches, for example, storing recently used data. Each cache component has minimum and maximum threshold values for the memory limit, allowing it to dynamically adjust its capacity based on the current memory consumption of the YDB process.

The second type of components, or activity components, allocate memory for specific tasks, such as executing queries or the compaction process. Each activity component has a fixed memory limit. There is also an additional shared memory limit for such components, from which they attempt to obtain the necessary memory.

Many other auxiliary components and processes run in parallel with the YDB process, consuming memory. Currently, these components do not have any memory limits.

Memory limits for cache components

Cache components include:

- Shared cache.
- MemTable.

The limits of each cache component are dynamically recalculated every second, so that each component consumes memory proportionally to its limit values, and the total memory consumption remains around the target memory usage.

The minimum threshold of the memory limit for cache components is not reserved, meaning that memory remains available until it is actually used. However, once this memory is filled, components typically retain data, operating within their current memory limit. Thus, the sum of the minimum memory limits of cache components is expected to be less than the target memory usage.

If necessary, both minimum and maximum threshold values should be overridden; otherwise, if a threshold value is missing, it will take the default value.

Example of the `memory_controller_config` section with specified shared cache limits:

```
memory_controller_config:
  shared_cache_min_percent: 10
  shared_cache_max_percent: 30
```

Memory limits for activity components

Activity components include:

- Query Processor.
- Compaction.

The memory limit for each activity component specifies the maximum amount of memory it can attempt to use. However, to prevent the YDB process from exceeding the soft memory limit, the total consumption of activity components is limited by an additional limit called the activity memory limit. If the total memory usage of active components exceeds this limit, any additional memory requests will be denied. When query execution approaches the memory limits, YDB activates spilling to temporarily save intermediate data to disk, preventing memory limit violations.

Thus, although the total individual limits of activity components may collectively exceed the activity memory limit, the individual limit of each component must be less than this overall limit. Additionally, the sum of the minimum memory limits for cache components plus the activity memory limit must be less than the soft memory limit.

There are other activity components that currently do not have any individual memory limits.

Example of the `memory_controller_config` section with the specified limit for QP:

```
memory_controller_config:
  query_execution_limit_percent: 25
```

Query Processor memory limit

The `query_execution_limit_percent` (default 20% of the hard memory limit) and `query_execution_limit_bytes` parameters set the size of the RAM pool that Resource Manager allocates to queries on a node:

If both parameters are set, the effective limit is `min(query_execution_limit_percent × hard_limit_bytes / 100, query_execution_limit_bytes)`. If only one parameter is set, its value is used.

The computed limit is passed to Resource Manager via Resource Broker.

The `spilling_percent` threshold in `table_service_config` is calculated relative to this pool.

Configuration parameters

Each configuration parameter applies in the context of a single database node.

As mentioned earlier, the sum of the minimum memory limits for cache components plus the activity memory limit is expected to be less than the soft memory limit.

This constraint can be expressed in a simplified form:

Or in a detailed form:

Parameters	Default value	Description
`hard_limit_bytes`	CGroup memory limit / Host memory	Hard limit for memory usage.
`soft_limit_percent` / `soft_limit_bytes`	75%	Soft limit for memory usage.
`target_utilization_percent` / `target_utilization_bytes`	50%	Target memory usage.
`activities_limit_percent` / `activities_limit_bytes`	30%	Memory limit for activities.
`shared_cache_min_percent` / `shared_cache_min_bytes`	20%	Minimum threshold for the shared cache memory limit.
`shared_cache_max_percent` / `shared_cache_max_bytes`	50%	Maximum threshold for the shared cache memory limit.
`mem_table_min_percent` / `mem_table_min_bytes`	1%	Minimum threshold for the MemTable memory limit.

`mem_table_max_percent` / `mem_table_max_bytes`	3%	Maximum threshold for the MemTable memory limit.
`query_execution_limit_percent` / `query_execution_limit_bytes`	20%	Memory limit for QP.
`compaction_limit_percent` / `compaction_limit_bytes`	10%	Memory limit for compaction.

node_broker_config

Configuration

The `node_broker_config` section configures stable node names for dynamic nodes in YDB clusters. Node names are assigned through the Node Broker, which is a system tablet that registers dynamic nodes in the cluster.

Node Broker assigns names to dynamic nodes when they register in the cluster. By default, a node name consists of the hostname and the port on which the node is running.

In a dynamic environment where hostnames often change, such as in Kubernetes, using hostname and port leads to an uncontrollable increase in the number of unique node names. This is true even for a database with a handful of dynamic nodes. Such behavior may be undesirable for a time series monitoring system as the number of metrics grows uncontrollably. To solve this problem, the system administrator can set up *stable* node names.

A stable name identifies a node within the tenant. It consists of a prefix and a node's sequential number within its tenant. If a dynamic node has been shut down, after a timeout, its stable name can be taken by a new dynamic node serving the same tenant.

To enable stable node names, set the `enable_stable_node_names` feature flag in the cluster configuration:

```
feature_flags:
  enable_stable_node_names: true
```

By default, the prefix is `slot-`. To override the prefix, add the following to the cluster configuration:

```
node_broker_config:
  stable_node_name_prefix: <new prefix>
```

resource_broker_config

Configuration

The resource broker is an actor service that controls resource consumption on YDB nodes, such as:

- `CPU` — number of threads
- `Memory` — RAM

Different types of activities (background operations, TTL data deletion, etc.) run in different resource broker *queues*. Each queue has a limited number of resources:

Queue name	CPU	Memory	Description
`queue_ttl`	2	—	TTL data deletion operations.
`queue_backup`	2	—	Backup operations.
`queue_restore`	10	—	Restore from backup operations.
`queue_build_index`	10	—	Online secondary index creation operations.
`queue_cdc_initial_scan`	2	—	Initial table scan operations.

Note

It is recommended to **extend** the resource broker configuration using tags `!inherit` and `!append`.

Example of extending the resource broker configuration with a custom limit for the `queue_ttl` queue:

```
resource_broker_config: !inherit
  queues: !append
  - name: queue_ttl
    limit:
      cpu: 4
```

security_config

The `security_config` section defines authentication modes, the initial configuration of local users and groups, and their access rights.

```
security_config:
  # authentication mode configuration
  enforce_user_token_requirement: false
  enforce_user_token_check_requirement: false
  default_user_sids: <authentication token for anonymous requests>
  all_authenticated_users: <group name for all authenticated users>
  all_users_group: <group name for all users>

  # initial security configuration
  default_users: <default user list>

Configuring Authentication Mode

Parameter	Description
`enforce_user_token_requirement`	Selects user authentication mode. • `enforce_user_token_requirement: true` — User authentication is mandatory. Requests to YDB must include an auth token. Requests to YDB undergo authentication and authorization. • `enforce_user_token_requirement: false` — User authentication is optional. Requests to YDB are not required to include an auth token. Requests without an auth token are processed in anonymous mode without authorization. Requests with an auth token undergo authentication and authorization. However, requests are still processed in anonymous mode if an authentication error occurs. When `enforce_user_token_check_requirement: true`, requests with authentication errors are blocked. If the `default_user_sids` parameter is defined and not empty (see the description below), its value is used instead of the missing auth token. In this case, authentication and authorization are performed for the access subject defined in `default_user_sids`. Default value: `false`.
`enforce_user_token_check_requirement`	Forbids ignoring authentication errors in the `enforce_user_token_requirement: false` mode. Default value: `false`.
`default_user_sids`	Specifies a list of SIDs for authenticating incoming requests without an auth token. `default_user_sids` acts as an auth token for anonymous requests. The first element in the list must be a user SID. The following elements must be the SIDs of groups to which the user belongs. If the `default_user_sids` list is not empty, mandatory authentication mode (`enforce_user_token_requirement: true`) can be used for anonymous requests. This mode can be used in some YDB testing scenarios or for educational purposes in local YDB installations. Default value: empty.
`all_authenticated_users`	Specifies the name of the virtual group that includes all authenticated users. This virtual group is created automatically by YDB. You cannot delete this virtual group, list its members, or modify them. You can use this group to grant access rights on scheme objects. **Tip** You can get information about access rights on scheme objects in the system views. For more information see, Users, groups, and access rights. Default value: `all-users@well-known`.

`all_users_group`	Specifies the name of the group that includes all local users. If `all_users_group` is not empty, all local users will be added to the group with this name upon creation. The group specified in this parameter must exist when new users are added. The `all_users_group` parameter is used during the initialization of built-in security. Default value: empty.

The following diagram displays the relationship between authentication mode parameters described above:

Bootstrapping Security

The `default_users`, `default_groups`, and `default_access` parameters affect the initial YDB cluster configuration that occurs when YDB starts for the first time. During subsequent runs, the initial configuration is not repeated, and these parameters are ignored.

See Initial cluster security configuration and the related `domains_config` parameters.

Parameter	Description

`default_users`	The list of users to be created when the YDB cluster starts for the first time.
	
	The list consists of login-password pairs. The first user in the list is a superuser.
	
	Warning
	Passwords are specified in plain text, so it is unsafe to use them for an extended period. You must change these passwords in YDB after the first start. For example, use the `ALTER USER` statement.
	
	Example:
	
	`default_users:`
	`- name: root`
	`  password: <...>`
	`- name: user1`
	`  password: <...>`
	
	Errors in the `default_users` list, such as duplicate logins, are logged but do not affect YDB cluster startup.

`default_groups`	The list of groups to be created when the YDB cluster starts for the first time.
	
	The list includes groups and their members.
	
	Warning
	These groups are created for the entire YDB cluster.
	
	Example:
	
	``
	default_groups:
	- name: ADMINS
	  members: root
	- name: USERS
	  members:
	  - ADMINS
	  - root
	  - user1
	``
	
	The order of groups in this list matters: groups are created in the order in which they appear in the `default_groups` parameter. Group members must exist before the group is created. Nonexistent users will not be added to the group.
	
	Failures to add users to groups are logged but do not affect the YDB cluster startup.

`default_access`	The list of access rights to be granted on the cluster scheme root. Access rights are specified using the short access control notation. Example: ``` default_access: - +(CDB|DDB|GAR):ADMINS - +(ConnDB):USERS ``` Errors in access right entries are logged but do not affect YDB cluster startup. Access rights with errors will not be granted.

Configuring Administrative and Other Privileges

Access level lists are configured in the `security_config` section. For detailed information about access level lists, their hierarchy, and how they work, see Access level lists in the Authorization documentation.

Parameter	Description
`database_allowed_sids`	The list of SIDs with the database access level. This level is less privileged than viewer. Subjects can only operate within a database scope — backend calls without a specified database are forbidden. Cluster-level requests (e.g., listing cluster nodes) return 403. Database-scoped requests (e.g., database pages in YDB UI) work normally. Intended for applications or users restricted to a single database.
`viewer_allowed_sids`	The list of SIDs with the viewer access level. This level allows viewing the cluster state, which is not publicly accessible (including most pages in the YDB UI). No changes are allowed.
`monitoring_allowed_sids`	The list of SIDs with the monitoring access level. This level grants additional privileges to monitor and modify the cluster state. For example, it allows performing a backup, restoring a database, or executing YQL statements in the YDB UI.
`administration_allowed_sids`	The list of SIDs with the administration access level. This level grants privileges to administer the YDB cluster and its databases. Also used for config changes, scheme operations requiring admin privileges, and other administrative checks. An empty list means any user is treated as an administrator.
`bootstrap_allowed_sids`	The list of SIDs that are allowed to perform cluster bootstrap. Used to initially bootstrap the cluster from an uninitialized state (when the auth subsystem is not yet functional). Bootstrap is allowed if the subject is in `bootstrap_allowed_sids` or `administration_allowed_sids`. `bootstrap_allowed_sids` allows specific identities to bootstrap the cluster without granting full administration privileges.
`register_dynamic_node_allowed_sids`	The list of SIDs that are allowed to register database nodes. For technical reasons, this list must include `root@builtin`.

Warning

The access level lists are empty by default.

An **empty** list means "allow any user" — any SID is acceptable (or no SID at all if anonymous access is allowed). Empty `administration_allowed_sids` grants any user administrator privileges; empty `viewer_allowed_sids` (with other UI lists empty) allows any user viewer-level access to YDB UI. If all four hierarchical lists are empty, any user has full administrative access.

For a secure YDB deployment, plan the access model beforehand and define the group lists before starting the cluster for the first time.

Access level lists can contain user or group SIDs. A subject matches a list if it contains their user SID or any of their group SIDs (including nested groups) — a single match is sufficient.

It is recommended to add user groups and separate service accounts to the `*_allowed_sids` access level lists. This way, granting access levels to individual users does not require changing the YDB cluster configuration.

Where the lists are used:

- `database_allowed_sids`, `viewer_allowed_sids`, `monitoring_allowed_sids`, `administration_allowed_sids`
  To access YDB UI and viewer HTTP endpoints.
- `administration_allowed_sids`
  For all administrative checks.
- `bootstrap_allowed_sids`
  Only for cluster bootstrap operation.
- `register_dynamic_node_allowed_sids`
  For registering nodes in a cluster (discovery service and cms subsystem).

Note

Access level lists represent layers of additional privileges:

- An access subject that is not included in any access level list can view only publicly available information about the cluster (for example, a list of databases on the cluster or a list of cluster nodes).
- The `database_allowed_sids` list defines the "database" role: these users are less privileged than viewers and cannot issue any backend call without specifying a database; cluster-wide requests are not allowed.
- The `viewer_allowed_sids`, `monitoring_allowed_sids`, and `administration_allowed_sids` lists form a hierarchy: administration implies monitoring and viewer; monitoring implies viewer. A subject only needs to be in the one list that matches their role — inclusion in a higher list automatically grants all lower privileges.

For example:

- A user of a database (e.g. an application that must stay database-scoped) should be added only to `database_allowed_sids`.
- A viewer should be added only to `viewer_allowed_sids`.
- A monitoring user should be added only to `monitoring_allowed_sids` (they automatically get viewer privileges).
- An administrator should be added only to `administration_allowed_sids` (they automatically get monitoring and viewer privileges).

Built-in Security Configuration

The `disable_builtin_security`, `disable_builtin_groups`, and `disable_builtin_access` flags affect the built-in security configuration that occurs when YDB starts for the first time.

Parameter	Description
`disable_builtin_security`	Disable the built-in security configuration. Built-in security configuration automatically creates a `root` superuser, a set of built-in user groups, and grants access rights to these groups at the root of the cluster. This flag is not saved in the cluster configuration. Default value: `false`.
`disable_builtin_groups`	Do not create built-in user groups even if the default user groups are not specified in the `security_config.default_groups` parameter. Default value: `false`
`disable_builtin_access`	Do not add access rights at the root of the cluster scheme for the built-in user groups even if the default access rights are not specified in the `security_config.default_access` parameter. Default value: `false`

self_management_config

The `self_management_config` section configures distributed configuration V2 and automatic management of cluster components.

Syntax

```
self_management_config:
  enabled: true
  automatic_static_group_management: true
  static_group_self_heal_allowed_nodes:
  - 1
  - 2
  - 3
```

Parameters

Parameter	Default value	Description
`enabled`	`false`	Enables the distributed configuration mechanism in configuration V2.
`automatic_static_group_management`	`false`	Allows distributed configuration to change static group VDisk placement automatically.
`static_group_self_heal_allowed_nodes`	`[]`	Restricts the set of nodes to which SelfHeal can move a static group VDisk. Specify a list of node IDs. An empty list means that no restrictions apply.

system_tablet_backup_config

The system tablet backup mechanism provides incremental copying of cluster metadata — such as Hive, BSController, and SchemeShard — to the local file system of cluster hosts. The backup behavior is configured in the `system_tablet_backup_config` section of the YDB configuration.

Syntax

```
system_tablet_backup_config:
    filesystem:
        path: "/path/to/backup/directory"
    exclude_tablet_ids:
        - 72057594037968897
    max_backups_limit: 3
```

Parameters

Parameter	Default value	Description
`filesystem.path`	—	Absolute path to a directory on the host's local file system for storing backups. The directory must be writable by the YDB process on each host where system tablets run. Only local file systems are supported; network file systems such as NFS are not supported.
`exclude_tablet_ids`	—	List of system tablet identifiers to exclude from backup, for example, to reduce disk load or save space.
`max_backups_limit`	`3`	Maximum number of backups of a single tablet stored on the host. After a new copy is successfully created, the oldest one is automatically deleted when the limit is exceeded.

tls

The `tls` section configures TLS settings for data-in-transit encryption in YDB. Each network protocol can have different TLS settings to secure communication between cluster components and clients.

Interconnect

The YDB actor system interconnect is a specialized protocol for communication between YDB nodes.

Example of enabling TLS for the interconnect:

```
interconnect_config:
   start_tcp: true
   encryption_mode: REQUIRED # or OPTIONAL
   path_to_certificate_file: "/opt/ydb/certs/node.crt"
   path_to_private_key_file: "/opt/ydb/certs/node.key"
   path_to_ca_file: "/opt/ydb/certs/ca.crt"
```

YDB as a server

gRPC

The main YDB API is based on gRPC. It is used for external communication with client applications that work natively with YDB via the SDK or CLI.

Example of enabling TLS for gRPC API:

```
grpc_config:
   cert: "/opt/ydb/certs/node.crt"
   key: "/opt/ydb/certs/node.key"
   ca: "/opt/ydb/certs/ca.crt"
```

Kafka Wire Protocol

YDB exposes a separate network port for the Kafka wire protocol. This protocol is used for external communication with client applications initially designed to work with Apache Kafka.

Example of enabling TLS for the Kafka wire protocol with a file containing both the certificate and the private key:

```
kafka_proxy_config:
    ssl_certificate: "/opt/ydb/certs/node.crt"
```

Example of enabling TLS for the Kafka wire protocol with the certificate and private key in separate files:

```
kafka_proxy_config:
    cert: "/opt/ydb/certs/node.crt"
    key: "/opt/ydb/certs/node.key"
```

HTTP

YDB exposes a separate HTTP network port for running the YDB UI, exposing metrics, and other miscellaneous endpoints.

Example of enabling TLS on the HTTP port, making it HTTPS:

```
monitoring_config:
    monitoring_certificate_file: "/opt/ydb/certs/node.crt"
```

YDB as a client

LDAP

YDB supports LDAP for user authentication. The LDAP protocol has two options for enabling TLS.

Example of enabling TLS for LDAP via the `StartTls` protocol extension:

```
auth_config:
  ldap_authentication:
    use_tls:
      enable: true
      ca_cert_file: "/path/to/ca.pem"
      cert_require: DEMAND
  scheme: "ldap"
```

Example of enabling TLS for LDAP via `ldaps`:

```
auth_config:
  ldap_authentication:
    use_tls:
      enable: false
      ca_cert_file: "/path/to/ca.pem"
      cert_require: DEMAND
  scheme: "ldaps"
```

Federated Queries

Federated queries allow YDB to query various external data sources. Whether these queries occur over TLS-encrypted connections is controlled by the `USE_TLS` setting of `CREATE EXTERNAL DATA SOURCE` queries. No changes to the server-side configuration are required.

Tracing

YDB can send tracing data to an external collector via gRPC.

Example of enabling TLS for tracing data by specifying `grpcs://` protocol:

```
tracing_config:
  backend:
    opentelemetry:
      collector_url: grpcs://example.com:4317
      service_name: ydb
```

Asynchronous Replication

Asynchronous replication synchronizes data between two YDB databases, where one serves as a client to the other. Whether this communication uses TLS-encrypted connections is controlled by the `CONNECTION_STRING` setting of CREATE ASYNC REPLICATION queries. Use the `grpcs://` protocol for TLS connections. No changes to the server-side configuration are required.

When using a custom Certificate Authority (CA), pass its certificate in the `CA_CERT` parameter when creating an instance of asynchronous replication.

table_service_config

The `table_service_config` section contains configuration parameters for the table service, including spilling settings.

resource_manager

The `resource_manager` subsection specifies resource management parameters for the table service.

Vector index level table cache

The vector index level table (`indexImplLevelTable`) `vector_kmeans_tree` stores centroids that YDB accesses at each step of descending the cluster tree during vector search. To avoid re-reading these centroids from the distributed storage on every query, YDB can cache them in memory on each database node.

The cache is created separately on each node, uses LRU eviction, and gradually grows its size up to the specified limit.

```
table_service_config:
  resource_manager:
    kqp_level_cache_max_size_bytes: 0
    kqp_level_cache_increase_batch_size_bytes: 33554432
```

resource_manager.kqp_level_cache_max_size_bytes

Type: `uint64`
Default: `0` (cache disabled)
Description: Maximum size of the vector index level table cache in bytes per database node. Setting a non-zero value enables the cache.

resource_manager.kqp_level_cache_increase_batch_size_bytes

Type: `uint64`
Default: `33554432` (32 MiB)
Description: Step size for increasing the level table cache. The cache grows in chunks of this size up to the value of `kqp_level_cache_max_size_bytes` and decreases by the same chunks when the limit is lowered.

Query execution memory limits

The `resource_manager` subsection sets the spilling threshold relative to the query memory pool on the node. The size of this pool is controlled by the `query_execution_limit_percent` / `query_execution_limit_bytes` parameters in `memory_controller_config` .

```
table_service_config:
  resource_manager:
    spilling_percent: 80
```

resource_manager.spilling_percent

Type: `double`
Default: `80`
Description: The fill threshold of the query memory pool at which YDB starts considering spilling the preferred memory management method. The basis for calculation is the Query Processor pool, whose size is set by `query_execution_limit_percent` / `query_execution_limit_bytes` .

When the total memory consumption by queries on a node exceeds `spilling_percent` percent of the available pool, computational operations that support spilling (Grace Hash Join, aggregations, etc.) receive a signal to offload intermediate data to disk instead of further increasing RAM consumption.

For example, with the default value of `80` , spilling is activated when the query pool is about 80% full.

The threshold applies:

- To the total query memory pool on the node (size — see `query_execution_limit_percent` / `query_execution_limit_bytes`).
- To the resource pool if the query is executed in a workload pool with the `total_memory_limit_percent_per_node` limit.

> **Note**
>
> `spilling_percent` does not set a limit on the size of spilling files on disk. Disk quotas are handled by `local_file_config.max_total_size` in the `spilling_service_config` section.

Interaction with other parameters

Parameter	Level	Role
`query_execution_limit_percent` / `query_execution_limit_bytes`	Node (QP)	Query memory pool size
`spilling_percent`	Query / pool	Pool fill threshold after which spilling is preferred
`activities_limit_percent`	Node	Total memory limit for all activity components (QP, compaction, etc.)

`spilling_percent` determines when the query pool on a node is so full that further growth in RAM should give way to spilling. `activities_limit_percent` limits the memory of activities overall and indirectly affects the available RAM, but does not replace the pool relative to which `spilling_percent` is calculated.

Recommendations

- Decrease `spilling_percent` (for example, to `70`) if you need to offload heavy queries to disk earlier and reduce the risk of exhausting the memory pool.
- Increase `spilling_percent` (for example, to `90`) if disk spilling too often degrades performance and the node has enough RAM.
- Coordinate `spilling_percent` with `query_execution_limit_percent` / `query_execution_limit_bytes`: when increasing the query pool limit, you can raise the spilling threshold if the node has enough RAM.

spilling_service_config

Spilling is a memory management mechanism in YDB that temporarily saves data to disk when RAM is insufficient.

Enabling

Spilling is enabled by default. The following parameter controls enabling and disabling the spilling service.

local_file_config.enable

Location: `table_service_config.spilling_service_config.local_file_config.enable`
Type: `boolean`
Default: `true`
Description: Enables or disables the spilling service. When disabled (`false`), spilling does not function, which may lead to errors when processing large amounts of data.

Possible errors

- `Spilling Service not started` / `Service not started` — attempt to use spilling when the Spilling Service is disabled. See Spilling Service Not Started

```
table_service_config:
  spilling_service_config:
    local_file_config:
      enable: true
```

Main configuration parameters

```
table_service_config:
  spilling_service_config:
    local_file_config:
      root: ""
      max_total_size: 21474836480
```

Directory configuration

local_file_config.root

Type: `string` \n**Default:** `""` (temporary directory) \n**Description:** File directory for storing spilling files.

For each `ydbd` process, a separate directory with a unique name is created. Spilling directories have the following name format:

`node_<node_id>_<spilling_service_id>`

Where:

- `node_id`: node identifier
- `spilling_service_id`: unique instance identifier created once during Spilling Service initialization when the ydbd process starts

Spilling files are stored inside each such directory.

Example of a full path to a spilling directory:

```
/tmp/spilling-tmp-<username>/node_1_32860791-037c-42b4-b201-82a0a337ac80
```

Where:

- `/tmp`: value of the `root` parameter
- `<username>`: username under which the `ydbd` process runs

Important notes:

- When the process starts, all existing spilling directories in the specified directory are automatically deleted. Spilling directories have a special name format that includes an instance identifier generated once when the ydbd process starts. When a new process starts, all directories in the spilling directory that match the name format but have a different `spilling_service_id` from the current one are deleted.
- The directory must have sufficient read and write permissions for the user under which ydbd runs.

> **Note**
>
> Spilling is performed only on database nodes.

Possible errors

- `Permission denied`: insufficient directory access permissions. See Permission Denied

local_file_config.max_total_size

Type: `uint64` \n**Default:** `21474836480` (20 GiB) \n**Description:** Maximum total size of all spilling files on each node. If the limit is exceeded, spilling operations fail with an error. The total spilling limit across the entire cluster equals the sum of `max_total_size` values from all nodes.

Recommendations

- Set the value based on available disk space

Possible errors

- `Total size limit exceeded: X/YMb` : maximum total size of spilling files exceeded. See Total Size Limit Exceeded

Memory management

Relationship with memory_controller_config

Spilling activation is closely related to the memory controller settings. Detailed configuration of `memory_controller_config` is described in a separate article.

The key parameter for spilling is **`activities_limit_percent`**, which determines the amount of memory allocated for query processing activities. This parameter affects the memory available for user queries and, consequently, the frequency of spilling activation.

Spilling threshold in resource_manager

The actual threshold at which computational operations switch to spilling is controlled by the `resource_manager.spilling_percent` parameter. It determines at what fill level of the Query Processor memory pool the intermediate query data starts being offloaded to disk. The pool size is set in `memory_controller_config` . For more details, see the Query execution memory limits section.

Impact on spilling

- When `activities_limit_percent` increases, more memory is available for queries → spilling is activated less often
- When `activities_limit_percent` decreases, less memory is available for queries → spilling is activated more often
- When `spilling_percent` decreases, spilling is triggered at a lower fill level of the query pool
- When `spilling_percent` increases, tasks take longer to increase RAM consumption before switching to spilling

Warning

It is important to note that spilling itself also requires memory. If `activities_limit_percent` is set too high, memory may still run out despite spilling, because the spilling mechanism itself consumes memory resources.

File system requirements

File descriptors

Note

For information on configuring file descriptor limits during initial deployment, see the File descriptor limits section.

Configuration examples

High-load system

For maximum performance in high-load systems, it is recommended to increase the spilling size:

```
table_service_config:
  spilling_service_config:
    local_file_config:
      root: ""
      max_total_size: 107374182400   # 100 GiB
```

Limited resources

For systems with limited resources, it is recommended to use conservative settings:

```
table_service_config:
  spilling_service_config:
    local_file_config:
      root: ""
      max_total_size: 5368709120     # 5 GiB
```

Full example

```
table_service_config:
  spilling_service_config:
    local_file_config:
      enable: true
      root: "/var/spilling"
      max_total_size: 53687091200    # 50 GiB
```

tli_config

The `tli_config` section contains configuration parameters for transaction lock invalidation (TLI) diagnostics.

TLI is a situation where one transaction (the breaker) breaks the optimistic locks of another transaction (the victim), forcing the victim to roll back and retry. For more information about TLI diagnostics, see Transaction lock invalidation.

Configuration parameters

Parameter	Type	Default	Description
`ignored_table_regexes`	repeated string	`[]`	List of table path regular expressions excluded from TLI diagnostics

ignored_table_regexes

Allows excluding specific tables from TLI logging and statistics. If all tables involved in a lock conflict match at least one of the specified regular expressions, no TLI log entry is generated for that conflict.

Changes take effect for new sessions without restarting nodes.

Typical use cases:

- reducing log volume for system or auxiliary tables where conflicts are expected;
- excluding high-conflict queue tables that do not require diagnostics.

Regular expressions are applied to the full table path, e.g. `/Root/mydb/mytable`. The syntax follows ECMAScript regex.

Configuration example

```
tli_config:
  ignored_table_regexes:
    - "/Root/.*/queue_.*"
    - "/Root/system/.*"
```

In this example, the following are excluded from TLI diagnostics:

- tables whose name starts with `queue_` in any database;
- all tables in the `/Root/system/` directory.

hive_config

Hive is a YDB component responsible for launching tablets. In various situations and under different load patterns, you might need to configure its behavior. Hive behavior is configured in the `hive_config` section of the YDB cluster configuration. Some configuration options are also available for editing through the Hive web-viewer interface. Settings configured through the interface take priority over those specified in the configuration. Below are all available options, with the corresponding option name in the interface indicated if the option can be edited through the interface.

Tablet Boot Options

These options allow you to control the speed at which tablets are booted and how nodes are selected for them.

Configuration Parameter Name	Hive Web-viewer Parameter Name	Format	Description	Default Value
`max_tablets_scheduled`	MaxTabletsScheduled	Integer	Maximum number of tablets simultaneously in the startup process on a single node.	100
`max_boot_batch_size`	MaxBootBatchSize	Integer	Maximum number of tablets from the Hive boot queue processed at once.	1000
`node_select_strategy`	NodeSelectStrategy	Enumeration	Node selection strategy for tablet startup. Possible values: • `HIVE_NODE_SELECT_STRATEGY_WEIGHTED_RANDOM` — weighted random selection based on consumption; • `HIVE_NODE_SELECT_STRATEGY_EXACT_MIN` — select node with minimum consumption; • `HIVE_NODE_SELECT_STRATEGY_RANDOM_MIN_7P` — select random node among 7% of nodes with lowest consumption; • `HIVE_NODE_SELECT_STRATEGY_RANDOM` — select random node.	`HIVE_NODE_SELECT_STRATEGY_RANDOM_MI`
`boot_strategy`	—	Enumeration	Controls behavior when starting large numbers of tablets. Possible values: • `HIVE_BOOT_STRATEGY_BALANCED` — when the `max_tablets_scheduled` limit is reached on one node, stops starting new tablets on all nodes. • `HIVE_BOOT_STRATEGY_FAST` — when the `max_tablets_scheduled` limit is reached on one node, continues starting tablets on other nodes. If one node starts tablets slightly slower than others when starting a large number of tablets, then using `HIVE_BOOT_STRATEGY_FAST` will result in fewer tablets being started on that node than on the others. Using `HIVE_BOOT_STRATEGY_BALANCED` in the same situation will distribute tablets evenly across nodes, but their startup will take longer.	`HIVE_BOOT_STRATEGY_BALANCED`
`default_tablet_limit`	—	Nested section	Limits on starting tablets of various types on a single node. Specified as a list format where each element has `type` and `max_count` fields.	Empty section

`default_tablet_preference`	—	Nested section	Priorities for selecting data centers for starting tablets of various types. For each tablet type, you can specify multiple data center groups. Data centers within the same group will have equal priority, with earlier groups having priority over subsequent ones. Example format:
			`default_tablet_preference:`
			`- type: Coordinator`
			`data_centers_preference:`
			`- data_centers_group:`
			`- "dc-1"`
			`- "dc-2"`
			`- data_centers_group:`
			`- "dc-3"`
				Empty section

`system_category_id`	—	Integer	When specifying any number other than 0, all coordinators and mediators are launched in the same data center whenever possible.	1

Example

> **Note**
>
> In the `default_tablet_limit` and `default_tablet_preference` subsections, you need to specify tablet types. Exact tablet type names are specified in the glossary.

```
hive_config:
  max_tablets_scheduled: 10
  node_select_strategy: HIVE_NODE_SELECT_STRATEGY_RANDOM
  boot_strategy: HIVE_BOOT_STRATEGY_FAST
  default_tablet_limit:
    - type: PersQueue
      max_count: 15
    - type: DataShard
      max_count: 100
  default_tablet_preference:
    - type: Coordinator
      data_centers_preference:
        - data_centers_group:
          - "dc-1"
          - "dc-2"
        - data_centers_group:
          - "dc-3"
```

Auto-Balancing Options

These options control the auto-balancing process: in which situations it starts, how many tablets it moves at what intervals, how it selects nodes and tablets. Some options are presented in two variations: for "emergency balancing," i.e., balancing when one or more nodes are overloaded, and for all other types of balancing.

Configuration Parameter Name	Hive Web-viewer Parameter Name	Format	Description	Default V
`min_scatter_to_balance`	MinScatterToBalance	Real number	Threshold for Scatter metric for CPU, Memory, Network resources. Has lower priority than the parameters below.	0.5
`min_cpuscatter_to_balance`	MinCPUScatterToBalance	Real number	Threshold for Scatter metric for CPU resource.	0.5
`min_memory_scatter_to_balance`	MinMemoryScatterToBalance	Real number	Threshold for Scatter metric for Memory resource.	0.5
`min_network_scatter_to_balance`	MinNetworkScatterToBalance	Real number	Threshold for Scatter metric for Network resource.	0.5
`min_counter_scatter_to_balance`	MinCounterScatterToBalance	Real number	Threshold for Scatter metric for virtual Counter resource.	0.02
`min_node_usage_to_balance`	MinNodeUsageToBalance	Real number	Resource consumption on a node below this value is equated to this value. Used to avoid balancing tablets between lightly loaded nodes.	0.1
`max_node_usage_to_kick`	MaxNodeUsageToKick	Real number	Resource consumption threshold on a node for triggering emergency auto-balancing.	0.9
`node_usage_range_to_kick`	NodeUsageRangeToKick	Real number	Minimum difference in resource consumption level between nodes, below which auto-balancing is considered inappropriate.	0.2
`resource_change_reaction_period`	ResourceChangeReactionPeriod	Integer seconds	Frequency of updating aggregated resource consumption statistics.	10
`tablet_kick_cooldown_period`	TabletKickCooldownPeriod	Integer seconds	Minimum time period between movements of a single tablet.	600
`spread_neighbours`	SpreadNeighbours	true/false	Start tablets of the same schema object (table, topic) on different nodes when possible.	true
`node_balance_strategy`	NodeBalanceStrategy	Enumeration	Strategy for selecting the node from which tablets are moved during auto-balancing. Possible values: • `HIVE_NODE_BALANCE_STRATEGY_WEIGHTED_RANDOM` — weighted random selection based on consumption; • `HIVE_NODE_BALANCE_STRATEGY_HEAVIEST` — select node with maximum consumption; • `HIVE_NODE_BALANCE_STRATEGY_RANDOM` — select random node.	`HIVE_NO`
`tablet_balance_strategy`	TabletBalanceStrategy	Enumeration	Strategy for selecting tablet to move during auto-balancing. Possible values: • `HIVE_TABLET_BALANCE_STRATEGY_WEIGHTED_RANDOM` — weighted random selection based on consumption; • `HIVE_TABLET_BALANCE_STRATEGY_HEAVIEST` — select tablet with maximum consumption; • `HIVE_TABLET_BALANCE_STRATEGY_RANDOM` — select random tablet.	`HIVE_TA`
`min_period_between_balance`	MinPeriodBetweenBalance	Real number seconds	Minimum time period between two auto-balancing iterations. Does not apply to emergency balancing.	0.2
`balancer_inflight`	BalancerInflight	Integer	Number of tablets simultaneously restarting during auto-balancing process. Does not apply to emergency balancing.	1

`max_movements_on_auto_balancer`	MaxMovementsOnAutoBalancer	Integer	Number of tablet movements per auto-balancing iteration. Does not apply to emergency balancing.	1
`continue_auto_balancer`	ContinueAutoBalancer	true/false	When enabled, the next balancing iteration starts without waiting for the end of `resource_change_reaction_period`.	true
`min_period_between_emergency_balance`	MinPeriodBetweenEmergencyBalance	Real number seconds	Similar to `min_period_between_balance`, but for emergency balancing.	0.1
`emergency_balancer_inflight`	EmergencyBalancerInfligh	Integer	Similar to `balancer_inflight`, but for emergency balancing.	1
`max_movements_on_emergency_balancer`	MaxMovementsOnEmergencyBalancer	Integer	Similar to `max_movements_on_auto_balancer`, but for emergency balancing.	2
`continue_emergency_balancer`	ContinueEmergencyBalancer	true/false	Similar to `continue_auto_balancer`, but for emergency balancing.	true
`check_move_expediency`	CheckMoveExpediency	true/false	Check the expediency of tablet movements. If auto-balancing leads to increased Hive CPU resource consumption, you can disable this option.	true
`object_imbalance_to_balance`	ObjectImbalanceToBalance	Real number	Threshold for single object tablet imbalance metric.	0.02
`less_system_tablets_moves`	LessSystemTabletMoves	true/false	Minimize movement of system tablets during auto-balancing.	true
`balancer_ignore_tablet_types`	BalancerIgnoreTabletTypes	List of tablet types. When set through Hive UI — separated by semicolon.	Tablet types that are not subject to auto-balancing.	Empty lis

Examples

With this configuration file, you can completely disable all types of tablet auto-balancing between nodes.

```
hive_config:
  min_cpuscatter_to_balance: 1.0
  min_memory_scatter_to_balance: 1.0
  min_network_scatter_to_balance: 1.0
  min_counter_scatter_to_balance: 1.0
  max_node_usage_to_kick: 3.0
  object_imbalance_to_balance: 1.0
```

With this configuration file, you can disable all types of auto-balancing between nodes for tablets participating in transaction distribution, i.e., coordinators and mediators. Exact tablet type names are specified in the glossary.

```
hive_config:
  balancer_ignore_tablet_types:
    - Coordinator
    - Mediator
```

When using Hive UI for the same effect, you need to enter `Coordinator;Mediator` in the input field for the BalancerIgnoreTabletTypes setting.

Computational Resource Consumption Metrics Collection Options

Hive collects computational resource consumption metrics from each node — CPU time, memory, network — both overall per node and broken down by tablets. These settings allow you to control the collection of these metrics, their normalization and aggregation.

Configuration Parameter Name	Hive Web-viewer Parameter Name	Format	Description	Default Value
`max_resource_cpu`	MaxResourceCPU	Integer microseconds	Maximum CPU consumption per node per second. Default value, used only if the node does not provide a value when registering with Hive.	10000000

`max_resource_memory`	MaxResourceMemory	Integer bytes	Maximum memory consumption per node. Default value, used only if the node does not provide a value when registering with Hive.	512000000000
`max_resource_network`	MaxResourceNetwork	Integer bytes/second	Maximum bandwidth consumption per node. Default value, used only if the node does not provide a value when registering with Hive.	1000000000
`max_resource_counter`	MaxResourceCounter	Integer	Maximum consumption of virtual Counter resource per node.	100000000
`metrics_window_size`	MetricsWindowSize	Integer milliseconds	Size of the window over which tablet resource consumption metrics are aggregated.	60000
`resource_overcommitment`	ResourceOvercommitment	Real number	Overcommitment factor for node resources.	3.0
`pools_to_monitor_for_usage`	—	Pool names separated by comma	Actor system pools whose consumption is taken into account when calculating node resource consumption.	System,User,IC

Storage Channel Distribution Options

Listed here are options related to distributing tablet channels across storage groups: taking into account various metrics, selecting groups, and the channel auto-balancing process across groups.

> **Note**
>
> This table contains advanced settings that in most cases do not require modification.

Configuration Parameter Name	Hive Web-viewer Parameter Name	Format	Description	Default Value
`default_unit_iops`	DefaultUnitIOPS	Integer	Default value for IOPS of one channel.	1
`default_unit_throughput`	DefaultUnitThroughput	Integer bytes/second	Default value for throughput consumption by one channel.	1000
`default_unit_size`	DefaultUnitSize	Integer bytes	Default value for disk space consumption by one channel.	100000000
`storage_overcommit`	StorageOvercommit	Real number	Overcommitment factor for storage group resources.	1.0
`storage_balance_strategy`	StorageBalanceStrategy	Enumeration	Selection of parameter used for distributing tablet channels across storage groups. Possible values: • `HIVE_STORAGE_BALANCE_STRATEGY_IOPS` — only IOPS is considered; • `HIVE_STORAGE_BALANCE_STRATEGY_THROUGHPUT` — only throughput consumption is considered; • `HIVE_STORAGE_BALANCE_STRATEGY_SIZE` — only occupied space volume is considered; • `HIVE_STORAGE_BALANCE_STRATEGY_AUTO` — the parameter with maximum consumption among the above is considered;	`HIVE_STORAGE_BALANC`
`storage_safe_mode`	StorageSafeMode	true/false	Check for exceeding maximum resource consumption of storage groups.	true

`storage_select_strategy`	StorageSelectStrategy	Enumeration	Strategy for selecting storage group for tablet channel. Possible values: • `HIVE_STORAGE_SELECT_STRATEGY_WEIGHTED_RANDOM` — weighted random selection based on consumption; • `HIVE_STORAGE_SELECT_STRATEGY_EXACT_MIN` — select group with minimum consumption; • `HIVE_STORAGE_SELECT_STRATEGY_RANDOM_MIN_7P` — select random group among 7% of groups with lowest consumption; • `HIVE_STORAGE_SELECT_STRATEGY_RANDOM` — select random group; • `HIVE_STORAGE_SELECT_STRATEGY_ROUND_ROBIN` — select group within storage pool using Round-robin principle.	`HIVE_STORAGE_SELECT`
`min_period_between_reassign`	MinPeriodBetweenReassign	Integer seconds	Minimum time period between storage group reassignments for channels of one tablet.	300
`storage_pool_fresh_period`	StoragePoolFreshPeriod	Integer milliseconds	Frequency of updating storage pool information.	60000
`space_usage_penalty_threshold`	SpaceUsagePenaltyThreshold	Real number	Minimum ratio of free space in target group to free space in source group, at which the target group will be penalized by applying a multiplicative penalty to the weight when moving a channel.	1.1
`space_usage_penalty`	SpaceUsagePenalty	Real number	Penalty factor for the penalization described above.	0.2
`channel_balance_strategy`	ChannelBalanceStrategy	Enumeration	Strategy for selecting channel for reassignment during channel balancing. Possible values: • `HIVE_CHANNEL_BALANCE_STRATEGY_WEIGHTED_RANDOM` — weighted random selection based on consumption; • `HIVE_CHANNEL_BALANCE_STRATEGY_HEAVIEST` — select channel with maximum consumption; • `HIVE_CHANNEL_BALANCE_STRATEGY_RANDOM` — select random channel.	`HIVE_CHANNEL_BALANC`
`max_channel_history_size`	MaxChannelHistorySize	Integer	Maximum size of channel history.	200
`storage_info_refresh_frequency`	StorageInfoRefreshFrequency	Integer milliseconds	Frequency of updating storage pool information.	600000
`min_storage_scatter_to_balance`	MinStorageScatterToBalance	Real number	Threshold for Scatter metric for storage groups.	999
`min_group_usage_to_balance`	MinGroupUsageToBalance	Real number	Storage group resource consumption threshold below which balancing is not started.	0.1
`storage_balancer_inflight`	StorageBalancerInflight	Integer	Number of tablets simultaneously restarting during channel balancing.	1

Restart Tracking Options

Hive tracks how often various nodes and tablets restart to identify problematic ones. Using these options, you can configure which tablets or nodes will be considered problematic and how this will affect them. Based on this statistics, nodes and tablets are included in the HealthCheck API report.

Tablet Restart Tracking Options

Configuration Parameter Name	Hive Web-viewer Parameter Name	Format	Description	Default Value
`tablet_restart_watch_period`	—	Integer seconds	Size of window over which statistics on tablet restart count are collected. **This period is used only for statistics passed to HealthCheck.**	3600
`tablet_restarts_period`	—	Integer milliseconds	Size of window over which tablet restart count is calculated for penalizing problematic tablet startup.	1000
`tablet_restarts_max_count`	—	Integer	Number of restarts in the `tablet_restarts_period` window, exceeding which triggers penalization.	2
`postopone_start_period`	—	Integer milliseconds	Frequency of startup attempts for problematic tablets.	1000

Node Restart Tracking Options

Configuration Parameter Name	Hive Web-viewer Parameter Name	Format	Description	Default Value
`node_restart_watch_period`	—	Integer seconds	Size of window over which statistics on node restart count are collected.	3600

`node_restarts_for_penalty`	NodeRestartsForPenalty	Integer	Number of restarts in the `node_restart_watch_period` window after which nodes receive priority reduction.	3

Miscellaneous

Listed here are additional Hive settings.

> **Note**
>
> This table contains advanced settings that in most cases do not require modification.

Configuration Parameter Name	Hive Web-viewer Parameter Name	Format	Description	Default Value
`drain_inflight`	DrainInflight	Integer	Number of tablets simultaneously restarting during graceful movement of all tablets from one node (drain).	10
`request_sequence_size`	—	Integer	Number of tablet identifiers that database Hive requests from root Hive at once.	1000
`min_request_sequence_size`	—	Integer	Minimum number of tablet identifiers that root Hive allocates for database Hive at once.	1000
`max_request_sequence_size`	—	Integer	Maximum number of tablet identifiers allocated for database Hive at once.	1000000
`node_delete_period`	—	Integer seconds	Inactivity period after which a node is deleted from the Hive database.	3600
`warm_up_enabled`	WarmUpEnabled	true/false	When this option is enabled, database Hive waits for all nodes to connect before starting tablets during startup. When disabled, all tablets can be started on the first connected node.	true
`warm_up_boot_waiting_period`	MaxWarmUpBootWaitingPeriod	Integer milliseconds	Waiting time for all known nodes to start during database startup.	30000
`max_warm_up_period`	MaxWarmUpPeriod	Integer seconds	Maximum waiting time for node startup during database startup.	600
`enable_destroy_operations`	—	true/false	Whether destructive manual operations are allowed.	false

`max_pings_in_flight`	—	Integer	Maximum number of connections being established with nodes in parallel.	1000
`cut_history_deny_list`	—	List of tablet types separated by comma	List of tablet types for which history cleanup operation is ignored.	ColumnShard,KeyValue,PersQueue,BlobDepo
`cut_history_allow_list`	—	List of tablet types separated by comma	List of tablet types for which history cleanup operation is allowed.	DataShard
`scale_recommendation_refresh_frequency`	ScaleRecommendationRefreshFrequency	Integer milliseconds	How often the recommendation for the number of compute nodes is updated.	60000
`scale_out_window_size`	ScaleOutWindowSize	Integer	Number of buckets based on which the decision to recommend increasing the number of compute nodes is made.	15
`scale_in_window_size`	ScaleInWindowSize	Integer	Number of buckets based on which the decision to recommend decreasing the number of compute nodes is made.	5
`target_tracking_cpumargin`	TargetTrackingCPUMargin	Real number	Allowable deviation from target CPU utilization value during autoscaling.	0.1
`dry_run_target_tracking_cpu`	DryRunTargetTrackingCPU	Real number	Target CPU utilization value for testing how autoscaling would work.	0

kafka_proxy_config

The `kafka_proxy_config` section of the YDB configuration file enables and configures Kafka Proxy, which provides access to work with YDB Topics via Kafka API.

Description of parameters

Parameter	Type	Default value	Description
`enable_kafka_proxy`	bool	`false`	Enables or disables Kafka Proxy.
`listening_port`	int32	`9092`	The port on which the Kafka API will be available.
`transaction_timeout_ms`	uint32	`300000` (5 minutes)	The maximum timeout for Kafka transactions, after which the transaction will be cancelled.
`auto_create_topics_enable`	bool	`false`	Enables automatic creation of topics when they are accessed. Analogous to the same option in Apache Kafka.
`auto_create_consumers_enable`	bool	`true`	Enables automatic registration of consumers when they are accessed.
`topic_creation_default_partitions`	uint32	`1`	The number of partitions that will be created if the number of partitions is not specified when adding a topic via the Kafka protocol. Analogous to num.partitions option in Apache Kafka.
`ssl_cerificate`	string	—	The path to the SSL certificate file, which includes both the certificate file and the key file. When this parameter is specified, Kafka Proxy automatically starts processing requests using the specified SSL certificate.
`cert`	string	—	The path to the SSL certificate file. When this parameter is specified, Kafka Proxy automatically starts processing requests using the specified SSL certificate.
`key`	string	—	The path to the SSL key file.

Example of a completed config

```yaml
kafka_proxy_config:
  enable_kafka_proxy: true
  listening_port: 9092
  transaction_timeout_ms: 300000 # 5 minutes
  auto_create_topics_enable: true
  auto_create_consumers_enable: true
  topic_creation_default_partitions: 1
  cert: /path/to/cert.pem
  key: /path/to/key.pem
```

Reference on YDB observability

This section of YDB documentation covers various observability-related topics that do **not** depend on a chosen deployment method.

- Metrics reference
- Grafana dashboards for YDB
- Tracing in YDB
- Passing external trace-id to YDB

Metrics reference

This document provides a reference for the main YDB system metrics used for monitoring cluster state, diagnosing performance, and analyzing load.

How to view current metric values in the built-in web interface and configure their collection in Prometheus and Grafana is described in the Setting up YDB cluster monitoring section.

Resource usage metrics

Metric name Type, units	Description Labels
`resources.storage.used_bytes` `IGAUGE`, bytes	Size of user and service data stored in the distributed network storage. `resources.storage.used_bytes` = `resources.storage.table.used_bytes` + `resources.storage.topic.used_bytes`.
`resources.storage.table.used_bytes` `IGAUGE`, bytes	Size of user and service data stored by tables in the distributed network storage. Service data includes data of primary, secondary indexes, vector indexes, full-text indexes, local Bloom indexes, and local min_max index.
`resources.storage.topic.used_bytes` `IGAUGE`, bytes	Size of the distributed network storage used by topics. Equals the sum of `topic.storage_bytes` values of all topics.
`resources.storage.limit_bytes` `IGAUGE`, bytes	Limit on the size of user and system data that the database can store in the distributed network storage.

Common gRPC API metrics

Metric name Type, units	Description Labels
`api.grpc.request.bytes` `RATE`, bytes	Size of requests received by the database in a certain time period. Labels: - *api_service* – name of the gRPC API service, for example `table` or `data_streams`. - *method* – name of the gRPC API service method, for example `ExecuteDataQuery` (for the `table` service), or `PutRecord`, `GetRecords` (for the `data_streams` service).
`api.grpc.request.dropped_count` `RATE`, count	Number of requests whose processing was terminated at the transport (gRPC) level due to an error. Labels: - *api_service* – name of the gRPC API service, for example `table`. - *method* – name of the gRPC API service method, for example `ExecuteDataQuery`.
`api.grpc.request.inflight_count` `IGAUGE`, count	Number of requests being processed simultaneously by the database in a certain time period. Labels: - *api_service* – name of the gRPC API service, for example `table`. - *method* – name of the gRPC API service method, for example `ExecuteDataQuery`.
`api.grpc.request.inflight_bytes` `IGAUGE`, bytes	Size of requests being processed simultaneously by the database in a certain time period. Labels: - *api_service* – name of the gRPC API service, for example `table`. - *method* – name of the gRPC API service method, for example `ExecuteDataQuery`.
`api.grpc.response.bytes` `RATE`, bytes	Size of responses sent by the database in a certain time period. Labels: - *api_service* – name of the gRPC API service, for example `table`. - *method* – name of the gRPC API service method, for example `ExecuteDataQuery`.
`api.grpc.response.count` `RATE`, count	Number of responses sent by the database in a certain time period. Labels: - *api_service* – name of the gRPC API service, for example `table`. - *method* – name of the gRPC API service method, for example `ExecuteDataQuery`. - *status* – request execution status; for more details on statuses, see the Error handling section.
`api.grpc.response.dropped_count` `RATE`, count	Number of responses whose sending was terminated at the transport (gRPC) level due to an error. Labels: - *api_service* – name of the gRPC API service, for example `table`. - *method* – name of the gRPC API service method, for example `ExecuteDataQuery`.
`api.grpc.response.issues` `RATE`, count	Number of errors of a certain type that occurred during query execution in a certain time period. Labels: - *issue_type* – error type, the only value is `optimistic_locks_invalidation`; for more details on lock invalidation, see the Transactions and queries to YDB section.

gRPC API metrics for topics

Metric name Type, units	Description Labels
`grpc.topic.stream_read.commits` `RATE`, units	Number of commits of the `Ydb::TopicService::StreamRead` method. Labels: - *topic* – topic name. - *consumer* – consumer name.

`grpc.topic.stream_read.bytes` `RATE`, units	Number of bytes read by the `Ydb::TopicService::StreamRead` method. Labels: - *topic* – topic name. - *consumer* – consumer name.
`grpc.topic.stream_read.messages` `RATE`, units	Number of messages read by the `Ydb::TopicService::StreamRead` method. Labels: - *topic* – topic name. - *consumer* – consumer name.
`grpc.topic.stream_read.partition_session.errors` `RATE`, units	Number of errors when working with a partition. Labels: - *topic* – topic name. - *consumer* – reader name.
`grpc.topic.stream_read.partition_session.started` `RATE`, count	Number of sessions started per unit of time. Labels: - *topic* – topic name. - *consumer* – reader name.
`grpc.topic.stream_read.partition_session.stopped` `RATE`, count	Number of sessions stopped per unit of time. Labels: - *topic* – topic name. - *consumer* – reader name.
`grpc.topic.stream_read.partition_session.starting_count` `RATE`, count	Number of sessions being started (that is, the client received a command to start a session, but the client has not started the session yet). Labels: - *topic* – topic name. - *consumer* – reader name.
`grpc.topic.stream_read.partition_session.stopping_count` `RATE`, count	Number of sessions being stopped. Labels: - *topic* – topic name. - *consumer* – reader name.
`grpc.topic.stream_read.partition_session.count` `RATE`, count	Number of partition_session. Labels: - *topic* – topic name. - *consumer* – reader name.
`grpc.topic.stream_write.bytes` `RATE`, bytes	Number of bytes written by the `Ydb::TopicService::StreamWrite` method. Labels: - *topic* – topic name.
`grpc.topic.stream_write.uncommitted_bytes` `RATE`, bytes	Number of bytes written by the `Ydb::TopicService::StreamWrite` method within uncommitted transactions. Labels: - *topic* – topic name.
`grpc.topic.stream_write.errors` `RATE`, count	Number of errors when calling the `Ydb::TopicService::StreamWrite` method. Labels: - *topic* – topic name.
`grpc.topic.stream_write.messages` `RATE`, count	Number of messages written by the `Ydb::TopicService::StreamWrite` method. Labels: - *topic* – topic name.
`grpc.topic.stream_write.uncommitted_messages` `RATE`, count	Number of messages written by the `Ydb::TopicService::StreamWrite` method within uncommitted transactions. Labels: - *topic* – topic name.
`grpc.topic.stream_write.partition_throttled_milliseconds` `HIST_RATE`, count	Histogram counter. Intervals are set in milliseconds. Shows the number of messages that waited on the quota. Labels: - *topic* – topic name.
`grpc.topic.stream_write.sessions_active_count` `GAUGE`, count	Number of open write sessions. Labels: - *topic* – topic name.
`grpc.topic.stream_write.sessions_created` `RATE`, count	Number of created write sessions. Labels: - *topic* – topic name.

HTTP API metrics

Metric name Type, units	Description Labels

`api.http.data_streams.request.count` `RATE`, pieces	Number of requests over HTTP. Labels: - *method* – HTTP API service method name, e.g., `PutRecord`, `GetRecords`. - *topic* – topic name.
`api.http.data_streams.request.bytes` `RATE`, bytes	Total size of requests over HTTP. Labels: - *method* – HTTP API service method name, in this case only `PutRecord`. - *topic* – topic name.
`api.http.data_streams.response.count` `RATE`, pieces	Number of responses over HTTP. Labels: - *method* – HTTP API service method name, e.g., `PutRecord`, `GetRecords`. - *topic* – topic name. - *code* – HTTP response code.
`api.http.data_streams.response.bytes` `RATE`, bytes	Total size of responses over HTTP. Labels: - *method* – HTTP API service method name, in this case only `GetRecords`. - *topic* – topic name.
`api.http.data_streams.response.duration_milliseconds` `HIST_RATE`, pieces	Histogram counter. Intervals are specified in milliseconds. Shows the number of responses whose execution time falls within a certain interval. Labels: - *method* – HTTP API service method name. - *topic* – topic name.
`api.http.data_streams.get_records.messages` `RATE`, pieces	Number of messages read by the `GetRecords` method. Labels: - *topic* – topic name.
`api.http.data_streams.put_record.messages` `RATE`, pieces	Number of messages sent by the `PutRecord` method. Labels: - *topic* – topic name.
`api.http.data_streams.put_records.failed_messages` `RATE`, pieces	Number of messages sent by the `PutRecords` method that were not written. Labels: - *topic* – topic name.
`api.http.data_streams.put_records.successful_messages` `RATE`, pieces	Number of messages sent by the `PutRecords` method that were successfully written. Labels: - *topic* – topic name.
`api.http.data_streams.put_records.total_messages` `RATE`, pieces	Number of messages sent by the `PutRecords` method. Labels: - *topic* – topic name.

Kafka API metrics

Metric name Type, units	Description Labels
`api.kafka.request.count` `RATE`, pieces	Number of requests over the Kafka protocol per unit time. Labels: - *method* – Kafka API service method name, e.g., `PRODUCE`, `SASL_HANDSHAKE`.
`api.kafka.request.bytes` `RATE`, bytes	Total size of requests over the Kafka protocol per unit time. Labels: - *method* – Kafka API service method name, e.g., `PRODUCE`, `SASL_HANDSHAKE`.
`api.kafka.response.count` `RATE`, count	Number of responses via the Kafka protocol per unit time. Labels: - *method* – name of the Kafka API service method, e.g., `PRODUCE`, `SASL_HANDSHAKE`. - *error_code* – Kafka response code.
`api.kafka.response.bytes` `RATE`, bytes	Total size of responses via the Kafka protocol per unit time. Labels: - *method* – name of the Kafka API service method, e.g., `PRODUCE`, `SASL_HANDSHAKE`.
`api.kafka.response.duration_milliseconds` `HIST_RATE`, units	Histogram counter. Defines a set of intervals in milliseconds and for each of them shows the number of requests with execution time falling within that interval. Labels: - *method* – Kafka API service method name.
`api.kafka.produce.failed_messages` `RATE`, units	Number of messages per unit time sent by the `PRODUCE` method that were not written. Labels: - *topic* – topic name.
`api.kafka.produce.successful_messages` `RATE`, units	Number of messages per unit time sent by the `PRODUCE` method that were successfully written. Labels: - *topic* – topic name.

`api.kafka.produce.total_messages` `RATE`, units	Number of messages per unit time sent by the `PRODUCE` method. Labels: - *topic* – topic name.

Session metrics

Metric name Type, units	Description Labels
`table.session.active_count` `IGAUGE`, units	Number of sessions currently open by clients.
`table.session.closed_by_idle_count` `RATE`, units	Number of sessions closed by the database server in a certain period of time due to exceeding the time allocated for an inactive session's lifetime.

Transaction processing metrics

Transaction execution duration can be analyzed using a histogram counter. Intervals are set in milliseconds. The chart shows the number of transactions whose duration falls within a certain time interval.

Metric name Type, units	Description Labels
`table.transaction.total_duration_milliseconds` `HIST_RATE`, count	Number of transactions with a specific execution duration on the server and client. Execution duration is the time from the moment of explicit or implicit transaction opening to the moment of committing changes or rolling back. Includes transaction processing time on the server and time on the client between sending different queries within the same transaction. Labels: - *tx_kind* – transaction type, possible values `read_only`, `read_write`, `write_only`, `pure`.
`table.transaction.server_duration_milliseconds` `HIST_RATE`, count	Number of transactions with a specific execution duration on the server. Execution duration is the time of query execution within a transaction on the server. Does not include wait time on the client between sending individual queries within the same transaction. Labels: - *tx_kind* – transaction type, possible values `read_only`, `read_write`, `write_only`, `pure`.
`table.transaction.client_duration_milliseconds` `HIST_RATE`, count	Number of transactions with a specific execution duration on the client. Execution duration is the wait time on the client between sending individual queries within the same transaction. Does not include query execution time on the server. Labels: - *tx_kind* – transaction type, possible values `read_only`, `read_write`, `write_only`, `pure`.

Query processing metrics

Metric name Type, units	Description Labels
`table.query.request.bytes` `RATE`, bytes	Size of YQL query text and parameter values for queries that arrived at the database in a certain period of time.
`table.query.request.parameters_bytes` `RATE`, bytes	Size of parameters for queries that arrived at the database in a certain period of time.
`table.query.response.bytes` `RATE`, bytes	Size of responses sent by the database in a certain period of time.
`table.query.compilation.latency_milliseconds` `HIST_RATE`, units	Histogram counter. Intervals are set in milliseconds. Shows the number of successfully completed compilation requests whose duration falls within a certain time interval.
`table.query.compilation.active_count` `IGAUGE`, units	Number of compilations currently in progress.
`table.query.compilation.count` `RATE`, units	Number of compilations that completed successfully in a certain period of time.
`table.query.compilation.errors` `RATE`, units	Number of compilations that failed in a certain period of time.
`table.query.compilation.cache_hits` `RATE`, units	Number of queries in a certain period of time that did not require compiling the query because a previously created plan was in the prepared query cache.
`table.query.compilation.cache_misses` `RATE`, count	The number of queries in a given period of time that required compiling a query.
`table.query.execution.latency_milliseconds` `HIST_RATE`, count	Histogram counter. Intervals are specified in milliseconds. Shows the number of queries whose execution time falls within a certain interval.

Row table partition metrics

Metric name Type, units of measurement	Description Labels

`table.datashard.row_count` `GAUGE`, count	Number of rows in all row tables of the database.
`table.datashard.size_bytes` `GAUGE`, bytes	Size of data in all row tables of the database.
`table.datashard.used_core_percents` `HIST_GAUGE`, %	Histogram counter. Intervals are specified in percentages. Shows the number of partitions of row tables that use computing resources in a proportion that falls within a certain interval.
`table.datashard.read.rows` `RATE`, count	Number of rows read by all partitions of all row tables in the database during a given period of time.
`table.datashard.read.bytes` `RATE`, bytes	Size of data read by all partitions of all row tables in the database during a given period of time.
`table.datashard.write.rows` `RATE`, count	Number of rows written by all partitions of all row tables in the database during a given period of time.
`table.datashard.write.bytes` `RATE`, bytes	Size of data written by all partitions of all row tables in the database during a given period of time.
`table.datashard.scan.rows` `RATE`, count	Number of rows read via gRPC API calls `StreamExecuteScanQuery` or `StreamReadTable` by all partitions of all row tables in the database over a certain time period.
`table.datashard.scan.bytes` `RATE`, bytes	Size of data read via gRPC API call `StreamExecuteScanQuery` or `StreamReadTable` by all partitions of all row tables in the database over a certain time period.
`table.datashard.bulk_upsert.rows` `RATE`, count	Number of rows added via gRPC API call `BulkUpsert` to all partitions of all row tables in the database over a certain time period.
`table.datashard.bulk_upsert.bytes` `RATE`, bytes	Size of data added via gRPC API call `BulkUpsert` to all partitions of all row tables in the database over a certain time period.
`table.datashard.erase.rows` `RATE`, count	Number of rows deleted from all row tables in the database during a given period of time.
`table.datashard.erase.bytes` `RATE`, bytes	Size of data deleted from all row tables in the database during a given period of time.
`table.datashard.cache_hit.bytes` `RATE`, bytes	Total volume of row table data successfully retrieved from memory (cache). A larger volume of data retrieved from the cache indicates efficient cache usage without accessing the distributed storage.
`table.datashard.cache_miss.bytes` `RATE`, bytes	Total volume of row table data that was requested but not found in memory (cache) and was read from distributed storage. Indicates potential areas for cache optimization.

Column table partition metrics

Metric name Type, units of measurement	Description Labels
`table.columnshard.write.rows` `RATE`, count	Number of rows written by all partitions of all columnar tables in the database during a given period of time.
`table.columnshard.write.bytes` `RATE`, bytes	Size of data written by all partitions of all columnar tables in the database during a given period of time.
`table.columnshard.scan.rows` `RATE`, count	Number of rows read via gRPC API calls `StreamExecuteScanQuery` or `StreamReadTable` by all partitions of all columnar tables in the database over a certain time period.
`table.columnshard.scan.bytes` `RATE`, bytes	Size of data read via gRPC API call `StreamExecuteScanQuery` or `StreamReadTable` by all partitions of all columnar tables in the database over a certain time period.
`table.columnshard.bulk_upsert.rows` `RATE`, count	Number of rows added via gRPC API call `BulkUpsert` to all partitions of all columnar tables in the database over a certain time period.
`table.columnshard.bulk_upsert.bytes` `RATE`, bytes	Size of data added via gRPC API call `BulkUpsert` to all partitions of all columnar tables in the database over a certain time period.

Resource usage metrics (Dedicated mode only)

Metric name Type units of measurement	Description Labels
`resources.cpu.used_core_percents` `RATE`, %	CPU usage. A value of `100` means that one of the cores is 100% utilized. The value can be greater than `100` for configurations with more than 1 core. Labels: - *pool* – compute pool, possible values `user`, `system`, `batch`, `io`, `ic`.
`resources.cpu.limit_core_percents` `IGAUGE`, %	CPU available to the database as a percentage. For example, for a database of three nodes with 4 cores in `pool=user` on each node, the value of this sensor will be `1200`. Labels: - *pool* – compute pool, possible values `user`, `system`, `batch`, `io`, `ic`.
`resources.memory.used_bytes` `IGAUGE`, bytes	RAM used by database nodes.

`resources.memory.limit_bytes` `IGAUGE`, bytes	RAM available to database nodes.

Query processing metrics (Dedicated mode only)

Metric name Type units of measurement	Description Labels
`table.query.compilation.cache_evictions` `RATE`, count	Number of queries evicted from the prepared query cache during a given period of time.
`table.query.compilation.cache_size_bytes` `IGAUGE`, bytes	Size of the prepared query cache.
`table.query.compilation.cached_query_count` `IGAUGE`, count	Number of queries in the prepared query cache.

Topic metrics

Metric name Type, units of measurement	Description Labels
`topic.producers_count` `GAUGE`, count	Number of unique sources of the topic. Labels: - *topic* – topic name.
`topic.storage_bytes` `GAUGE`, bytes	Topic size in bytes. Labels: - *topic* – topic name.
`topic.read.bytes` `RATE`, bytes	Number of bytes read from the topic. Labels: - *topic* – topic name. - *consumer* – reader name.
`topic.read.messages` `RATE`, count	Number of messages read from the topic. Labels: - *topic* – topic name. - *consumer* – reader name.
`topic.read.lag_messages` `GAUGE`, count	Total number of messages not yet read by the given reader across the topic. The metric serves as an indicator of reader lag. An increase in the value means the reader is falling behind the message flow — for example, due to a reader stop, partition rebalancing, or a write load spike. Labels: - *topic* – topic name. - *consumer* – reader name.
`topic.read.lag_milliseconds` `HIST_RATE`, count	Histogram counter. Intervals are specified in milliseconds. Shows the number of messages for which the difference between the read time and the message creation time falls within a given interval. Labels: - *topic* – topic name. - *consumer* – reader name.
`topic.write.bytes` `RATE`, bytes	Size of written data. Labels: - *topic* – topic name.
`topic.write.uncommited_bytes` `RATE`, bytes	Size of data written as part of not yet completed transactions. Labels: - *topic* – topic name.
`topic.write.uncompressed_bytes` `RATE`, bytes	Size of decompressed written data. Labels: - *topic* – topic name.
`topic.write.messages` `RATE`, count	Number of written messages. Labels: - *topic* – topic name.
`topic.write.uncommitted_messages` `RATE`, count	Number of messages written as part of not yet completed transactions. Labels: - *topic* – topic name.
`topic.write.message_size_bytes` `HIST_RATE`, count	Histogram counter. Intervals are specified in bytes. Shows the number of messages whose size matches the interval boundaries. Labels: - *topic* – topic name.
`topic.write.lag_milliseconds` `HIST_RATE`, count	Histogram counter. Intervals are specified in milliseconds. Shows the number of messages for which the difference between the write time and the message creation time falls within a given interval. Labels: - *topic* – topic name.

Aggregated topic partition metrics

The following table lists aggregated partition metrics for a topic. Maximum and minimum values are calculated across all partitions of the specified topic.

Metric name Type, unit of measurement	Description Labels
`topic.partition.init_duration_milliseconds_max` `GAUGE`, milliseconds	Maximum partition initialization delay. Labels: - *topic* – topic name.
`topic.partition.producers_count_max` `GAUGE`, count	Maximum number of sources in a partition. Labels: - *topic* – topic name.
`topic.partition.storage_bytes_max` `GAUGE`, bytes	Maximum partition size in bytes. Labels: - *topic* – topic name.
`topic.partition.uptime_milliseconds_min` `GAUGE`, count	Minimum partition uptime after restart. Normally, during a rolling restart, `topic.partition.uptime_milliseconds_min` is close to 0; after the rolling restart finishes, the value of `topic.partition.uptime_milliseconds_min` should increase to infinity. Labels: - *topic* – topic name.
`topic.partition.total_count` `GAUGE`, count	Total number of partitions in the topic. Labels: - *topic* – topic name.
`topic.partition.alive_count` `GAUGE`, count	Number of partitions reporting their metrics. Labels: - *topic* – topic name.
`topic.partition.committed_end_to_end_lag_milliseconds_max` `GAUGE`, milliseconds	Maximum (across all partitions) difference between the current time and the creation time of the last committed message. Labels: - *topic* – topic name. - *consumer* – consumer name.
`topic.partition.committed_lag_messages_max` `GAUGE`, units	Maximum (across all partitions) difference between the last partition offset and the committed partition offset. Labels: - *topic* – topic name. - *consumer* – consumer name.
`topic.partition.committed_read_lag_milliseconds_max` `GAUGE`, milliseconds	Maximum (across all partitions) difference between the current time and the write time of the last committed message. Labels: - *topic* – topic name. - *consumer* – consumer name.
`topic.partition.end_to_end_lag_milliseconds_max` `GAUGE`, milliseconds	Difference between the current time and the minimum creation time among all messages read in the last minute across all partitions. Labels: - *topic* – topic name. - *consumer* – consumer name.
`topic.partition.lag_messages_max` `GAUGE`, units	Maximum difference (across all partitions) between the last offset in the partition and the last read offset. Labels: - *topic* – topic name. - *consumer* – consumer name.
`topic.partition.read.idle_milliseconds_max` `GAUGE`, milliseconds	Maximum idle time (how long the partition has not been read from) across all partitions. Labels: - *topic* – topic name. - *consumer* – consumer name.
`topic.partition.read.lag_milliseconds_max` `GAUGE`, milliseconds	Difference between the current time and the minimum write time among all messages read in the last minute across all partitions. Labels: - *topic* – topic name. - *consumer* – consumer name.
`topic.partition.write.lag_milliseconds_max` `GAUGE`, milliseconds	Maximum difference between the write time and the creation time among all messages written in the last minute. Labels: - *topic* – topic name.
`topic.partition.write.speed_limit_bytes_per_second` `GAUGE`, bytes per second	Write quota in bytes per second per partition. Labels: - *topic* – topic name.
`topic.partition.write.throttled_nanoseconds_max` `GAUGE`, nanoseconds	Maximum write throttling time (waiting on quota) across all partitions. In the limit, if `topic.partition.write.throttled_nanoseconds_max` = 10^9, it means waiting on quota for the entire second. Labels: - *topic* – topic name.

`topic.partition.write.bytes_per_day_max` `GAUGE`, bytes	Maximum number of bytes written in the last 24 hours across all partitions. Labels: - *topic* – topic name.
`topic.partition.write.bytes_per_hour_max` `GAUGE`, bytes	Maximum number of bytes written in the last hour across all partitions. Labels: - *topic* – topic name.
`topic.partition.write.bytes_per_minute_max` `GAUGE`, bytes	Maximum number of bytes written in the last minute across all partitions. Labels: - *topic* – topic name.
`topic.partition.write.idle_milliseconds_max` `GAUGE`, milliseconds	Maximum partition write idle time. Labels: - *topic* – topic name.

Resource pool metrics

Metric name Type, units	Description Labels
`kqp.workload_manager.CpuQuotaManager.AverageLoadPercentage` `RATE`, units	Average database load, `DATABASE_LOAD_CPU_THRESHOLD` operates based on this metric.
`kqp.workload_manager.InFlightLimit` `GAUGE`, units	Limit on the number of concurrently running queries.
`kqp.workload_manager.GlobalInFly` `GAUGE`, units	Current number of concurrently running queries. Displayed only for pools with `CONCURRENT_QUERY_LIMIT` or `DATABASE_LOAD_CPU_THRESHOLD` enabled.
`kqp.workload_manager.QueueSizeLimit` `GAUGE`, units	Size of the queue of queries waiting to be executed.
`kqp.workload_manager.GlobalDelayedRequests` `GAUGE`, units	Number of queries waiting in the execution queue. Displayed only for pools with `CONCURRENT_QUERY_LIMIT` or `DATABASE_LOAD_CPU_THRESHOLD` enabled.

Grafana dashboards for YDB

This page describes Grafana dashboards for YDB.

Instructions on how to install and configure dashboards are provided in the YDB cluster monitoring setup section.

DB status

General database dashboard.

Download the **DB status** dashboard template: dbstatus.json.

DB overview

General database dashboard by categories:

- Health
- API
- API details
- CPU
- CPU pools
- Memory
- Storage
- DataShard
- DataShard details
- Latency

Download the **DB overview** dashboard template: dboverview.json.

YDB Essential Metrics

Dashboard for monitoring key database metrics.

Health section

This section contains charts showing the status of cluster and database components.

Name	Description
Nodes count	Number of running YDB nodes, pcs.
Nodes uptime	Uptime of each node since startup; helps detect restarts and unstable nodes, in seconds.
VDisks count	Number of available VDisks in the cluster, pcs.

Saturation section

This section contains charts reflecting database resource utilization.

Name	Description
CPU by thread pool (dynnodes)	CPU consumption by dynamic nodes per execution pool, in CPU cores.
CPU utilization (dynnodes)	CPU utilization by dynamic nodes per execution pool, in %.
Elapsed Time vs CPU Time	Ratio of real operation execution time (`ElapsedMicrosec`) to CPU time (`CpuMicrosec`) by node. A sustained excess above 100% means sessions are spending time waiting rather than actively working: typically, this is I/O wait or CPU overcommit on the hypervisor side.
RSS size by node	Amount of RAM (Resident set size) consumed by each dynamic node, showing cgroup memory limits, in bytes.
Storage usage	Logical database size and its configured limit, in bytes.
Overloaded shard count	Number of overloaded DataShards by CPU load ranges — from 50% to 100%, pcs.

Traffic section

This section contains charts characterizing database load.

Name	Description
Queries per second by latency buckets	Number of queries per second broken down by latency ranges (from 1 ms to +∞). Each range is highlighted with a separate color — from green for fast queries to purple for slow ones. Allows you to estimate latency distribution and overall RPS, in qps.
Transactions per second by latency buckets	Number of transactions per second broken down by latency ranges (from 1 ms to +∞). Each range is highlighted with a separate color — from green for fast transactions to purple for slow ones. Allows you to estimate latency distribution and overall TPS, in tps.
Rows read, uploaded, updated, deleted	Number of table row operations per second: read, create, update, and delete, in ops/s.
Session count by dynnode	Number of active sessions on each dynamic node, pcs.

Latency section

This section contains charts showing query and transaction execution times.

Name	Description
Query latency percentiles (ms)	Database query execution time at percentiles p50, p90, p95, p99, in milliseconds.
Transaction latency percentiles (ms)	Database transaction execution time at percentiles p50, p90, p95, p99, in milliseconds.

Errors section

This section contains charts showing the number of errors occurring.

Name	Description
YQL Issues per second	Number of YQL query execution errors by error type, in errors/s.
gRPC response errors per second	Number of gRPC responses with errors broken down by status, in errors/s.

Download the **YDB Essential Metrics** dashboard template: ydb-essentials.json.

Actors

CPU consumption in the actor system.

Name	Description
CPU by execution pool (us)	CPU consumption in various execution pools on all nodes, microseconds per second (one million corresponds to one core consumption).
Actor count	Number of actors (by actor type).
CPU	CPU consumption in various execution pools (by actor type).
Events	Event processing metrics in the actor system.

Download the **Actors** dashboard template: actors.json.

CPU

CPU consumption in execution pools.

Name	Description
CPU by execution pool	CPU consumption in various execution pools on all nodes, microseconds per second (one million corresponds to consumption of one core)
Actor count	Number of actors (by actor type)
CPU	CPU consumption in various execution pools
Events	Event processing metrics in various execution pools

Download the **CPU** dashboard template: cpu.json.

gRPC

gRPC layer metrics.

Name	Description
Requests	Number of requests received by the database per second (by gRPC method type)
Request bytes	Size of requests received by the database, bytes per second (by gRPC method type)
Response bytes	Size of responses sent by the database, bytes per second (by gRPC method type)
Dropped requests	Number of requests per second whose processing was terminated at the transport layer due to an error (by gRPC method type)
Dropped responses	Number of responses per second whose sending was terminated at the transport layer due to an error (by gRPC method type)
Requests in flight	Number of requests being processed simultaneously by the database (by gRPC method type)
Request bytes in flight	Size of requests being processed simultaneously by the database (by gRPC method type)

Download the **gRPC** dashboard template: grpc.json.

Query engine

Information about the query execution engine.

Name	Description
Requests	Number of incoming requests per second (by query type)
Request bytes	Size of incoming requests, bytes per second (`query, parameters, total`)
Responses	Number of responses per second (by response type)
Response bytes	Response sizes, bytes per second (`total, query result`)

Sessions	Information about established sessions
Latencies	Histograms of query execution times for various query types

Download the **Query engine** dashboard template: queryengine.json.

TxProxy

Information about transactions from the `DataShard transaction proxy` level.

Name	Description
Transactions	Metrics of datashard transactions
Latencies	Histograms of execution times of various stages of datashard transactions

Download the **TxProxy** dashboard template: txproxy.json.

DataShard

Metrics of the `DataShard` tablet.

Name	Description
Operations	Statistics of operations with the datashard for different operation types
Transactions	Information about transactions of the datashard tablet (by transaction types)
Latencies	Histograms of execution times of various stages of user transactions
Tablet latencies	Histograms of execution times of tablet transactions
Compactions	Information about performed LSM compaction operations
ReadSets	Information about transferred ReadSets during execution of a user transaction
Other	Other metrics

Download the **DataShard** dashboard template: datashard.json.

Database Hive

Metrics of the Hive tablet of the selected database.

The dashboard contains the following filters:

- `database` — used to select the database whose metrics should be displayed;
- `ds` — used to select the Prometheus source whose data should be displayed on the dashboard;
- `Tx type` — determines the transaction type for which graphs will be displayed on the "`{Tx type}` `average time`" panel.

Name	Description
CPU usage by HIVE_ACTOR, HIVE_BALANCER_ACTOR	CPU time consumed by `HIVE_ACTOR` and `HIVE_BALANCER_ACTOR` — the two most important Hive actors.
Self-ping time	Response time of the Hive tablet to its own requests. High values indicate heavy load (and slow responsiveness) of Hive.
Local transaction times	CPU time consumed for executing various types of local transactions in Hive. Displays the load structure on Hive.
Tablet count	Total number of tablets in the database.
Event queue size	Size of the incoming event queue. Consistently high values indicate that Hive is not keeping up with processing events at the required speed.
{Tx type} average time	Average execution time of one local transaction of the type selected in the `Tx type` filter.
Versions	Versions of YDB running on cluster nodes.
Hive node	Node on which Hive is running.

Download the **Database Hive** dashboard template: database-hive-detailed.json.

Topic

The dashboard displays graphs for metrics of a single topic. The topic name is set in the `topic` filter at the top of the dashboard. Below are the panels and metric descriptions.

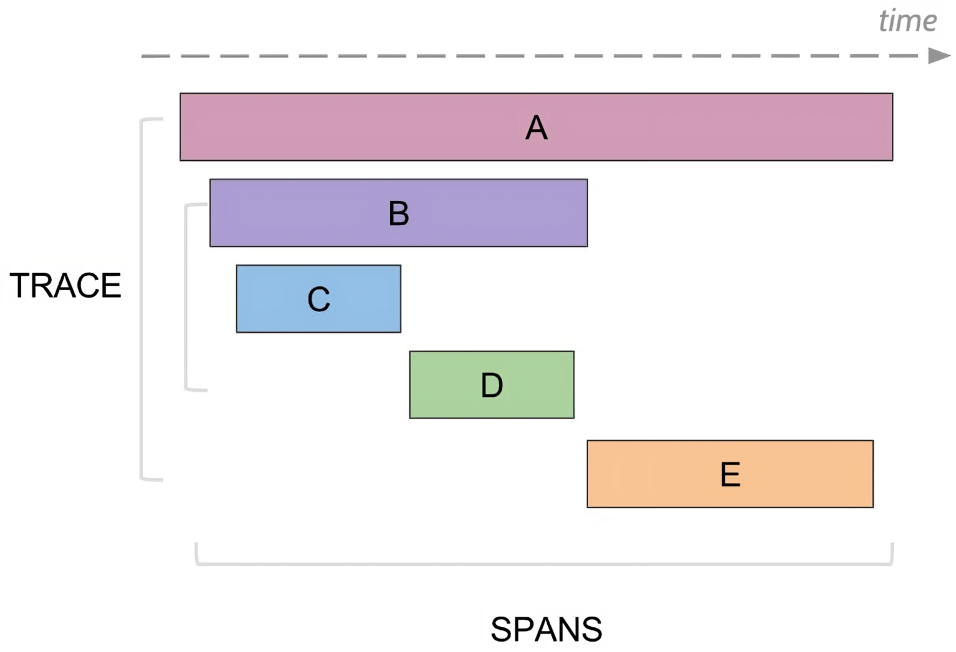
Name	Description
Total incoming records (bytes) per second	Number of bytes per second written to the topic using the `Ydb::TopicService::StreamWrite` method
Total incoming records (count) per second	Number of messages per second written using the `Ydb::TopicService::StreamWrite` method
Write latency	Write latency: time from message creation to its write to the topic. Percentage of messages for which write latency falls within intervals <100 ms, <200 ms, etc.

Partition throttling	Write throttling duration - waiting for available write quota. Percentage of messages for which write throttling duration falls within intervals <1 ms, <5 ms, etc.
Partition quota usage	Utilization of topic partition write quotas, %
Write sessions active	Number of open write sessions to the topic
Write sessions created	Number of write sessions created per second to the topic

Download the **Topic** dashboard template: topic.json.

Topic — Consumer

The dashboard displays graphs for the metrics of a single topic and its associated consumer. The topic is selected in the `topic` filter, and the consumer in the `consumer` filter. The panels and metric descriptions are listed below.



Name	Description
Total incoming records (bytes) per second	Number of bytes per second written to the topic using the `Ydb::TopicService::StreamWrite` method
Total outgoing records (bytes) per second	Number of bytes per second read from the topic by the consumer using the `Ydb::TopicService::StreamRead` method
Total incoming records (count) per second	Number of messages per second written to the topic using the `Ydb::TopicService::StreamWrite` method
Total outgoing records (count) per second	Number of messages per second read from the topic by the consumer using the `Ydb::TopicService::StreamRead` method
End-to-end latency	End-to-end latency: time from message creation to its read. Percentage of messages for which end-to-end latency falls within intervals <100 ms, <200 ms, etc.
Read latency max	Maximum (across all partitions) difference between the current time and the write time of the last message in the topic, ms
Unread messages max	Maximum (across all partitions) difference between the last offset in the partition and the last read offset, in messages
Read idle time max	Maximum idle time (how long the consumer has not read from the partition) across all topic partitions, ms
Uncommitted messages max	Maximum (across all partitions) difference between the last offset in the partition and the last committed offset, in messages
Committed read lag max	Maximum (across all partitions) difference between the current time and the write time of the last committed message in the topic, ms
Partition sessions started	Number of topic read sessions started by the consumer per second

Download the **Topic — Consumer** dashboard template: topic-consumer.json.

Tracing in YDB

> **Note**
>
> The OpenTelemetry website describes the concept of tracing in detail in the Observability Primer article.

Tracing is a tool that allows you to view the detailed path of a request through a distributed system. A set of spans describes the path of a single request (trace). A span is a time segment usually associated with the execution time of a specific operation (e.g., writing information to disk or executing a transaction). Spans form a tree, often with the subtree of a span as its detail, but this is not always the case.

To aggregate disparate spans into traces, they are sent to a *collector*. This service aggregates and stores received spans for subsequent trace analysis. YDB does not include this service; the administrator must set it up independently. Typically, Jaeger is used as a collector.

Minimal configuration

To enable tracing in YDB, add the following section to the configuration:

```
tracing_config:
  backend:
    opentelemetry:
      collector_url: grpc://example.com:4317
      service_name: ydb
  external_throttling:
    - max_traces_per_minute: 10
```

Here, the `collector_url` field sets the URL of an OTLP-compatible span collector. More details on the backend section can be found in the relevant section.

With this configuration, no requests are sampled, and no more than ten requests per minute with an external trace-id are traced by each cluster node.

Section descriptions

Backend

Example section

```
tracing_config:
  # ...
  backend:
    opentelemetry:
      collector_url: grpc://example.com:4317
      service_name: ydb
```

Description

This section describes the span collector. Currently, the only option is `opentelemetry`. Spans are pushed from the cluster node to the collector, requiring the collector to be OTLP compatible.

In the `opentelemetry` section:

- `collector_url` — the URL of the span collector. The scheme can be either `grpc://` for an insecure connection or `grpcs://` for a TLS connection.
- `service_name` — the name under which all spans will be marked.

Both parameters are mandatory.

Uploader

Example section

```
tracing_config:
  # ...
  uploader:
    max_exported_spans_per_second: 30
    max_spans_in_batch: 100
    max_bytes_in_batch: 10485760 # 10 MiB
    max_export_requests_inflight: 3
    max_batch_accumulation_milliseconds: 5000
    span_export_timeout_seconds: 120
```

Description

The uploader is a cluster node component responsible for sending spans to the collector. To avoid overloading the span collector, the uploader will not send more than `max_exported_spans_per_second` spans per second on average.

For optimization, the uploader sends spans in batches. Each batch contains no more than `max_spans_in_batch` spans with a total serialized size of no more than `max_bytes_in_batch` bytes. Each batch accumulates for no more than `max_batch_accumulation_milliseconds` milliseconds. Batches can be sent in parallel, with the maximum number of simultaneously sent batches controlled by the `max_export_requests_inflight` parameter. If more than `span_export_timeout_seconds` seconds have passed since the uploader received the span, the uploader may delete it to send fresher spans.

Default values:

- `max_exported_spans_per_second = inf` (no limits)
- `max_spans_in_batch = 150`
- `max_bytes_in_batch = 20000000`
- `max_batch_accumulation_milliseconds = 1000`
- `span_export_timeout_seconds = inf` (no spans are deleted by the uploader)
- `max_export_requests_inflight = 1`

The `uploader` section may be completely absent, in which case each parameter will use its default value.

> **Note**
>
> The uploader is a node-local component. Therefore, the described limits apply to each node separately, not to the entire cluster.

External throttling

Example section

```
tracing_config:
  # ...
  external_throttling:
    - scope:
        database: /Root/db1
      max_traces_per_minute: 60
      max_traces_burst: 3
```

Description

YDB supports the transmission of external trace-ids to build a coherent request trace. The method for transmitting an external trace-id is described on the Passing external trace-id to YDB page. To avoid overloading the collector, YDB has a mechanism to limit the number of externally traced requests. The limits are described in this section and are a sequence of rules. Each rule contains:

- `scope` – a set of selectors for filtering the request.
- `max_traces_per_minute` – the maximum average number of requests per minute traced by this rule. A positive integer is expected.
- `max_traces_burst` – the maximum burst of externally traced requests. A non-negative integer is expected.

The only mandatory parameter is `max_traces_per_minute`.

A detailed description of these options is provided in the Rule semantics section.

The `external_throttling` section is not mandatory; if it is absent, all trace-ids in requests are **ignored** (no external traces are continued).

This section can be modified without restarting the node using the dynamic configuration mechanism.

Sampling

Example section

```
tracing_config:
  # ...
  sampling:
    - fraction: 0.01
      level: 10
      max_traces_per_minute: 5
      max_traces_burst: 2
    - scope:
        request_types:
          - KeyValue.ExecuteTransaction
          - KeyValue.Read
      fraction: 0.1
      level: 15
      max_traces_per_minute: 5
      max_traces_burst: 2
```

Description

For diagnosing system issues, looking at a sample request trace can be useful regardless of whether users trace their requests or not. For this purpose, YDB has a request sampling mechanism. For a sampled request, a random trace-id is generated. This section controls request sampling in a format similar to `external_throttling`. Each rule has two additional fields:

- `fraction` – the fraction of requests sampled by this rule. A floating-point number between 0 and 1 is expected.
- `level` — the detail level of the trace. An integer from 0 to 15 is expected. This parameter is described in more detail in the Detail levels section.

Both fields are mandatory.

The `sampling` section is not mandatory; no requests will be sampled if it is absent.

This section can be modified without restarting the node using the dynamic configuration mechanism.

Rule semantics

Selectors

Each rule includes an optional `scope` field with a set of selectors that determine which requests the rule applies to. Currently, the supported selectors are:

- `request_types`

  Accepts a list of request types. A request matches this selector if its type is in the list.

Possible values

- KeyValue.CreateVolume
- KeyValue.DropVolume
- KeyValue.AlterVolume
- KeyValue.DescribeVolume
- KeyValue.ListLocalPartitions
- KeyValue.AcquireLock
- KeyValue.ExecuteTransaction
- KeyValue.Read
- KeyValue.ReadRange
- KeyValue.ListRange

> **Note**
>
> Tracing is supported not only for the request types listed above. This list includes request types that are supported by the `request_types` selector.

> **Warning**
>
> Note that the QueryService API is experimental and may change in the future.

- `database`

  Filters requests to the specified database.

A request matches a rule if it matches all selectors. `scope` can be absent, which is equivalent to an empty set of selectors, and all requests will fall under this rule.

Rate limiting

The `max_traces_per_minute` and `max_traces_burst` parameters limit the number of requests. In the case of sampling, they limit the number of requests sampled by this rule. In the case of external throttling, they limit the number of external traces that enter the system.

A variation of the leaky bucket is used for rate limiting with a bucket size equal to `max_traces_burst + 1`. For example, if `max_traces_per_minute = 60` and `max_traces_burst = 0`, then with a flow of 10,000 requests per minute, one request will be traced every second. If `max_traces_burst = 20`, then with the same request flow, the first 21 requests will be traced, and then one request per second will be traced.

> **Warning**
>
> The limits on the number of traced requests are local to the cluster node. For example, if each cluster node has a rule specifying `max_traces_per_minute = 1`, then no more than one request per minute will be traced **from each cluster node** by this rule.

Detail levels

As with logs, diagnosing most system issues does not require the most detailed trace. Therefore, in YDB, each span has its own level described by an integer from 0 to 15 inclusive. Each rule in the `sampling` section must include the detail level of the generated trace (`level`); spans with a level less than or equal to `level` will be included in it.

The YDB architecture section describes the system's division into 5 layers:

Layer	Components
1	gRPC Proxies
2	Query Processor
3	Distributes Transactions
4	Tablet, System tablet
5	Distributed Storage

Each layer has seven detail levels:

Level	Value
`Off`	No tracing
`TopLevel`	Lowest detail, no more than two spans per request to the component
`Basic`	Spans of main component operations
`Detailed`	Highest detail applicable for diagnosing problems in production
`Diagnostic`	Detailed debugging information for developers
`Trace`	Very detailed debugging information

The table below shows the distribution of system layer detail levels by trace detail levels:

Trace detail level	gRPC Proxies	Query Processor	Distributed Transactions	Tablets	Distributed Storage
0	`TopLevel`	`Off`	`Off`	`Off`	`Off`
1	`TopLevel`	**`TopLevel`**	`Off`	`Off`	`Off`
2	`TopLevel`	`TopLevel`	**`TopLevel`**	`Off`	`Off`
3	`TopLevel`	`TopLevel`	`TopLevel`	**`TopLevel`**	`Off`
4	`TopLevel`	`TopLevel`	`TopLevel`	`TopLevel`	**`TopLevel`**
5	**`Basic`**	`TopLevel`	`TopLevel`	`TopLevel`	`TopLevel`
6	`Basic`	**`Basic`**	`TopLevel`	`TopLevel`	`TopLevel`
7	`Basic`	`Basic`	**`Basic`**	`TopLevel`	`TopLevel`
8	`Basic`	`Basic`	`Basic`	**`Basic`**	`TopLevel`
9	`Basic`	`Basic`	`Basic`	`Basic`	**`Basic`**
10	**`Detailed`**	**`Detailed`**	`Basic`	`Basic`	`Basic`
11	`Detailed`	`Detailed`	**`Detailed`**	`Basic`	`Basic`
12	`Detailed`	`Detailed`	`Detailed`	**`Detailed`**	`Basic`
13	`Detailed`	`Detailed`	`Detailed`	`Detailed`	**`Detailed`**
14	**`Diagnostic`**	**`Diagnostic`**	**`Diagnostic`**	**`Diagnostic`**	**`Diagnostic`**
15	**`Trace`**	**`Trace`**	**`Trace`**	**`Trace`**	**`Trace`**

Rules

External throttling

The semantics of each rule are as follows: it allocates a quota for the number of requests in this category. For example, if the `external_throttling` section looks like this:

```
tracing_config:
  external_throttling:
    - max_traces_per_minute: 60
    - scope:
        request_types:
          - KeyValue.ReadRange
      max_traces_per_minute: 20
```

With a sufficient flow of requests with an external trace-id, at least 60 requests per minute and at least 20 `KeyValue.ReadRange` type requests per minute will be traced. A total of up to 80 requests per minute will be traced.

The algorithm is as follows: for a request with an external trace-id, the rules that apply to this request are determined. The request consumes the quota of all rules that still have it. The request is not traced only if none of the rules have any quota left.

Sampling

The semantics of the rule for sampling are similar: with a sufficiently low flow of requests in this category, at least a `fraction` of the requests with at least `level` detail will be sampled.

The algorithm is similar: the set of rules that apply to this request is determined for a request without an external trace-id (either due to its initial absence or due to a previous decision not to trace this request). The request consumes the quota of all rules that still have it and that have randomly "decided" to sample it. It is not sampled if no rule decides to sample the request (all rules that "decided" to sample the request have no quota left). Otherwise, the detail level is determined as the maximum among the rules into whose quota the request fell.

For example, with the following `sampling` configuration:

```
tracing_config:
  sampling:
    - scope:
        database: /Root/db1
      fraction: 0.5
      level: 5
      max_traces_per_minute: 100
    - scope:
        database: /Root/db1
      fraction: 0.01
      level: 15
      max_traces_per_minute: 5
```

With a sufficiently low flow of requests to the `/Root/db1` database, the following will be sampled:

- 1% of requests with a detail level of 15
- 49.5% of requests with a detail level of 5

With a sufficiently high flow of requests to the `/Root/db1` database, the following will be sampled:

- 5 requests per minute with a detail level of 15
- between 95 and 100 requests per minute with a detail level of 5

Passing external trace-id to YDB

gRPC API

YDB supports passing external trace-id to build a complete operation trace. The trace-id is passed according to the trace context specification — a string of the form `00-0af7651916cd43dd8448eb211c80319c-b7ad6b7169203331-01` must be passed through the `traceparent` header of the gRPC request. It consists of 4 parts separated by the `-` character:

1. Version – at the time of writing, the specification defines only version 00.
2. Trace id – the identifier of the trace that the request is part of.
3. Parent id – the identifier of the parent span.
4. Flags – a set of recommendations for handling the data passed in the header.

Only version 00 is supported; flags are ignored. If the header does not conform to the specification, it is ignored. All traces obtained this way have detail level 13 (all components are traced at level `Detailed`).

> **Warning**
>
> If the `external_throttling` section is present and the request flow exceeds the set limits, not all requests may be traced. If the `external_throttling` section is absent, the `traceparent` header is **ignored** and no external traces are continued.

SDK support

Some SDKs support trace-id passing; you can find their list and usage examples on the Tracing with OpenTelemetry page.

YDB DSTool overview

With the YDB DSTool utility, you can manage your YDB cluster's disk subsystem. To install and configure the utility, follow the instructions.

YDB DSTool includes the following commands:

Command	Description
device list	List storage devices.
pdisk add-by-serial	Add a PDisk to a set by serial number.
pdisk remove-by-serial	Remove a PDisk from the set by serial number.
pdisk set	Set PDisk parameters.
pdisk list	List PDisks.
pdisk populate	Place the same VDisks on another PDisk for device testing.
vdisk evict	Move VDisks to different PDisks.
vdisk remove-donor	Remove a donor VDisk.
vdisk wipe	Wipe VDisks.
vdisk list	List VDisks.
group add	Add storage groups to a pool.
group check	Check storage groups.
group show blob-info	Display blob information.
group show usage-by-tablets	Display information about tablet usage by groups.
group state	Show or change a storage group's state.
group take-snapshot	Take a snapshot of storage group metadata.
group list	List storage groups.
pool list	List pools.
box list	List sets of PDisks.
node list	List nodes.
cluster balance	Move VDisks from overloaded PDisks.
cluster get	Show cluster parameters.
cluster set	Set cluster parameters.
cluster workload run	Run a workload to test the failure model.
cluster list	Display cluster information.

YDB DSTool overview

With the YDB DSTool utility, you can manage your YDB cluster's disk subsystem. To install and configure the utility, follow the instructions.

YDB DSTool includes the following commands:

Command	Description
device list	List storage devices.
pdisk add-by-serial	Add a PDisk to a set by serial number.
pdisk remove-by-serial	Remove a PDisk from the set by serial number.
pdisk set	Set PDisk parameters.
pdisk list	List PDisks.
pdisk populate	Place the same VDisks on another PDisk for device testing.
vdisk evict	Move VDisks to different PDisks.
vdisk remove-donor	Remove a donor VDisk.
vdisk wipe	Wipe VDisks.
vdisk list	List VDisks.
group add	Add storage groups to a pool.
group check	Check storage groups.
group show blob-info	Display blob information.
group show usage-by-tablets	Display information about tablet usage by groups.
group state	Show or change a storage group's state.
group take-snapshot	Take a snapshot of storage group metadata.
group list	List storage groups.
pool list	List pools.
box list	List sets of PDisks.
node list	List nodes.
cluster balance	Move VDisks from overloaded PDisks.
cluster get	Show cluster parameters.
cluster set	Set cluster parameters.
cluster workload run	Run a workload to test the failure model.
cluster list	Display cluster information.

Installing the YDB DSTool

Linux

To install the YDB DSTool, follow these steps:

1. Run the command:

   ```
   curl -sSL 'https://install.ydb.tech/dstool' | bash
   ```

   The script will install the YDB DSTool. If the script is run from a `bash` or `zsh` shell, it will also add the `ydb-dstool` executable to the `PATH` environment variable. Otherwise, you can run it from the `~/ydb/bin` folder or add it to `PATH` manually.
2. To update the environment variables, restart the command shell.
3. Test it by running the command that shows cluster information:

   ```
   ydb-dstool -e <bs_endpoint> cluster list
   ```

   - `bs_endpoint`: URI of the cluster's HTTP endpoint, the same endpoint that serves the YDB UI. Example: `http://localhost:8765`.

   Result:

   ```
   ┌───────┬───────┬───────┬────────┬────────┬───────┬────────┐
   | Hosts | Nodes | Pools | Groups | VDisks | Boxes | PDisks |
   ├───────┼───────┼───────┼────────┼────────┼───────┼────────┤
   | 8     | 16    | 1     | 5      | 40     | 1     | 32     |
   └───────┴───────┴───────┴────────┴────────┴───────┴────────┘
   ```

macOS

To install the YDB DSTool, follow these steps:

1. Run the command:

   ```
   curl -sSL 'https://install.ydb.tech/dstool' | bash
   ```

   The script will install the YDB DSTool. If the script is run from a `bash` or `zsh` shell, it will also add the `ydb-dstool` executable to the `PATH` environment variable. Otherwise, you can run it from the `~/ydb/bin` folder or add it to `PATH` manually.
2. To update the environment variables, restart the command shell.
3. Test it by running the command that shows cluster information:

   ```
   ydb-dstool -e <bs_endpoint> cluster list
   ```

   - `bs_endpoint`: URI of the cluster's HTTP endpoint, the same endpoint that serves the YDB UI. Example: `http://localhost:8765`.

   Result:

   ```
   ┌───────┬───────┬───────┬────────┬────────┬───────┬────────┐
   | Hosts | Nodes | Pools | Groups | VDisks | Boxes | PDisks |
   ├───────┼───────┼───────┼────────┼────────┼───────┼────────┤
   | 8     | 16    | 1     | 5      | 40     | 1     | 32     |
   └───────┴───────┴───────┴────────┴────────┴───────┴────────┘
   ```

Windows

To install the YDB DSTool, follow these steps:

1. Run the command:
   - in **PowerShell**:

     ```
     iex (New-Object System.Net.WebClient).DownloadString('https://install.ydb.tech/dstool-windows')
     ```

   - in **CMD**:

     ```
     @"%SystemRoot%\System32\WindowsPowerShell\v1.0\powershell.exe" -Command "iex ((New-Object System.Ne
     t.WebClient).DownloadString('https://install.ydb.tech/dstool-windows'))"
     ```

2. Specify whether to add `ydb-dstool` to the `PATH` environment variable:

   ```
   Add ydb-dstool installation dir to your PATH? [Y/n]
   ```

3. To update the environment variables, restart the command shell.

> **Note**
>
> The YDB DSTool uses Unicode characters in the output of some commands. If these characters aren't displayed correctly in the Windows console, switch the encoding to UTF-8:
>
> ```
> chcp 65001
> ```

4. Test it by running the command that shows cluster information:

```
ydb-dstool -e <bs_endpoint> cluster list
```

   - `bs_endpoint` : URI of the cluster's HTTP endpoint, the same endpoint that serves the YDB UI. Example: `http://localhost:8765`.

   Result:

```
┌───────┬───────┬───────┬────────┬────────┬───────┬────────┐
| Hosts | Nodes | Pools | Groups | VDisks | Boxes | PDisks |
├───────┼───────┼───────┼────────┼────────┼───────┼────────┤
| 8     | 16    | 1     | 5      | 40     | 1     | 32     |
└───────┴───────┴───────┴────────┴────────┴───────┴────────┘
```

Global options

All the YDB DSTool utility subcommands share the same global options.

Option	Description
`-?`, `-h`, `--help`	Print the built-in help.
`-v`, `--verbose`	Print detailed output while executing the command.
`-q`, `--quiet`	Suppress non-critical messages when executing the command.
`-n`, `--dry-run`	Dry-run the command.
`-e`, `--endpoint`	Endpoint to connect to the YDB cluster, in the format: `[PROTOCOL://]HOST[:PORT]`. Default values: PROTOCOL — `http`, PORT — `8765`.
`--grpc-port`	gRPC port used to invoke procedures.
`--mon-port`	Port to view HTTP monitoring data in JSON format.
`--mon-protocol`	If you fail to specify the cluster connection protocol explicitly in the endpoint, the protocol is taken from here.
`--token-file`	Path to the file with Access Token.
`--ca-file`	Path to a root certificate PEM file used for TLS connections.
`--http`	Use HTTP instead of gRPC to connect to the Blob Storage.
`--http-timeout`	Timeout for I/O operations on the socket when running HTTP(S) queries.
`--insecure`	Allow insecure data delivery over HTTPS. Neither the SSL certificate nor host name are checked in this mode.

device list

Use the `device list` subcommand to get a list of storage devices available on the YDB cluster.

General format of the command:

```
ydb-dstool [global options ...] device list [list options ...]
```

- `global options` : Global options.
- `list options` : Subcommand options.

View a description of the command to get a list of devices:

```
ydb-dstool device list --help
```

Subcommand options

Option	Description
`-H`, `--human-readable`	Output data in human-readable format.
`--sort-by`	Sort column. Use one of the values: `SerialNumber`, `FQDN`, `Path`, `Type`, `StorageStatus`, or `NodeId:PDiskId`.
`--reverse`	Use a reverse sort order.
`--format`	Output format. Use one of the values: `pretty`, `json`, `tsv`, or `csv`.
`--no-header`	Do not output the row with column names.
`--columns`	List of columns to be output. Use one or more of the values: `SerialNumber`, `FQDN`, `Path`, `Type`, `StorageStatus`, or `NodeId:PDiskId`.
`-A`, `--all-columns`	Output all columns.

Examples

The following command will output a list of devices available in the cluster:

```
ydb-dstool -e node-5.example.com device list
```

Result:

```
┌──────────────────────┬──────────────────────┬──────────────────────────────────┬──────┬──────────────────────────────
─┬──────────────────┐
| SerialNumber       | FQDN                 | Path                             | Type | StorageStatus
| NodeId:PDiskId |
├──────────────────────┼──────────────────────┼──────────────────────────────────┼──────┼──────────────────────────────
─┼──────────────────┤
| PHLN123301H41P2BGN | node-1.example.com | /dev/disk/by-partlabel/nvme_04 | NVME | FREE
| NULL           |
| PHLN123301A62P2BGN | node-6.example.com | /dev/disk/by-partlabel/nvme_03 | NVME | PDISK_ADDED_BY_DEFINE_BOX
| [6:1001]       |
...
```

pdisk populate

Use the `pdisk populate` subcommand to move a selected set of VDisks to one PDisk. The command can save the active VDisks of a source PDisk to a snapshot file and then use that file to populate a destination PDisk.

> **Warning**
>
> Use `pdisk populate` for controlled device testing: it lets you place exactly the same set of VDisks on a new device and compare how the old and new devices handle that workload.

The Blob Storage Controller validates all selected VDisks and schedules their reassignment in a single atomic configuration transaction. If any VDisk cannot be reassigned, the configuration is not changed. The data migration itself continues asynchronously after the transaction is applied.

General format of the command:

```
ydb-dstool [global options ...] pdisk populate [populate options ...]
```

- `global options` : Global options.
- `populate options`: Subcommand options.

View a description of the command:

```
ydb-dstool pdisk populate --help
```

Subcommand options

Option	Description
`--snapshot-from-pdisk <NodeId:PDiskId>`	Snapshot mode. Collect active VDisks from the specified PDisk. Donor VDisks are skipped.
`-d`, `--destination-pdisk <NodeId:PDiskId>`	Populate mode. Move the VDisks listed in `--snapshot-file` to the specified PDisk.
`--snapshot-file <PATH>`	In snapshot mode, write the VDisk list as JSON to the specified file. In populate mode, read the VDisk list from this file. This option is required in populate mode.
`--suppress-donor-mode`	Do not leave the previous VDisk locations in donor mode after reassignment. This option is only available in populate mode.
`--format <FORMAT>`	Output format: `pretty` (default) or `json`.

Exactly one of `--snapshot-from-pdisk` and `--destination-pdisk` must be specified.

Example

First, save the list of active VDisks on PDisk `[1:1000]` to a snapshot file:

```
ydb-dstool -e node-1.example.com pdisk populate \
  --snapshot-from-pdisk '[1:1000]' \
  --snapshot-file /tmp/pdisk-1-1000.json
```

The snapshot file has the following format:

```
{
  "pdisk_id": "[1:1000]",
  "vdisk_ids": [
    "[80000001:_:0:0:0]",
    "[80000002:_:0:1:0]"
  ]
}
```

Review the snapshot and then move the listed VDisks to PDisk `[2:1000]`:

```
ydb-dstool -e node-1.example.com pdisk populate \
  --destination-pdisk '[2:1000]' \
  --snapshot-file /tmp/pdisk-1-1000.json
```

The command skips VDisks with `GroupId=0`, because they cannot be migrated. If the snapshot contains only such VDisks, the command returns an error without changing the configuration.

ydbops utility overview

> **Note**
>
> The `ydbops` utility is under active development. Although backward-incompatible changes are unlikely, they may still occur.

`ydbops` utility automates some operational tasks on YDB clusters. It supports clusters deployed using Ansible, Kubernetes, or manually.

See also

- To install the utility, follow the instructions.
- See configuration reference for available configuration options.
- The source code of `ydbops` can be found on GitHub.

Currently supported scenarios

See the list of currently supported scenarios here.

Scenarios in development

- Requesting permission to take out a set of YDB nodes for maintenance without breaking YDB fault model invariants.

Scenarios in development

- Requesting permission to take out a set of YDB nodes for maintenance without breaking YDB fault model invariants.

Installing ydbops

> **Note**
>
> The `ydbops` utility is under active development. Although backward-incompatible changes are unlikely, they may still occur.

Download the binary from the releases page

You can download binary releases from Download YDB Ops.

Building from source

1. Clone the `ydbops` repository from GitHub:

   ```
   git clone https://github.com/ydb-platform/ydbops.git
   ```

2. There are two ways to build `ydbops`:
   2.1. Directly with Go
   2.2. Inside a Docker container

The second approach requires a prepared Docker environment and uses the official Docker image for Golang v1.22, guaranteeing a successful build. The Docker container operates using the `Dockerfile` from the repository. The build process in Docker also performs additional tasks: running linter checks and substituting the version for the `ydbops` assembly to register it in the executable file.

Building directly with Go

Prerequsites

Install Go. The recommended version is 1.22.

Compiling

Invoke `go build` in the repository root folder:

```
go build
```

The `ydbops` executable will be available in the repository root folder.

Installing

You can copy the executable file manually or use `make`:

```
make install INSTALL_DIR=install_folder BUILD_DIR=.
```

Inside a Docker container

Prerequsites

- make
- Install docker engine

Compiling

Invoke this command in the repository root folder:

```
make build-in-docker
```

The `ydbops` executables will be available in the `bin` folder. Binary files are generated for Linux and macOS (arm64, amd64).

Binary name	Platform
ydbops	Linux (amd64)
ydbops_darwin_amd64	macOS (amd64)
ydbops_darwin_arm64	macOS (arm64)

Installing

To install the binary file, execute the command `make`.

Optional parameters:

- `INSTALL_DIR`: The folder where the executable file will be installed. Default value: `~/ydb/bin`.
- `BUILD_DIR`: The folder that contains the generated executable file. Use this parameter if you created the executable file manually. For example, use `BUILD_DIR=.` if the executable file is in the current working directory.

```
make install [INSTALL_DIR=<path_to_install_folder>] [BUILD_DIR=<path_to_build_folder>]
```

Sample command to install into `install_folder` from the current folder:

```
make install INSTALL_DIR=install_folder BUILD_DIR=.
```

Configuring ydbops

> **Note**
>
> The `ydbops` utility is under active development. Although backward-incompatible changes are unlikely, they may still occur.

`ydbops` can be run by specifying all the necessary command line arguments on the command invocation. However, it has two features that allow to avoid repeating the commonly used arguments:

- Config file
- Environment variables

Config file

The configuration file for `ydbops` is a YAML-formatted file containing multiple profiles. Profiles for `ydbops` work in the same way as profiles in YDB CLI do.

Default configuration file location follows the same convention as YDB CLI does, it is located in the same folder in `ydbops` subdirectory. For comparison:

- default configuration file for YDB CLI: `$HOME/.ydb/config/config.yaml`
- default configuration file for `ydbops` CLI, `ydbops` subdirectory: `$HOME/ydb/ydbops/config/config.yaml`

Certain command line options can be written in the configuration file instead of being specified directly in the `ydbops` invocation.

Examples

Calling the `ydbops restart` command without a profile:

```
ydbops restart \
 -e grpc://<hostname>:2135 \
 --kubeconfig ~/.kube/config \
 --k8s-namespace <k8s-namespace> \
 --user admin \
 --password-file ~/<password-file> \
 --tenant --tenant-list=my-tenant
```

Calling the same `ydbops restart` command with profile options enabled makes the command much shorter:

```
ydbops restart \
 --config-file ./config.yaml \
 --tenant --tenant-list=<tenant-name>
```

For the invocation above, the following `config.yaml` is assumed to be present:

```
current-profile: my-profile
profiles:
  my-profile:
    endpoint: grpcs://<hostname>:2135
    ca-file: ~/<ca-certificate-file>
    user: <username>
    password-file: ~/<password-file>
    k8s-namespace: <k8s-namespace>
    kubeconfig: ~/.kube/config
```

Profile management commands

Currently, `ydbops` does not support the creation, modification, and activation of profiles via the CLI commands the way that YDB CLI does.

The configuration file needs to be created and edited manually.

Configuration file reference

Here is an example of a configuration file with all possible options that can be specified and example values (most likely, they will not all be needed at the same time):

```
# a special key `current-profile` can be specified to
# be used as the default active profile in the CLI invocation
current-profile: my-profile

# profile definitions are added as subkeys to the `profiles` key
profiles:
  my-profile:
    endpoint: grpcs://your.ydb.cluster.fqdn:2135

    # CA file location if using grpcs to the endpoint
    ca-file: /path/to/custom/ca/file

    # a username and password file if static credentials are used:
    user: your-ydb-user-name
    password-file: /path/to/password-file

    # when using access token
    token-file: /path/to/ydb/token

    # if working with YDB clusters in Kubernetes, kubeconfig path can be specified:
    kubeconfig: /path/to/kube/config
    k8s-namespace: <k8s-namespace>
```

Environment variables

Alternatively, there is an option to specify several environment variables instead of passing command-line arguments or using config files.

For an explanation of which options take precedence, please invoke `ydbops --help`.

- `YDB_TOKEN` can be passed instead of the `--token-file` flag or `token-file` profile option.
- `YDB_PASSWORD` can be passed instead of the `--password-file` flag or `password-file` profile option.
- `YDB_USER` can be passed instead of the `--user` flag or `user` profile option.

Performing YDB cluster restart using ydbops

> **Note**
>
> The `ydbops` utility is under active development. Although backward-incompatible changes are unlikely, they may still occur.

`ydbops` can be used to perform the rolling restart operation: restarting all or some of YDB cluster nodes while maintaining cluster availability. Why this is not trivial and requires a special utility is explained in the article about maintenance without downtime.

The subcommand responsible for this operation is `ydbops restart`.

General algorithm

There are multiple options for `ydbops restart` that act as filters. Filters are implicitly connected with a logical "and", meaning that if you supply multiple filters, only the nodes that satisfy all of them at once will be targeted. Therefore, specifying no filters targets all nodes for restart.

There are two special filters that are an exception to this rule, `--storage` and `--tenant`:

- Specifying only `--storage` will filter storage nodes only.
- Specifying only `--tenant` will filter tenant nodes only.
- However, specifying both selects all nodes and is equivalent to not specifying these two filters.

The algorithm will always work in two phases:

- First, it will determine whether any storage nodes fit the restart filters and restart these nodes only.
- After all storage nodes have been restarted or it has been determined that no storage nodes are selected, the process repeats for tenant nodes.

Examples

The following examples assume you have specified all the required connection options (such as endpoint or credentials).

Restarting all nodes in the cluster

The command will restart all the nodes in the cluster: all storage nodes first, followed by all tenant nodes.

```
ydbops restart
```

Restarting only storage or tenant nodes

It is possible to restart storage nodes only:

```
ydbops restart --storage
```

Or tenant nodes only:

```
ydbops restart --tenant
```

Additionally, only specific tenants may be restarted by specifying `--tenant-list`:

```
ydbops restart --tenant-list=</domain/database_name_1>,</domain/database_name_2>,...
```

Restarting only specific nodes

It is possible to restart nodes only on specific hosts by supplying FQDNs with the `--hosts` option:

```
ydbops restart --hosts=<node1.some.zone>,<node2.some.zone>
```

Or by supplying node ids directly:

```
ydbops restart --hosts=1,2,3
```

Restarting based on node uptime

It is possible to restart only the nodes that have specific uptime by using the `--started` option:

The option argument needs to be enclosed in quotes, otherwise shell might interpret `>` or `<` signs as stream redirections. See the example:

```
ydbops restart --started '>2024-03-13T17:00:00Z'
```

It might be convenient to restart only the nodes that have been up for over a few minutes, as the others have just restarted recently.

Restarting based on YDB version

It is possible to restart only the nodes whose version is equal to (`==`), not equal to (`!=`), greater than (`>`), or less than (`<`) the desired version.

The option argument needs to be enclosed in quotes; otherwise, the shell might interpret the `>` or `<` signs as stream redirections. See the examples:

```
ydbops restart --version '>24.1.2'
ydbops restart --version '<24.1.2'
ydbops restart --version '!=24.1.2'
ydbops restart --version '==24.1.2'
```

Hotfix versions (for example, `ydb-stable-24-1-14-hotfix-9`) have the same major, minor, and patch numbers as the corresponding non-hotfix version `24.1.14`.

For example, version `ydb-stable-24-1-14-hotfix-9` in comparison operations will be identical to version `ydb-stable-24-1-14`.

YDBOps Reference Sheet

ydbops options

Database Connection Options

DB connection options are described in Connecting to and authenticating with a database.

Service Options

- `--verbose`: increases output verbosity.
- `--profile-file`: use profiles from the specified file. By default, profiles from the `$HOME/ydb/ydbops/config/config.yaml file are used`.
- `--profile <string>`: override currently set profile name from `--profile-file`.
- `--grpc-timeout-seconds <int>`: wait this much time in seconds before timing out any GRPC requests (default 60).
- `--grpc-skip-verify`: do not verify server hostname when using gRPCs.
- `--ca-file <filepath>`: path to root ca file, appends to system pool.

Restart Options

- `--storage`: only include storage nodes. If no `--storage` or `--tenant` is specified, both `--storage` and `--tenant` become active, as it is assumed that the intention is to restart the whole cluster.
- `--tenant`: only include tenant nodes. Additionally, you can specify:
  - `--tenant-list=<tenant-name-1>,<tenant-name-2>`
- `--availability-mode <strong|weak|force>`: see the article about maintenance without downtime. Defaults to `strong`.
- `--restart-duration <int>`: multiplied by `--restart-retry-number`, this gives the total duration in seconds for the maintenance operation. In other words, it is a promise to CMS that a single node restart will finish within given duration. Defaults to 60 (which makes the default CMS request duration 180 seconds in combination with the default value of `--restart-retry-number`)
- `--restart-retry-number <int>`: if restarting a specific node failed, repeat the restart operation this much times. Defaults to 3.
- `--cms-query-interval <int>`: how often to query for updates from CMS while waiting for new nodes. Defaults to 10 seconds.
- `--nodes-inflight <int>`: the maximum number of nodes that are concurrently being restarted.
- `--delay-between-restarts <duration>`: delay before initiating the next node restart.

Filtering Options

Filtering options allow you to narrow down the list of nodes to restart.

- `--hosts <list>`: restart the following hosts. Hosts can be specified in multiple ways:
  - Using node ids: `--hosts=1,2,3`
  - Using host fqdns: `--hosts=<node1.some.zone>,<node2.some.zone>`
- `--exclude-hosts <list>`: do not restart the following hosts even if explicitly included. Syntax is the same as with the `--hosts` option.
- `--started '<sign><timestamp>'`: restart only the nodes that satisfy the particular uptime. Specify the sign (`<` or `>`) and a timestamp in ISO format to filter only the nodes that started before or after a particular timestamp. Be careful to enclose the timestamp with a sign in quotes, otherwise shell might interpret the sign as stream redirection.
  - example: `ydbops restart --started '>2024-03-13T17:00:00Z'`
- `--version '<sign><major>.<minor>.<patch>'`: restart only the nodes that satisfy the particular version filter. Specify the sign (`<`, `>`, `!=` or `==`), then specify the version by supplying three numbers: major, minor, patch versions. Be careful to enclose the timestamp with a sign in quotes, otherwise shell might interpret the sign as stream redirection.
  - example: `ydbops restart --version '>24.3.1'`
  - the command works with ydb processes that have their version in the following format: `ydb-stable-<major>-<minor>-<patch>.*`. Hotfix versions (e.g. `ydb-stable-24-1-14-hotfix-9`) have the same major, minor, patch numbers as their non-hotfix `24.1.14`. For example, `ydb-stable-24-1-14-hotfix-9` is treated in the same way as `ydb-stable-24-1-14`.

Kubernetes Options

If `--kubeconfig` is specified, it is assumed that the cluster to be restarted runs under Kubernetes, and node restart will be achieved by deleting pods as opposed to other ways of restart (e.g. systemd units).

- `--kubeconfig`: location to kubeconfig file which will be used for communicating with Kubernetes API (e.g. restarting nodes by deleting pods). There is no default value, since specifying this option also indicates Kubernetes mode.
- `--k8s-namespace`: namespace where pods with storage or tenant processes are located. The usecase with nodes located in multiple namespaces is currently unsupported.

YDB Docker container reference

This section provides detailed information about working with YDB when delivered as a Docker container.

The YDB Docker container reference documentation includes the following sections:

- Docker image `ydbplatform/local-ydb` tags naming
- Prerequisites for working with YDB in Docker
- Running YDB in Docker
- Configuring the YDB Docker container
- Custom initialization scripts
- Docker stop

Docker image `ydbplatform/local-ydb` tags naming

For the ydbplatform/local-ydb Docker image, the following naming rules apply for tags:

Tag Name	Description
`latest`	Corresponds to the most recent *stable* version of YDB tested on production clusters. Rebuilt for each new YDB release.
`edge`	A candidate for the next *stable* version, currently undergoing testing. Includes new features but may not be stable and thus unsuitable for production environments.
`trunk`, `main`, `nightly`	The latest version of YDB from the main development branch. Includes all recent changes and is rebuilt nightly. Similarly to `edge`, it is not suitable for production environments.
`XX.Y`	Corresponds to the latest minor version of YDB in a major release `XX.Y`, including all patches.
`XX.Y.ZZ`	Corresponds to the YDB release version `XX.Y.ZZ`.
`XX.Y-slim`, `XX.Y.ZZ-slim`	Compressed binaries of YDB (`ydbd` and `ydb`) with smaller image size but a slower startup. Uses UPX.

Prerequisites for working with YDB in Docker

Before using the YDB in Docker, install and configure the Docker environment. Refer to the official documentation for your operating system:

- Linux
- macOS
- Windows

Alternative installation methods, such as colima, are also supported.

The installation of YDB by downloading the container image happens during the first launch.

Running YDB in Docker

Before start

Create a folder for testing YDB and use it as the current working directory:

```
mkdir ~/ydbd && cd ~/ydbd
mkdir ydb_data
mkdir ydb_certs
```

Launching a container with YDB in Docker

Example of the YDB startup command in Docker with detailed comments:

```
docker_args=(
    -d                              # run container in background and print container ID
    --rm                            # automatically remove the container
    --name ydb-local                # assign a name to the container
    --hostname localhost            # hostname
    --platform linux/amd64          # platform
    -p 2135:2135                    # publish a container grpcs port to the host
    -p 2136:2136                    # publish a container grpc port to the host
    -p 8765:8765                    # publish a container http port to the host
    -p 9092:9092                    # publish a container port to the host that provides Kafka compatibility
    -v $(pwd)/ydb_certs:/ydb_certs  # mount directory with TLS certificates
    -v $(pwd)/ydb_data:/ydb_data    # mount working directory
    -e GRPC_TLS_PORT=2135           # grpcs port, needs to match what's published above
    -e GRPC_PORT=2136               # grpc port, needs to match what's published above
    -e MON_PORT=8765                # http port, needs to match what's published above
    -e YDB_KAFKA_PROXY_PORT=9092    # port, needs to match what's published above
    ydbplatform/local-ydb:latest
)

docker run "${docker_args[@]}"
```

Note

If you are using a Mac with an Apple Silicon processor, emulate the x86_64 CPU instruction set with Rosetta:

- colima with the `colima start --arch aarch64 --vm-type=vz --vz-rosetta` options.
- Docker Desktop with installed and enabled Rosetta 2.

If Rosetta 2 is not enabled, add the `-e YDB_USE_IN_MEMORY_PDISKS=true` parameter to the command for running the Docker container. For more information, see Configuring the YDB Docker container.

For more information about environment variables available when running a Docker container with YDB, see Configuring the YDB Docker container.

With the parameters specified in the example above and running Docker locally, YDB UI YDB will be available at http://localhost:8765.

For more information about stopping and deleting a Docker container with YDB, see Docker stop.

Overriding the configuration file

By default, when starting a Docker container for YDB, a built-in configuration file is used, which provides standard operating parameters. To use your own config, mount it at `/ydb_data/cluster/kikimr_configs/config.yaml`:

```
docker run "${docker_args[@]}" \
  -v $(pwd)/ydb_config/my-ydb-config.yaml:/ydb_data/cluster/kikimr_configs/config.yaml
```

For users who are not experienced with Docker, it's important to understand how to properly mount a configuration file into the container. Below is a step-by-step example:

1. Run the container without specifying a configuration file and without mounting the data directory, so that it generates a default configuration:

   ```
   docker run -d \
     --rm \
     --name ydb-local \
     --hostname localhost \
     --platform linux/amd64 \
     -v $(pwd)/ydb_certs:/ydb_certs \
     -e GRPC_TLS_PORT=2135 \
     -e GRPC_PORT=2136 \
     -e MON_PORT=8765 \
     ydbplatform/local-ydb:latest
   ```

2. Create a directory for your configuration files and copy the generated configuration file from the container directly to it:

   ```
   mkdir ydb_config
   docker cp ydb-local:/ydb_data/cluster/kikimr_configs/config.yaml ydb_config/my-ydb-config.yaml
   ```

3. Stop the container if it's still running, and remove the created data directory:

```
docker stop ydb-local
rm -rf ydb_data
```

4. Edit the copied configuration file `ydb_config/my-ydb-config.yaml` as needed.
5. When running the container, mount the edited configuration file at `/ydb_data/cluster/kikimr_configs/config.yaml`:

```
docker_args=(
    -d
    --rm
    --name ydb-local
    --hostname localhost
    --platform linux/amd64
    -p 2135:2135
    -p 2136:2136
    -p 8765:8765
    -v $(pwd)/ydb_data:/ydb_data
    -v $(pwd)/ydb_certs:/ydb_certs
    -v $(pwd)/ydb_config/my-ydb-config.yaml:/ydb_data/cluster/kikimr_configs/config.yaml
    -e GRPC_TLS_PORT=2135
    -e GRPC_PORT=2136
    -e MON_PORT=8765
    ydbplatform/local-ydb:latest
)

docker run "${docker_args[@]}"
```

In this example, the local file `ydb_config/my-ydb-config.yaml` replaces the default configuration inside the container.

Configuring the YDB Docker container

YDB is configured via environment variables when running in Docker. When starting the YDB Docker container with the `docker run` command, you can specify additional environment variables using the `-e` option to change the container's behavior. For more than one environment variable, specify this option multiple times. Below is the full list of supported environment variables.

Environment variables

Name	Type	Default	Description
`YDB_GRPC_ENABLE_TLS`	`0`, `1`, `false`, or `true`	`true`	Enable the `grpcs://` protocol (gRPC over TLS).
`YDB_GRPC_TLS_DATA_PATH`	`string`	`/ydb_certs`	Directory with TLS certificates for the `grpcs://` connection.
`MON_PORT`	`int`	`8765`	HTTP port of YDB UI
`GRPC_PORT`	`int`	`2136`	gRPC port
`IC_PORT`	`int`	`19001`	Interconnect port
`GRPC_TLS_PORT`	`int`	`2135`	gRPC over TLS port
`YDB_KAFKA_PROXY_PORT`	`int`		Port for connecting using the Kafka API. An empty value disables Kafka API compatibility.
`YDB_ERASURE`	`string`	`none`	Erasure to use, see YDB Cluster Topology
`FQ_CONNECTOR_ENDPOINT`	`string`	`None`	Connection string for the connector to external sources `fq-connector-go`, see Federated query
`YDB_USE_IN_MEMORY_PDISKS`	`0` or `1`	`0`	Makes all data volatile and stored only in RAM. Currently, saving data by disabling this option is supported only on x86_64 processors or virtual machines emulating them.
`YDB_PDISK_SIZE`	`string`	`64GB`	The size of the file for storing data in the `/ydb_data` directory used by the running container. It can be specified as a number in bytes or with a suffix: `KB`, `MB`, or `GB` (for example, `64GB`).
`YDB_DEFAULT_LOG_LEVEL`	`string`	`NOTICE`	Sets the logging level by default. Available values: `CRIT`, `ERROR`, `WARN`, `NOTICE`, `INFO`.
`YDB_ADDITIONAL_LOG_CONFIGS`	`string`	`None`	Sets additional logging levels for specified ydb components in format: `component`:`level`. If you need to enter multiple levels, then enter them separated by commas.
`YDB_FEATURE_FLAGS`	`string`	`None`	Comma-separated list of YDB feature flags
`YDB_ENABLE_COLUMN_TABLES`	`0` or `1`	`0`	Enables column-oriented tables
`YDB_PREINITSCRIPTS_DIR`	`string`	`/preinit.d`	Path to the pre-init scripts directory
`YDB_INITSCRIPTS_DIR`	`string`	`/init.d`	Path to the init scripts directory

Custom initialization scripts

The YDB Docker container supports custom initialization scripts that allow you to automate database setup tasks.

Script directories

There are two directories for placing custom scripts:

Directory	Description	Usage
`/preinit.d`	Scripts in this directory are executed on every container start, **before** the YDB server starts.	Executed on every container start before the server starts. Useful for setting environment variables, configuring logging, or other preparatory tasks that might need to be done each time the container starts.
`/init.d`	Scripts in this directory are executed only **once** after a successful YDB server start. A marker file is created to prevent re-execution on subsequent container restarts.	Executed only once after a successful server start. For example, creating database structure (tables, indexes) and inserting initial data.

Understanding preinit vs init

- **preinit.d**: Executed on every container start, before the YDB server starts. Useful for setting environment variables, configuring logging, or other preparatory tasks that might need to be done each time the container starts.
- **init.d**: Executed only once after a successful YDB server start. Example: creating database structure (tables, indexes) and inserting initial data.

Supported file types

Pre-init scripts (`/preinit.d`)

Extension	Description
`.sh`	Shell scripts. If the script is executable, it is run directly. Otherwise, it is sourced, allowing it to modify environment variables for subsequent scripts.

Init scripts (`/init.d`)

Extension	Description
`.sh`	Shell scripts. If the script is executable, it is run directly. Otherwise, it is sourced.
`.sql`	SQL files. The contents are executed using the YDB command-line interface.
`.sql.gz`	Gzip-compressed SQL files. The contents are decompressed and executed.

Execution order

Scripts are executed in alphabetical order within each directory. Use numeric prefixes to control the execution sequence:

```
/init.d/
├── 01-create-tables.sh
├── 02-create-indexes.sql
└── 03-insert-data.sql.gz
```

Environment variables

You can customize the script directories using environment variables:

Variable	Default	Description
`YDB_PREINITSCRIPTS_DIR`	`/preinit.d`	Path to the pre-init scripts directory
`YDB_INITSCRIPTS_DIR`	`/init.d`	Path to the init scripts directory

Error handling

If any script fails (exits with a non-zero status), the container stops execution and exits with an error. This ensures that initialization errors are immediately visible and prevents the container from running with an incomplete setup.

Examples

Using shell scripts

Create a file `/init.d/01-setup.sh` with the following contents:

```
#!/bin/bash
# /init.d/01-setup.sh
echo "Setting up database..."
/ydb -e grpc://localhost:2136 -d /local --no-discovery sql -s "CREATE TABLE test (id Uint64, PRIMARY KEY (i
d));"
```

Mount the script when starting the container:

```
docker run -d \
    --name ydb-local \
    -v $(pwd)/init.d:/init.d \
    ydbplatform/local-ydb:latest
```

When the container starts, the `test` table will be automatically created using the YDB CLI. The script runs only once after a successful server start.

Using SQL files

Create a file `/init.d/01-create-tables.sql` with the following contents:

```
-- /init.d/01-create-tables.sql
CREATE TABLE users (
    id Uint64,
    name Utf8,
    email Utf8,
    PRIMARY KEY (id)
);

CREATE TABLE orders (
    id Uint64,
    user_id Uint64,
    amount Double,
    PRIMARY KEY (id)
);
```

Mount the init directory:

```
docker run -d \
    --name ydb-local \
    -v $(pwd)/init.d:/init.d \
    ydbplatform/local-ydb:latest
```

When the container starts, two tables — `users` and `orders` — will be automatically created using the SQL script. The script runs only once after a successful server start.

Using pre-init scripts

Create a file `/preinit.d/01-set-env.sh` with the following contents:

```
# /preinit.d/01-set-env.sh
# This script will be sourced, so exported variables will be available
export YDB_DEFAULT_LOG_LEVEL=INFO
```

Mount the pre-init directory:

```
docker run -d \
    --name ydb-local \
    -v $(pwd)/preinit.d:/preinit.d \
    ydbplatform/local-ydb:latest
```

When the container starts, the `YDB_DEFAULT_LOG_LEVEL` environment variable will be exported with the value `INFO`. The script runs on every container start.

Restoring from a backup using init scripts

Create a file `/init.d/01-restore-backup.sh` with the following contents:

```
# /init.d/01-restore-backup.sh
#!/bin/bash
if [ -d "/backup" ] && [ -n "$(ls -A /backup)" ]; then
    /ydb -e grpc://localhost:2136 -d /local --no-discovery tools restore -p . -i /backup
fi
```

Mount the init directory, as well as the volume with your backup:

```
docker run -d \
    --name ydb-local \
    -v $(pwd)/init.d:/init.d \
    -v $(pwd)/backup:/backup \
    ydbplatform/local-ydb:latest
```

When the container starts, restoration from the `/backup` backup will occur in the `/local` database. The script runs only once after a successful server start.

Docker stop

To stop YDB in Docker, run the following command:

```
docker stop ydb-local
```

If the `--rm` flag was specified at startup, the container will be deleted after stopping.

Kill Docker container with YDB

To delete a Docker container with YDB, run the following command:

```
docker kill ydb-local
```

If you want to clean up the file system, delete your work directory using the `rm -rf ~/ydbd` command. This will permanently remove all data inside the local YDB cluster.

Recipes for working with YDB

This section of YDB documentation contains ready-to-use recipes for various aspects of interacting with YDB. They are grouped into the following categories:

- Code recipes using YDB SDK and frameworks
- YDB CLI recipes
- Topic-to-Table Data Transfer Recipes
- Recipes for streaming queries
- YQL recipes

Backup Collection Recipes

Step-by-step guides for common backup collection scenarios.

Getting Started

- Creating Your First Backup Collection - Create a collection, take backups, and monitor operations

Environment Configuration

- Setting Up Backups for Multiple Environments - Configure backups for development and production
- Backup Strategy for Microservices - Organize backups by service boundaries

External Storage

- Exporting Backups to External Storage - Export to S3 or filesystem for disaster recovery
- Importing and Restoring Backups - Restore from external storage

Maintenance

- Backup Maintenance and Cleanup - Manage backup lifecycle and storage
- Validating and Testing Backups - Verify backup integrity

See also

- Backup collections
- Backup and recovery guide
- CREATE BACKUP COLLECTION
- BACKUP
- RESTORE
- DROP BACKUP COLLECTION

Creating Your First Backup Collection

This guide walks you through creating a backup collection, taking your first backups, and monitoring backup operations.

Creating a backup collection

A backup collection is a schema object stored in the database schema. You create and manage collections using SQL statements, and browse them using schema navigation commands (like `ydb scheme ls`) since they appear as directories in the database structure.

Create a collection that includes the tables you want to back up together:

```
-- Create a collection for related tables
CREATE BACKUP COLLECTION production_backups
    ( TABLE orders
    , TABLE products
    , TABLE customers
    )
WITH ( STORAGE = 'cluster', INCREMENTAL_BACKUP_ENABLED = 'true' );
```

Taking backups

After creating the collection, take an initial full backup, then use incremental backups for subsequent operations:

```
-- Take initial full backup
BACKUP production_backups;

-- Make changes to your data...
-- INSERT, UPDATE, or DELETE operations on backed-up tables

-- Later, take incremental backups to capture the changes
BACKUP production_backups INCREMENTAL;
```

> **Note**
>
> Backup operations run asynchronously and are not idempotent — each `BACKUP` command creates a new backup. Before retrying after a timeout, check operation status with `ydb operation list incbackup`.

Monitoring backup operations

Track backup progress and browse your backup structure:

```
# Check backup operation status
ydb operation list incbackup

# Get details for specific operation
ydb operation get <operation-id>

# Browse backup collections
ydb scheme ls .backups/collections/

# List backups in a collection
ydb scheme ls .backups/collections/production_backups/
```

Next steps

- Setting Up Backups for Multiple Environments
- Exporting Backups to External Storage
- Validating and Testing Backups

Setting Up Backups for Multiple Environments

Configure different backup strategies for development and production environments.

Development environment

Use simpler configurations with fewer tables for testing:

```
-- Create collection with fewer tables for testing
CREATE BACKUP COLLECTION dev_test_backups
    ( TABLE users
    , TABLE test_data
    )
WITH ( STORAGE = 'cluster', INCREMENTAL_BACKUP_ENABLED = 'true' );

-- Take daily full backups in development
BACKUP dev_test_backups;
```

Production environment

Create comprehensive collections with more frequent incremental backups:

```
-- Create comprehensive collection for production
CREATE BACKUP COLLECTION prod_daily_backups
    ( TABLE orders
    , TABLE products
    , TABLE customers
    , TABLE inventory
    , TABLE transactions
    )
WITH ( STORAGE = 'cluster', INCREMENTAL_BACKUP_ENABLED = 'true' );

-- Weekly full backup
BACKUP prod_daily_backups;

-- Daily incremental backups
BACKUP prod_daily_backups INCREMENTAL;
```

Recommended backup schedules

Environment	Full Backup	Incremental Backup
Development	Daily	None
Staging	Weekly	Daily
Production	Weekly	Daily or hourly

Next steps

- Backup Strategy for Microservices
- Exporting Backups to External Storage

Backup Strategy for Microservices

Organize backup collections by service boundaries for independent backup and recovery operations.

Service-specific collections

Create separate backup collections for each microservice:

```
-- User service backup collection
CREATE BACKUP COLLECTION user_service_backups
    ( TABLE profiles
    , TABLE preferences
    , TABLE sessions
    )
WITH ( STORAGE = 'cluster', INCREMENTAL_BACKUP_ENABLED = 'true' );

-- Order service backup collection
CREATE BACKUP COLLECTION order_service_backups
    ( TABLE orders
    , TABLE order_items
    , TABLE payments
    )
WITH ( STORAGE = 'cluster', INCREMENTAL_BACKUP_ENABLED = 'true' );

-- Inventory service backup collection
CREATE BACKUP COLLECTION inventory_service_backups
    ( TABLE products
    , TABLE stock_levels
    , TABLE warehouses
    )
WITH ( STORAGE = 'cluster', INCREMENTAL_BACKUP_ENABLED = 'true' );
```

Taking backups independently

Back up each service on its own schedule:

```
-- Take backups for each service independently
BACKUP user_service_backups;
BACKUP order_service_backups;
BACKUP inventory_service_backups;

-- Later, take incremental backups
BACKUP user_service_backups INCREMENTAL;
BACKUP order_service_backups INCREMENTAL;
BACKUP inventory_service_backups INCREMENTAL;
```

Benefits of service-specific collections

- **Independent recovery**: Restore individual services without affecting others
- **Flexible scheduling**: Different backup frequencies per service based on criticality
- **Reduced blast radius**: Issues with one collection don't affect others
- **Team ownership**: Each team can manage their own backup strategy

Next steps

- Exporting Backups to External Storage
- Importing and Restoring Backups

Exporting Backups to External Storage

Export backup collections to S3-compatible storage or filesystem for disaster recovery.

Export to S3

For large backups or disaster recovery, export directly to S3-compatible storage:

```
# Export a backup collection to S3
ydb export s3 \
  --s3-endpoint storage.yandexcloud.net \
  --bucket my-backup-bucket \
  --item src=.backups/collections/production_backups,dst=backups/production_backups

# Export specific backup to S3
ydb export s3 \
  --s3-endpoint storage.yandexcloud.net \
  --bucket my-backup-bucket \
  --item src=.backups/collections/production_backups/20250821141425Z_full,dst=backups/20250821141425Z_full
```

Export to filesystem

For smaller backups or local testing, export to local filesystem:

```
# Export a backup collection
ydb tools dump -p .backups/collections/production_backups -o /backup/exports/production_backups_export

# Export specific backup from a collection
ydb tools dump -p .backups/collections/production_backups/20250601120000Z_full -o /backup/exports/backup_2025
0601
```

Export best practices

- **Export each backup separately**: Export full backups and incrementals individually to maintain chain integrity
- **Preserve chain order**: When exporting a chain, export the full backup first, then incrementals in order
- **Verify exports**: Check that exported data is complete before deleting cluster-stored backups
- **Schedule regular exports**: Automate exports to external storage for disaster recovery

Next steps

- Importing and Restoring Backups
- Backup Maintenance and Cleanup

Importing and Restoring Backups

Import backups from external storage and restore data to your database.

Importing from filesystem

Import previously exported backups:

```
# Import backup to target database
ydb tools restore -p .backups/collections/production_backups_restored -i /backup/exports/production_backups_e
xport

# Import specific backup into a collection
ydb tools restore -p .backups/collections/emergency_restore -i /backup/exports/backup_20250601
```

Importing from S3

```
ydb import s3 \
  --s3-endpoint storage.yandexcloud.net \
  --bucket my-backup-bucket \
  --item src=backups/production_backups,dst=.backups/collections/production_backups
```

Restoring data

After importing backups to the cluster, restore the data:

```
RESTORE production_backups;
```

Disaster recovery workflow

1. **Import full backup**: Import the base full backup first
2. **Import incrementals**: Import each incremental backup in order
3. **Execute RESTORE**: Run the RESTORE command to apply the backup chain

```
# Step 1: Import full backup
ydb tools restore -p .backups/collections/recovery/20250821141425Z_full -i /backup/full_20250821

# Step 2: Import incrementals in order
ydb tools restore -p .backups/collections/recovery/20250822070000Z_incremental -i /backup/inc_20250822

# Step 3: Restore
ydb yql -s "RESTORE recovery;"
```

Next steps

- Backup Maintenance and Cleanup
- Validating and Testing Backups

Backup Maintenance and Cleanup

Manage backup lifecycle and clean up old backups to control storage usage.

Identifying backup chains

Backup directories are named with timestamps and suffixes (`_full` or `_incremental`). Incremental backups belong to the most recent full backup that precedes them chronologically.

```
# List backups sorted by time
ydb scheme ls .backups/collections/production_backups/ | sort
```

Example output:

```
20250601120000Z_full        # Chain 1: full backup
20250601130000Z_incremental # Chain 1: incremental (belongs to 20250601 full)
20250602070000Z_incremental # Chain 1: incremental (belongs to 20250601 full)
20250608120000Z_full        # Chain 2: new full backup starts new chain
20250608130000Z_incremental # Chain 2: incremental (belongs to 20250608 full)
```

When you create a new full backup, it starts a new chain. All incrementals created after that full backup (until the next full) belong to that chain.

Manual cleanup

Remove old backup chains when they are no longer needed:

```
# Remove old backup directories
ydb scheme rmdir -r .backups/collections/production_backups/20250601120000Z_full/

# Always remove complete chains, never partial chains
# Example: Remove old full backup and all its incrementals
ydb scheme rmdir -r .backups/collections/production_backups/20250601120000Z_full/
ydb scheme rmdir -r .backups/collections/production_backups/20250601130000Z_incremental/
ydb scheme rmdir -r .backups/collections/production_backups/20250602070000Z_incremental/
```

> **Warning**
>
> Never delete individual backups from the middle of a chain. Deleting a full backup makes all its incremental backups unrestorable. Always delete complete chains together.

Dropping a collection

Remove an entire backup collection when it's no longer needed:

```
-- Drop a collection when no longer needed (removes collection and all backups)
DROP BACKUP COLLECTION old_collection_name;
```

Safe cleanup workflow

1. Create a new full backup
2. Verify the new backup is complete
3. Export old backup chains to external storage if needed
4. Delete old backup chains (full backup + all its incrementals together)

Storage management tips

- **Monitor storage growth**: Track backup storage usage regularly
- **Set retention policies**: Define how long to keep backup chains
- **Start new chains periodically**: Create new full backups weekly or bi-weekly to limit chain length
- **Export before deleting**: Always export to external storage before removing cluster backups

Next steps

- Validating and Testing Backups
- Exporting Backups to External Storage

Validating and Testing Backups

Verify backup integrity and test restoration procedures.

Verify backup completion

Check that backup operations completed successfully:

```
# List backup operations and check status
ydb operation list incbackup
```

Look for these status values in the output:

Status	Meaning
`SUCCESS`	Operation completed successfully
`PROGRESS`	Operation is still running
`CANCELLED`	Operation was cancelled (currently not applicable — cancel is not yet supported)
`ERROR`	Operation failed

```
# Get detailed information about a specific operation
ydb operation get <operation-id>

# Verify backup directory exists
ydb scheme ls .backups/collections/production_backups/ | tail -1
```

If an operation shows `ERROR` status, check the operation details for the error message and verify that all tables in the collection are accessible.

Verify external exports

Regularly verify that backups can be exported to external storage:

```
# Export to S3 and verify
ydb export s3 \
  --s3-endpoint storage.yandexcloud.net \
  --bucket my-backup-bucket \
  --item src=.backups/collections/production_backups/20250821141425Z_full,dst=backups/test_export

# Check export completed successfully
ydb operation list export/s3

# Verify exported data exists in S3 (using your S3 client)
# aws s3 ls s3://my-backup-bucket/backups/test_export/
```

Test backup restoration

Regularly test that backups can be restored:

```
# Export a recent backup for testing
ydb tools dump -p .backups/collections/production_backups/20250601120000Z_full -o /tmp/test_restore

# Test restore to temporary location (in test environment)
ydb tools restore -p /Root/test_restore_verification -i /tmp/test_restore
```

Validation checklist

- [ ] Backup operations complete without errors
- [ ] Backup directories are created with expected timestamps
- [ ] Exported backups can be imported successfully
- [ ] Restored data matches expected content
- [ ] Incremental chain integrity is maintained

Recommended testing schedule

Test Type	Frequency	Description
Operation status	Daily	Check that scheduled backups complete
Export verification	Weekly	Verify exports to external storage
Full restore test	Monthly	Complete restore to test environment
Disaster recovery drill	Quarterly	Full DR simulation

Setting up monitoring and alerts

YDB does not provide built-in backup monitoring or alerting. Implement external monitoring to detect backup failures:

Example monitoring script

```
#!/bin/bash
# Check for failed backup operations
FAILED=$(ydb operation list incbackup --format json | jq '[.operations[] | select(.status == "ERROR")] | leng
th')

if [ "$FAILED" -gt 0 ]; then
  echo "ALERT: $FAILED backup operation(s) failed" | mail -s "YDB Backup Alert" admin@example.com
fi

# Check that a backup was created in the last 24 hours
LATEST=$(ydb scheme ls .backups/collections/production_backups/ | sort | tail -1)
# Add your own logic to parse timestamp and compare with current time
```

Monitoring recommendations

- Schedule monitoring scripts via cron to run after expected backup times
- Check both operation status (`ERROR`) and that new backups were created
- Integrate with your existing alerting system (email, Slack, PagerDuty, etc.)
- Monitor backup storage growth to avoid running out of space

- Backup Maintenance and Cleanup

Recipes for system tablet backup

Step-by-step guides on enabling system tablet backup and restoring them.

Enabling and restoration

- Enabling and configuring backup — configuring `system_tablet_backup_config` and preparing storage
- Restoring system tablets — switching to Recovery mode and restoring from a local backup

See also

- System tablet backup — concepts and operating principles
- Backup and restoration — overview of backup methods
- system_tablet_backup_config — configuration parameters

Enabling and configuring backup of system tablets

Note

For conceptual information about the mechanism, see the System tablet backup section.

Warning

Only local file systems are supported as backup storage. Network file systems, such as NFS, are not supported and may cause backup corruption or tablet failures.

By default, backup of system tablets is **disabled** because it requires storage configuration. YDB nodes typically do not use a local file system, so enabling it requires an informed decision by the administrator.

To enable it, add the `system_tablet_backup_config` section to the cluster configuration:

```
system_tablet_backup_config:
    filesystem:
        path: "/path/to/backup/directory"
```

The `path` parameter is an absolute path to a directory on the host's local file system for storing backups.

Warning

The backup directory must be writable by the YDB process on each host where system tablets run. Ensure that each host's disk has enough free space to store several backups of all system tablets. For large production environments consisting of dozens of storage nodes, at least 5 GB is recommended.

After changing the configuration, restart the cluster nodes that may run system tablets. Backup will start automatically.

Warning

By default, system tablets can run on any static nodes of the cluster, including those whose disks are part of a static group. Backups are stored locally on the hosts where system tablets run. This means that if static group hosts are lost, the backups that may be needed to restore the static group can also be lost.

It is recommended to configure the `bootstrap_config` section in the cluster configuration so that system tablets run on nodes that are not part of the static group. In this case, backups will be stored separately from the static group data.

Recovering system tablets

Note

For conceptual information about the mechanism, see the System tablet backup section.

Warning

Recovering system tablets is a critical operation that may result in data loss. Perform it only if you have a clear understanding of the problem and after consulting with the operations team. Before starting, make sure you have reviewed all the steps.

Step 1. Put the tablet into Recovery mode

The tablet to be recovered must be put into Recovery mode.

Warning

If recovery is performed after a complete loss of the static group, all system tablets must be put into Recovery mode simultaneously with recreating the static group on new hosts. If you recreate the static group without putting the tablets into Recovery mode, they will automatically start on top of an empty static group, leading to incorrect cluster operation.

1. Determine the ID of the system tablet to be recovered. The tablet ID can be found in the Tablets section of the YDB UI.
2. Save the current cluster configuration to a file `config.yaml`.
   - When using configuration V1, save the static configuration.
   - When using configuration V2, follow the instructions.
3. Determine the list of hosts where the system tablet to be recovered can run based on the cluster configuration. This list will be used in subsequent steps for restarting nodes and updating the configuration.

   For this, it is convenient to use a script that takes the tablet ID and the cluster configuration file as input, which stores the list of nodes where system tablets can run and the mapping from nodes to hosts. The script combines this information and outputs the list of hosts where the given system tablet can run, in a format suitable for pssh.

   Create an isolated environment with PyYAML:

   ```
   python3 -m venv ./recovery && ./recovery/bin/pip install pyyaml
   ```

   Create the script file:

   ```
   cat > find-tablet-hosts.py <<'EOF'
   #!/usr/bin/env python3
   import argparse
   import yaml

   def find_nodes(cfg, tid):
       bootstrap = (cfg.get("bootstrap_config") or {}).get("tablet") or []
       for tablet in bootstrap:
           if str(tablet.get("info", {}).get("tablet_id")) == tid:
               return tablet.get("node") or []

       for tablets_by_type in (cfg.get("system_tablets") or {}).values():
           for tablet in tablets_by_type or []:
               if str(tablet.get("info", {}).get("tablet_id")) == tid:
                   return tablet.get("node") or []

       return []

   parser = argparse.ArgumentParser()
   parser.add_argument("--config-path", required=True, help="Path to cluster configuration file")
   parser.add_argument("--tablet-id", required=True, help="System tablet id")
   args = parser.parse_args()

   with open(args.config_path) as f:
       cfg = yaml.safe_load(f) or {}

   cfg = cfg.get("config", cfg)

   hosts_by_id = {h["node_id"]: h["host"] for h in cfg.get("hosts") or []}

   node_ids = find_nodes(cfg, args.tablet_id)
   if not node_ids:
       node_ids = list(hosts_by_id)

   for node_id in sorted(set(node_ids)):
       host = hosts_by_id.get(node_id)
       if host is not None:
           print(host)
   EOF
   ```

   Run the script, substituting the path to your configuration and the tablet ID:

   Example:

```
./recovery/bin/python find-tablet-hosts.py --config-path config.yaml --tablet-id <tablet-id> > hosts.txt
```

4. Modify the saved configuration by adding `boot_type: RECOVERY` to the startup configuration section of the tablet being recovered and reduce the list of nodes where the tablet being recovered can run (the `node` array) to a single node. Example for tablet `Hive` with ID `72057594037968897`:
   - When using `bootstrap_config`:

     ```
     bootstrap_config:
         tablet:
         - type: FLAT_HIVE
             node:
             - 1
             info:
                 tablet_id: '72057594037968897'
                 channels:
                 - channel: 0
                 history:
                 - from_generation: 0
                     group_id: 0
                 channel_erasure_name: mirror-3-dc
                 - channel: 1
                 history:
                 - from_generation: 0
                     group_id: 0
                 channel_erasure_name: mirror-3-dc
                 - channel: 2
                 history:
                 - from_generation: 0
                     group_id: 0
                 channel_erasure_name: mirror-3-dc
             boot_type: RECOVERY
     ```

   - When using `system_tablets`:

     ```
     flat_hive:
     - info:
         tablet_id: 72057594037968897
       node:
       - 9
       boot_type: RECOVERY
     ```

5. Update the configuration in the cluster.
   - When using configuration V1, update the static configuration on all hosts obtained in step 3 using the command:

     Copy the updated configuration to a temporary file on each host:

     ```
     pscp -h hosts.txt config.yaml /tmp/config.yaml.new
     ```

     Make a backup of the current configuration, replace it with the new version, and protect it from accidental changes:

     ```
     pssh -h hosts.txt 'sudo cp /opt/ydb/cfg/config.yaml /opt/ydb/cfg/config.yaml.bak && sudo mv /tmp/con
     fig.yaml.new /opt/ydb/cfg/config.yaml && sudo chattr +i /opt/ydb/cfg/config.yaml'
     ```

   - When using configuration V2, follow the instructions.
6. Restart all nodes where the tablet being recovered can run. If any node is unavailable and cannot be restarted, isolate it from the cluster over the network — for example, using a firewall.

   Example:

   ```
   pssh -h hosts.txt 'sudo systemctl restart ydbd-storage; sleep 10'
   ```

   > **Warning**
   >
   > Make sure that all nodes where the tablet being recovered can run are restarted with the updated configuration or isolated from the cluster over the network before starting recovery. During recovery, old data is erased and replaced with data from the backup. If at that moment the tablet starts in normal mode on a node with the old configuration, it may start working with partially recovered data.

7. Make sure that:
   - There are no issues with the tablet in HealthCheck.
   - The tablet is not restarting.
   - The recovery form is available in the tablet's App in the YDB UI.

Step 2. Find the backup files

1. On each host obtained in step 3, check for the presence of backups. The path to backups is determined by the `path` parameter in the `system_tablet_backup_config` configuration section.

   The name of each backup contains key information: `backup_<timestamp>_g<generation>_s<step>`, where:

   - `timestamp` — backup creation time;
   - `generation` — tablet generation, increases with each tablet restart;

- `step` — tablet step within a generation, increases with each change in tablet state.

2. Select the most recent backup suitable for recovery.

   Select the backup with the **maximum generation**, and if generations are equal, with the **maximum step**.

   Make sure the backup is fully written. The selected backup must contain the `snapshot` directory, **not** `snapshot.tmp`. The presence of `snapshot.tmp` means that the snapshot write was not completed and the backup is not suitable for recovery. In this case, select the previous most recent backup.

   ```
   ls /path/to/backup/directory/hive/72057594037968897/backup_20251007T193502_g214_s1222/snapshot/
   ```

   ```
   manifest.json
   schema.json
   Tablet.json
   TabletFollowerGroup.json
   ...
   ```

   Check that the backup files contain data:

   ```
   ls -lh /path/to/backup/directory/hive/72057594037968897/backup_20251007T193502_g214_s1222/snapshot
   ```

   ```
   total 128K
   -rw-r--r-- 1 ydb disk  591 May 27 11:34 manifest.json
   -rw-r--r-- 1 ydb disk  12K May 27 11:34 schema.json
   -rw-r--r-- 1 ydb disk  47K May 27 11:34 Tablet.json
   -rw-r--r-- 1 ydb disk  41K May 27 11:34 TabletFollowerGroup.json
   ...
   ```

   Calculate the checksum of the `changelog.json` file and verify it against the checksum recorded in `changelog.json.sha256`:

   ```
   sha256sum /path/to/backup/directory/hive/72057594037968897/backup_20251007T193502_g214_s1222/changelog.j
   son
   ```

   ```
   ea4bdc2f7afaf7b6d35adbf13b5360e4e4a19046f742effdf1b4f0bb9c449185
   ```

   ```
   cat /path/to/backup/directory/hive/72057594037968897/backup_20251007T193502_g214_s1222/changelog.json.sh
   a256
   ```

   ```
   ea4bdc2f7afaf7b6d35adbf13b5360e4e4a19046f742effdf1b4f0bb9c449185
   ```

   If the checksums differ, two situations are possible:

   - The last entry in `changelog.json` was not fully written. In this case, the checksum stored in `changelog.json.sha256` is found in one of the entries in `changelog.json` in the `prev_sha256` field. To recover, you need to edit the files: remove/complete the incompletely written entries in `changelog.json` and update the checksum in `changelog.json.sha256`.
   - Data corruption has occurred, recovery is impossible.

Step 3. Transfer the backup files

1. Determine which host the tablet is running on in Recovery mode. To do this, open the YDB UI and find the host where the tablet is running.
2. If the backup files are on a different host, copy them to the host with the tablet in Recovery mode using `scp`, `rsync`, or any other available tool:

   Copy the backup from the backup directory to your home directory:

   ```
   cp -R /path/to/backup/directory/hive/72057594037968897/backup_20251007T193502_g214_s1222 ~/backup_202510
   07T193502_g214_s1222
   ```

   Copy the backup to the target host:

   ```
   scp -r ~/backup_20251007T193502_g214_s1222 target-host:~/backup_20251007T193502_g214_s1222
   ```

   If direct copying between hosts is not available, copy through an intermediate host:

   ```
   scp -r backup-host:~/backup_20251007T193502_g214_s1222 backup_20251007T193502_g214_s1222

   scp -r backup_20251007T193502_g214_s1222 target-host:~/backup_20251007T193502_g214_s1222
   ```

   After copying the backup to the target host, grant access to it for the ydb process:

   ```
   chown -R ydb ~/backup_20260527104029Z_g1911_s
   ```

Step 4. Perform the recovery

1. Open the App of the tablet being restored in the YDB UI.
2. In the recovery form, specify the full path to the directory with the backup files, for example:

```
/path/to/backup/directory/hive/72057594037968897/backup_20251007T193502_g214_s1222
```

3. If necessary, set the flags:
   - **Dry Run** — performs a trial recovery without making changes to the storage. Allows you to verify the correctness of the backup. After the trial recovery completes, you must restart the tablet.
   - **Skip Checksum Validation** — skips the checksum verification of the backup files.

   Warning

   Always perform a Dry Run before recovery to verify the correctness of the backup.

   Warning

   Skip checksum verification only if you have manually edited the backup files. In other cases, it is recommended to keep verification enabled to ensure the integrity of the restored data.

4. Click the **Start Restore** button. Before starting the recovery, the system will ask for confirmation, as the operation overwrites the existing tablet data. Confirm the action to start. After the recovery starts, the form becomes unavailable — a restart is not possible until the tablet is restarted.

   Note

   You can also start the recovery using `curl` by sending a POST request to the tablet's App page with the `restoreBackup` parameter:

   ```
   curl -X POST "http://<host>:<mon_port>/tablets/app?TabletID=72057594037968897&restoreBackup=/tablet/hive/72057594037968897/backup_20251007T193502_g214_s1222"
   ```

   Where `<host>` is the cluster node address, `<mon_port>` is the monitoring port of this node.

5. Monitor the recovery progress. The page **does not update automatically** — to get the current status, refresh the page manually. The recovery duration depends on the backup size.

   Note

   The recovery is performed server-side and does not depend on the browser. You can close the page or browser — this **will not interrupt** the recovery process. When you reopen the page, the current status will be displayed.

   The current operation status is displayed below the form. Possible statuses:

   - `Restoring from '<path>'` — recovery is in progress, data from the backup is being read and written to the storage. Additionally, a **progress bar** with the operation completion percentage is displayed.
   - `Restore from '<path>' completed successfully` — recovery completed successfully. You can proceed to the next step.
   - `Restore from '<path>' completed, but changelog is not fully restored` — the main tablet data has been restored, but the tail of the change log in the backup is damaged, and some recent changes are lost. Examine which data was lost and, if necessary, restore it manually, or proceed to the next step.
   - `Restore from '<path>' failed: <error description>` — recovery completed with an error. Examine the error description and retry if necessary.

   To forcibly interrupt the recovery, **restart the tablet**.
6. Wait for the recovery to complete successfully. If the recovery form becomes available again (the **Start Restore** button is active, the status is reset), this means the tablet was restarted and the recovery was interrupted. In this case, start the recovery again from step 2.

Step 5. Return the tablet to normal operation mode

After successful recovery:

1. Restore the configuration to its original state by removing `boot_type: RECOVERY` from the startup configuration section of the tablet being recovered and restoring the original list of nodes where the tablet being recovered can run.
   - When using configuration V1, update the static configuration on all hosts obtained in step 3 using the command:

     Remove the protection against accidental changes and replace the new configuration with the original version:

     ```
     pssh -h hosts.txt 'sudo chattr -i /opt/ydb/cfg/config.yaml && sudo mv /opt/ydb/cfg/config.yaml.bak /opt/ydb/cfg/config.yaml'
     ```

   - When using configuration V2, follow the instructions.
2. Restart all nodes where the tablet being recovered can run. If any nodes were isolated from the cluster over the network in previous steps, remove the network isolation.

   Example:

```
pssh -h hosts.txt 'sudo systemctl restart ydbd-storage; sleep 10'
```

3. Make sure that:
   - There are no issues with the tablet in HealthCheck.
   - The tablet does not restart.
   - The recovery form is absent in the tablet's App in YDB UI.
4. Restart all cluster nodes one by one to synchronize the state of internal in-memory caches with the tablet state. After restarting each node, wait for it to return to a healthy state and make sure there are no issues in HealthCheck; only then proceed to the next node.

Code recipes using YDB SDK and frameworks

This section contains code recipes in different programming languages for solving various common practical tasks using the YDB SDK.

Contents:

- Driver initialization
- Authentication
  - Using a token
  - Anonymous
  - Service account file
  - Metadata service
  - Using environment variables
  - Using login and password
- Load balancing
  - Uniform random selection
  - Prefer nearest datacenter
  - Prefer availability zone
- Retry query execution
- Set session pool size
- Data insert
- Batch data insert
- Setting transaction execution mode
- Configuring table TTL (Time to Live)
- Vector search
- Coordination
  - Distributed lock
  - Service discovery
  - Configuration publishing
  - Leader election
- Problem diagnostics
  - Enable logging
  - Connect metrics to Prometheus
  - Tracing with OpenTelemetry

See also:

- YDB for Application Developers / Software Engineers
- Example applications working with YDB
- Reference for YDB SDK

Initialize the driver

To connect to YDB, you must specify the required parameters (see Connecting to a YDB server) and optional parameters that control driver behavior.

Below are examples of connecting to YDB (creating a driver) in different YDB SDKs.

Go

Native SDK

```
package main

import (
  "context"

  "github.com/ydb-platform/ydb-go-sdk/v3"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()

  db, err := ydb.Open(ctx, "grpc://localhost:2136/local")
  if err != nil {
      panic(err)
  }
  defer db.Close()

  // ...
}
```

database/sql

Using a connector (recommended)

```
package main

import (
  "context"
  "database/sql"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()

  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)

  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }
  defer connector.Close()

  db := sql.OpenDB(connector)
  defer db.Close()

  // ...
}
```

Using a connection string

The `database/sql` driver is registered when you import the driver package with a blank import:

```go
package main

import (
  "database/sql"

  _ "github.com/ydb-platform/ydb-go-sdk/v3"
)

func main() {
  db, err := sql.Open("ydb", "grpc://localhost:2136/local")
  if err != nil {
    panic(err)
  }
  defer db.Close()

  // ...
}
```

Java

Native SDK

```java
public void work() {
    try (GrpcTransport transport = GrpcTransport.forConnectionString("grpc://localhost:2136/local")
            .build()) {
        // Work with transport
        doWork(transport);
    }
}
```

JDBC

```java
public void work() throws SQLException {
    // tech.ydb.jdbc.YdbDriver must be on the classpath for DriverManager auto-loading
    try (Connection connection = DriverManager.getConnection("jdbc:ydb:grpc://localhost:2136/local")) {
        // Work with connection
        doWork(connection);
    }
}
```

For Spring Boot, set the URL and driver class in `application.properties` or `application.yml` (`spring.datasource.url`, `spring.datasource.driver-class-name`).

Spring Boot, ORMs, and other JDBC stacks (Hibernate, JOOQ, MyBatis, and so on) talk to YDB like any JDBC source: add the YDB JDBC dependency and configure the URL — you do not need to configure native `GrpcTransport` separately.

Python

Native SDK

```python
import ydb

with ydb.Driver(connection_string="grpc://localhost:2136?database=/local") as driver:
  driver.wait(timeout=5)
  ...
```

Native SDK (Asyncio)

```python
import ydb
import asyncio

async def ydb_init():
  async with ydb.aio.Driver(endpoint="grpc://localhost:2136", database="/local") as driver:
    await driver.wait()
    ...

asyncio.run(ydb_init())
```

C# (.NET)

```csharp
using Ydb.Sdk;

var config = new DriverConfig(
    endpoint: "grpc://localhost:2136",
    database: "/local"
);

await using var driver = await Driver.CreateInitialized(config);
```

JavaScript

```
import { Driver } from '@ydbjs/core'

const driver = new Driver('grpc://localhost:2136/local')
await driver.ready()
```

PHP

```
<?php

use YdbPlatform\Ydb\Ydb;

$config = [
    // Database path
    'database'    => '/ru-central1/b1glxxxxxxxxxxxxxxx/etn0xxxxxxxxxxxxxxx',

    // Database endpoint
    'endpoint'    => 'ydb.serverless.yandexcloud.net:2135',

    // Auto discovery (dedicated server only)
    'discovery'   => false,

    // IAM config
    'iam_config'  => [
        // 'root_cert_file' => './CA.pem', // Root CA file (uncomment for dedicated server)
    ],

    'credentials' => new \YdbPlatform\Ydb\Auth\Implement\AccessTokenAuthentication('AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA') // use from reference/ydb-sdk/auth
];

$ydb = new Ydb($config);
```

Rust

```
use ydb::{AccessTokenCredentials, ClientBuilder, YdbResult};

#[tokio::main]
async fn main() -> YdbResult<()> {
    let client = ClientBuilder::new_from_connection_string("grpc://localhost:2136/local")?
        .with_credentials(AccessTokenCredentials::from("..."))
        .client()?;
    client.wait().await?;
    Ok(())
}
```

Authentication

YDB supports multiple authentication methods when connecting to the server side. Each of them is usually specific to a particular pair of environments, that is, depends on where you run your client application (in the trusted YDB zone or outside it) and the YDB server part (in a Docker container, Yandex.Cloud, data cloud, or an independent cluster).

This section contains code recipes with authentication settings in different YDB SDKs. For a general description of the SDK authentication principles, see the Authentication in an SDK.

Table of contents:

- Using a token
- Anonymous
- Service account file
- Metadata service
- Using environment variables
- Username and password based

Authentication using a token

Below are examples of authentication with a token in different YDB SDKs.

Go

Native SDK

```
package main

import (
  "context"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithAccessTokenCredentials(os.Getenv("YDB_TOKEN")),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  ...
}
```

database/sql

If you use a connector to create a connection to YDB

```
package main

import (
  "context"
  "database/sql"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithAccessTokenCredentials(os.Getenv("YDB_TOKEN")),
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)
  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }
  db := sql.OpenDB(connector)
  defer db.Close()
  ...
}
```

If you use a connection string

```
package main

import (
  "context"
  "database/sql"
  "os"

  _ "github.com/ydb-platform/ydb-go-sdk/v3"
)

func main() {
  db, err := sql.Open("ydb", "grpcs://localhost:2135/local?token="+os.Getenv("YDB_TOKEN"))
  if err != nil {
    panic(err)
  }
  defer db.Close()
  ...
}
```

Java

Native SDK

```
public void work(String accessToken) {
    AuthProvider authProvider = new TokenAuthProvider(accessToken);

    try (GrpcTransport transport = GrpcTransport.forConnectionString("grpcs://localhost:2135/local")
            .withAuthProvider(authProvider)
            .build();
         QueryClient queryClient = QueryClient.newClient(transport).build()) {

        doWork(queryClient);
    }
}
```

JDBC

```
public void work() throws SQLException {
    // Connection with an explicit authentication token value
    Properties props1 = new Properties();
    props1.setProperty("token", "AQAD-XXXXXXXXXXXXXXXXXXX");
    try (Connection connection = DriverManager.getConnection("jdbc:ydb:grpc://localhost:2136/local", props1))
{
        doWork(connection);
    }

    // Connection with the token read from the specified file
    Properties props2 = new Properties();
    props2.setProperty("tokenFile", "~/.ydb_token");
    try (Connection connection = DriverManager.getConnection("jdbc:ydb:grpc://localhost:2136/local", props2))
{
        doWork(connection);
    }
}
```

In Spring Boot, ORMs, and other JDBC wrappers, use the same JDBC URL and authentication parameters as above (for example `spring.datasource.url` with query parameters or `spring.datasource.*` for the token and token file).

JavaScript

```
import { Driver } from "@ydbjs/core";
import { AccessTokenCredentialsProvider } from "@ydbjs/auth/access-token";

const driver = new Driver("grpc://localhost:2136/local", {
  credentialsProvider: new AccessTokenCredentialsProvider({
    token: "accessToken",
  }),
});

await driver.ready();
```

Python

Native SDK

```
import os
import ydb

with ydb.Driver(
    connection_string=os.environ["YDB_CONNECTION_STRING"],
    credentials=ydb.credentials.AccessTokenCredentials(os.environ["YDB_TOKEN"]),
) as driver:
    driver.wait(timeout=5)
    ...
```

Native SDK (Asyncio)

```
import os
import ydb
import asyncio

async def ydb_init():
    async with ydb.aio.Driver(
        endpoint=os.environ["YDB_ENDPOINT"],
        database=os.environ["YDB_DATABASE"],
        credentials=ydb.credentials.AccessTokenCredentials(os.environ["YDB_TOKEN"]),
    ) as driver:
        await driver.wait()
        ...

asyncio.run(ydb_init())
```

SQLAlchemy

```
import os
import sqlalchemy as sa

engine = sa.create_engine(
    "yql+ydb://localhost:2136/local",
    connect_args={
        "credentials": {"token": os.environ["YDB_TOKEN"]}
    }
)
with engine.connect() as connection:
    result = connection.execute(sa.text("SELECT 1"))
```

C# (.NET)

```
using Ydb.Sdk;
using Ydb.Sdk.Auth;

const string endpoint = "grpc://localhost:2136";
const string database = "/local";
const string token = "MY_VERY_SECURE_TOKEN";

var config = new DriverConfig(
    endpoint: endpoint,
    database: database,
    credentials: new TokenProvider(token)
);

await using var driver = await Driver.CreateInitialized(config);
```

PHP

```
<?php

use YdbPlatform\Ydb\Ydb;
use YdbPlatform\Ydb\Auth\Implement\AccessTokenAuthentication;

$config = [

    // Database path
    'database'    => '/local',

    // Database endpoint
    'endpoint'    => 'localhost:2136',

    // Auto discovery (dedicated server only)
    'discovery'   => false,

    // IAM config
    'iam_config'  => [
        'insecure' => true,
        // 'root_cert_file' => './CA.pem', // Root CA file (uncomment for dedicated server)
    ],

    'credentials' => new AccessTokenAuthentication('AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA')
];

$ydb = new Ydb($config);
```

Anonymous authentication

Below are examples of anonymous authentication in different YDB SDKs.

Go

Native SDK

Anonymous authentication is the default.
You can enable it explicitly as follows:

```
package main

import (
  "context"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithAnonymousCredentials(),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  ...
}
```

database/sql

Anonymous authentication is the default.
You can enable it explicitly as follows:

```
package main

import (
  "context"
  "database/sql"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithAnonymousCredentials(),
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)
  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }
  db := sql.OpenDB(connector)
  defer db.Close()
  ...
}
```

Java

Native SDK

```
public void work(String connectionString) {
    AuthProvider authProvider = NopAuthProvider.INSTANCE;

    try (GrpcTransport transport = GrpcTransport.forConnectionString(connectionString)
            .withAuthProvider(authProvider)
            .build();
         QueryClient queryClient = QueryClient.newClient(transport).build()) {

        doWork(queryClient);
    }
}
```

JDBC

```
public void work() throws SQLException {
    // Connection with no extra options — anonymous authentication
    try (Connection connection = DriverManager.getConnection("jdbc:ydb:grpc://localhost:2136/local")) {
        doWork(connection);
    }
}
```

In Spring Boot, ORMs, and other JDBC wrappers, use the same JDBC URL as above (for example `spring.datasource.url`).

JavaScript

```
import { Driver } from "@ydbjs/core";
import { AnonymousCredentialsProvider } from "@ydbjs/auth/anonymous";

const driver = new Driver("grpc://localhost:2136/local", {
  credentialsProvider: new AnonymousCredentialsProvider(),
});

await driver.ready();
```

Python

Native SDK

```
import os
import ydb

with ydb.Driver(
    connection_string=os.environ["YDB_CONNECTION_STRING"],
    credentials=ydb.credentials.AnonymousCredentials(),
) as driver:
    driver.wait(timeout=5)
    ...
```

Native SDK (Asyncio)

```
import os
import ydb
import asyncio

async def ydb_init():
    async with ydb.aio.Driver(
        endpoint=os.environ["YDB_ENDPOINT"],
        database=os.environ["YDB_DATABASE"],
        credentials=ydb.credentials.AnonymousCredentials(),
    ) as driver:
        await driver.wait()
        ...

asyncio.run(ydb_init())
```

SQLAlchemy

```
import sqlalchemy as sa

engine = sa.create_engine("yql+ydb://localhost:2136/local")
with engine.connect() as connection:
    result = connection.execute(sa.text("SELECT 1"))
```

C# (.NET)

```
using Ydb.Sdk;
using Ydb.Sdk.Auth;

const string endpoint = "grpc://localhost:2136";
const string database = "/local";

var config = new DriverConfig(
    endpoint: endpoint,
    database: database,
    credentials: new AnonymousProvider()
);

await using var driver = await Driver.CreateInitialized(config);
```

PHP

```php
<?php

use YdbPlatform\Ydb\Ydb;
use YdbPlatform\Ydb\Auth\Implement\AnonymousAuthentication;

$config = [

    // Database path
    'database'    => '/local',

    // Database endpoint
    'endpoint'    => 'localhost:2136',

    // Auto discovery (dedicated server only)
    'discovery'   => false,

    // IAM config
    'iam_config'  => [
        'insecure' => true,
        // 'root_cert_file' => './CA.pem', // Root CA file (uncomment for dedicated server)
    ],

    'credentials' => new AnonymousAuthentication()
];

$ydb = new Ydb($config);
```

Authentication using a service account file

Below are examples of authentication with a service account file in different YDB SDKs.

Go

Native SDK

```
package main

import (
  "context"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  yc "github.com/ydb-platform/ydb-go-yc"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    yc.WithServiceAccountKeyFileCredentials(
      os.Getenv("YDB_SERVICE_ACCOUNT_KEY_FILE_CREDENTIALS"),
    ),
    yc.WithInternalCA(), // append Yandex Cloud certificates
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  ...
}
```

database/sql

```
package main

import (
  "context"
  "database/sql"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  yc "github.com/ydb-platform/ydb-go-yc"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    yc.WithServiceAccountKeyFileCredentials(
      os.Getenv("YDB_SERVICE_ACCOUNT_KEY_FILE_CREDENTIALS"),
    ),
    yc.WithInternalCA(), // append Yandex Cloud certificates
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)
  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }
  db := sql.OpenDB(connector)
  defer db.Close()
  ...
}
```

Java

Native SDK

```
public void work(String connectionString, String saKeyPath) {
    AuthProvider authProvider = CloudAuthHelper.getServiceAccountFileAuthProvider(saKeyPath);

    try (GrpcTransport transport = GrpcTransport.forConnectionString(connectionString)
            .withAuthProvider(authProvider)
            .build();
         QueryClient queryClient = QueryClient.newClient(transport).build()) {

        doWork(queryClient);
    }
}
```

JDBC

```
public void work() throws SQLException {
    Properties props = new Properties();
    props.setProperty("saKeyFile", "~/keys/sa_key.json");
    try (Connection connection = DriverManager.getConnection("jdbc:ydb:grpc://localhost:2136/local", props))
{
        doWork(connection);
    }

    // You can also set saKeyFile in the JDBC URL
    try (Connection connection = DriverManager.getConnection("jdbc:ydb:grpc://localhost:2136/local?saKeyFile=
~/keys/sa_key.json")) {
        doWork(connection);
    }
}
```

In Spring Boot, ORMs, and other JDBC wrappers, use the same JDBC URL and `saKeyFile` (in the URL or in `DataSource` properties) as above.

JavaScript

Loading service account data from a file:

```
import { Driver } from "@ydbjs/core";
import { ServiceAccountCredentialsProvider } from "@ydbjs/auth-yandex-cloud";

const driver = new Driver("grpc://localhost:2136/local", {
  credentialsProvider: ServiceAccountCredentialsProvider.fromFile("./authorized_key.json"),
});

await driver.ready();
```

Loading service account data from a third-party source (for example, a secrets store):

```
import { Driver } from "@ydbjs/core";
import { ServiceAccountCredentialsProvider } from "@ydbjs/auth-yandex-cloud";

const driver = new Driver("grpc://localhost:2136/local", {
  credentialsProvider: new ServiceAccountCredentialsProvider({
    id: "serviceAccountId",
    keyId: "accessKeyId",
    privateKey: "-----BEGIN PRIVATE KEY-----\n...",
  }),
});

await driver.ready();
```

Python

Native SDK

```
import os
import ydb
import ydb.iam

with ydb.Driver(
    connection_string=os.environ["YDB_CONNECTION_STRING"],
    # service account key should be in the local file,
    # and SA_KEY_FILE environment variable should point to it
    credentials=ydb.iam.ServiceAccountCredentials.from_file(os.environ["SA_KEY_FILE"]),
) as driver:
    driver.wait(timeout=5)
    ...
```

Native SDK (Asyncio)

```
import os
import asyncio
import ydb
import ydb.iam

async def ydb_init():
    async with ydb.aio.Driver(
        endpoint=os.environ["YDB_ENDPOINT"],
        database=os.environ["YDB_DATABASE"],
        # service account key should be in the local file,
        # and SA_KEY_FILE environment variable should point to it
        credentials=ydb.iam.ServiceAccountCredentials.from_file(os.environ["SA_KEY_FILE"]),
    ) as driver:
        await driver.wait()
        ...

asyncio.run(ydb_init())
```

SQLAlchemy

```
import os
import sqlalchemy as sa
import ydb.iam

engine = sa.create_engine(
    "yql+ydb://localhost:2136/local",
    connect_args={
        "credentials": ydb.iam.ServiceAccountCredentials.from_file(
            os.environ["YDB_SERVICE_ACCOUNT_KEY_FILE_CREDENTIALS"]
        )
    }
)
with engine.connect() as connection:
    result = connection.execute(sa.text("SELECT 1"))
```

C# (.NET)

```
using Ydb.Sdk;
using Ydb.Sdk.Yc;

const string endpoint = "grpc://localhost:2136";
const string database = "/local";

var saProvider = new ServiceAccountProvider(
    saFilePath: "path/to/sa_file.json" // Path to file with service account JSON info);
);
await saProvider.Initialize();

var config = new DriverConfig(
    endpoint: endpoint,
    database: database,
    credentials: saProvider
);

await using var driver = await Driver.CreateInitialized(config);
```

PHP

```
<?php

use YdbPlatform\Ydb\Ydb;
use YdbPlatform\Ydb\Auth\JwtWithJsonAuthentication;

$config = [
    'database'    => '/ru-central1/b1glxxxxxxxxxxxxxxx/etn0xxxxxxxxxxxxxxx',
    'endpoint'    => 'ydb.serverless.yandexcloud.net:2135',
    'discovery'   => false,
    'iam_config'  => [
        'temp_dir'       => './tmp', // Temp directory
        // 'root_cert_file' => './CA.pem', // Root CA file (uncomment for dedicated server)ы
    ],

    'credentials' => new JwtWithJsonAuthentication('./jwtjson.json')
];

$ydb = new Ydb($config);
```

or

```
<?php

use YdbPlatform\Ydb\Ydb;
use YdbPlatform\Ydb\Auth\JwtWithPrivateKeyAuthentication;

$config = [
    'database'    => '/ru-central1/b1glxxxxxxxxxxxxxxx/etn0xxxxxxxxxxxxxxx',
    'endpoint'    => 'ydb.serverless.yandexcloud.net:2135',
    'discovery'   => false,
    'iam_config'  => [
        'temp_dir'           => './tmp', // Temp directory
        // 'root_cert_file' => './CA.pem', // Root CA file (uncomment for dedicated server)

    ],

    'credentials' => new JwtWithPrivateKeyAuthentication(
        "ajexxxxxxxxx","ajeyyyyyyyyy",'./private.key')

];

$ydb = new Ydb($config);
```

Authentication using the metadata service

Below are examples of authentication with the metadata service in different YDB SDKs.

Go

Native SDK

```
package main

import (
  "context"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  yc "github.com/ydb-platform/ydb-go-yc-metadata"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    yc.WithCredentials(),
    yc.WithInternalCA(), // append Yandex Cloud certificates
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  ...
}
```

database/sql

```
package main

import (
  "context"
  "database/sql"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  yc "github.com/ydb-platform/ydb-go-yc-metadata"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    yc.WithCredentials(),
    yc.WithInternalCA(), // append Yandex Cloud certificates
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)
  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }
  db := sql.OpenDB(connector)
  defer db.Close()
  ...
}
```

Java

Native SDK

```
public void work(String connectionString) {
    AuthProvider authProvider = CloudAuthHelper.getMetadataAuthProvider();

    try (GrpcTransport transport = GrpcTransport.forConnectionString(connectionString)
            .withAuthProvider(authProvider)
            .build();
         QueryClient queryClient = QueryClient.newClient(transport).build()) {

        doWork(queryClient);
    }
}
```

JDBC

```
public void work() throws SQLException {
    Properties props = new Properties();
    props.setProperty("useMetadata", "true");
    try (Connection connection = DriverManager.getConnection("jdbc:ydb:grpc://localhost:2136/local", props))
{
        doWork(connection);
    }

    // You can also set useMetadata in the JDBC URL
    try (Connection connection = DriverManager.getConnection("jdbc:ydb:grpc://localhost:2136/local?useMetadat
a=true")) {
        doWork(connection);
    }
}
```

In Spring Boot, ORMs, and other JDBC wrappers, pass the same JDBC URLs and parameters (`useMetadata` in the URL or in the data source properties) as in the example above.

JavaScript

```
import { Driver } from "@ydbjs/core";
import { MetadataCredentialsProvider } from "@ydbjs/auth/metadata";

const driver = new Driver("grpc://localhost:2136/local", {
  credentialsProvider: new MetadataCredentialsProvider(),
});

await driver.ready();
```

Python

Native SDK

```
import os
import ydb
import ydb.iam

with ydb.Driver(
    connection_string=os.environ["YDB_CONNECTION_STRING"],
    credentials=ydb.iam.MetadataUrlCredentials(),
) as driver:
    driver.wait(timeout=5)
    ...
```

Native SDK (Asyncio)

```
import os
import ydb
import ydb.iam
import asyncio

async def ydb_init():
    async with ydb.aio.Driver(
        endpoint=os.environ["YDB_ENDPOINT"],
        database=os.environ["YDB_DATABASE"],
        credentials=ydb.iam.MetadataUrlCredentials(),
    ) as driver:
        await driver.wait()
        ...

asyncio.run(ydb_init())
```

SQLAlchemy

```
import sqlalchemy as sa
import ydb.iam

engine = sa.create_engine(
    "yql+ydb://localhost:2136/local",
    connect_args={
        "credentials": ydb.iam.MetadataUrlCredentials()
    }
)
with engine.connect() as connection:
    result = connection.execute(sa.text("SELECT 1"))
```

C# (.NET)

```
using Ydb.Sdk;
using Ydb.Sdk.Yc;

var metadataProvider = new MetadataProvider();

// Await initial IAM token.
await metadataProvider.Initialize();

var config = new DriverConfig(
    endpoint: endpoint, // Database endpoint, "grpcs://host:port"
    database: database, // Full database path
    credentials: metadataProvider
);

await using var driver = await Driver.CreateInitialized(config);
```

PHP

```
<?php

use YdbPlatform\Ydb\Ydb;
use YdbPlatform\Ydb\Auth\Implement\MetadataAuthentication;

$config = [

    // Database path
    'database'    => '/local',

    // Database endpoint
    'endpoint'    => 'localhost:2136',

    // Auto discovery (dedicated server only)
    'discovery'   => false,

    // IAM config
    'iam_config'  => [
        'insecure' => true,
        // 'root_cert_file' => './CA.pem', // Root CA file (uncomment for dedicated server)
    ],

    'credentials' => new MetadataAuthentication()
];

$ydb = new Ydb($config);
```

Authentication using environment variables

When using this method, the authentication mode and its parameters are defined by the environment that an application is run in, as described here.

By setting one of the following environment variables, you can control the authentication method:

- `YDB_SERVICE_ACCOUNT_KEY_FILE_CREDENTIALS=<path/to/sa_key_file>` — use a service account key file in Yandex Cloud.
- `YDB_ANONYMOUS_CREDENTIALS="1"` — use anonymous authentication. Useful for testing against a Docker container with YDB.
- `YDB_METADATA_CREDENTIALS="1"` — use the metadata service inside Yandex Cloud (Yandex Cloud Function or VM).
- `YDB_ACCESS_TOKEN_CREDENTIALS=<access_token>` — use token-based authentication.

Below are examples of authentication using environment variables in different YDB SDKs.

Go

Native SDK

```
package main

import (
  "context"
  "os"

  environ "github.com/ydb-platform/ydb-go-sdk-auth-environ"
  "github.com/ydb-platform/ydb-go-sdk/v3"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    environ.WithEnvironCredentials(ctx),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  ...
}
```

database/sql

```
package main

import (
  "context"
  "database/sql"
  "os"

  environ "github.com/ydb-platform/ydb-go-sdk-auth-environ"
  "github.com/ydb-platform/ydb-go-sdk/v3"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    environ.WithEnvironCredentials(ctx),
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)
  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }
  db := sql.OpenDB(connector)
  defer db.Close()
  ...
}
```

Java

Native SDK

```
public void work(String connectionString) {
    AuthProvider authProvider = new EnvironAuthProvider();

    try (GrpcTransport transport = GrpcTransport.forConnectionString(connectionString)
            .withAuthProvider(authProvider)
            .build();
         QueryClient queryClient = QueryClient.newClient(transport).build()) {

        doWork(queryClient);
    }
}
```

JDBC

```
public void work() throws SQLException {
    // No explicit credentials: the driver reads YDB_* environment variables in the order
    // described in [Authentication](../../reference/ydb-sdk/auth.md#env)
    try (Connection connection = DriverManager.getConnection("jdbc:ydb:grpc://localhost:2136/local", new Prop
erties())) {
        doWork(connection);
    }
}
```

In Spring Boot, ORMs, and other JDBC wrappers, use the same JDBC URL; credentials from the environment are picked up the same way as in the example above (for example via `spring.datasource.url`).

JavaScript

```
  import { Driver, getCredentialsFromEnv } from 'ydb-sdk';

  export async function connect(endpoint: string, database: string) {
      const authService = getCredentialsFromEnv();
      const driver = new Driver({endpoint, database, authService});
      const timeout = 10000;
      if (!await driver.ready(timeout)) {
          console.log(`Driver has not become ready in ${timeout}ms!`);
          process.exit(1);
      }
      console.log('Driver connected')
      return driver
  }
```

Python

Native SDK

```
import os
import ydb

with ydb.Driver(
    connection_string=os.environ["YDB_CONNECTION_STRING"],
    credentials=ydb.credentials_from_env_variables(),
) as driver:
    driver.wait(timeout=5)
    ...
```

Native SDK (Asyncio)

```
import os
import ydb
import asyncio

async def ydb_init():
    async with ydb.aio.Driver(
        endpoint=os.environ["YDB_ENDPOINT"],
        database=os.environ["YDB_DATABASE"],
        credentials=ydb.credentials_from_env_variables(),
    ) as driver:
        await driver.wait()
        ...

asyncio.run(ydb_init())
```

SQLAlchemy

```
import os
import sqlalchemy as sa
import ydb

engine = sa.create_engine(
    "yql+ydb://localhost:2136/local",
    connect_args={
        "credentials": ydb.credentials_from_env_variables()
    }
)
with engine.connect() as connection:
    result = connection.execute(sa.text("SELECT 1"))
```

PHP

```
<?php

use YdbPlatform\Ydb\Ydb;
use YdbPlatform\Ydb\Auth\EnvironCredentials;

$config = [

    // Database path
    'database'    => '/local',

    // Database endpoint
    'endpoint'    => 'localhost:2136',

    // Auto discovery (dedicated server only)
    'discovery'   => false,

    // IAM config
    'iam_config'  => [
        'insecure' => true,
        // 'root_cert_file' => './CA.pem', // Root CA file (uncomment for dedicated server)
    ],

    'credentials' => new EnvironCredentials()
];

$ydb = new Ydb($config);
```

Username and password based authentication

Below are examples of authentication with a username and password in different YDB SDKs.

C++

```
auto driverConfig = NYdb::TDriverConfig()
  .SetEndpoint(endpoint)
  .SetDatabase(database)
  .SetCredentialsProviderFactory(NYdb::CreateLoginCredentialsProviderFactory({
      .User = "user",
      .Password = "password",
  }));

NYdb::TDriver driver(driverConfig);
```

Go

Native SDK

You can pass the username and password in the connection string. For example:

```
"grpcs://login:password@localhost:2135/local"
```

You can also pass them explicitly using the `ydb.WithStaticCredentials` option:

```
package main

import (
  "context"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  db, err := ydb.Open(ctx,
      os.Getenv("YDB_CONNECTION_STRING"),
      ydb.WithStaticCredentials("user", "password"),
  )
  if err != nil {
      panic(err)
  }
  defer db.Close(ctx)
  ...
}
```

database/sql

You can pass the username and password in the connection string. For example:

```
package main

import (
  "context"

  _ "github.com/ydb-platform/ydb-go-sdk/v3"
)

func main() {
  db, err := sql.Open("ydb", "grpcs://login:password@localohost:2135/local")
  if err != nil {
      panic(err)
  }
  defer db.Close()
  ...
}
```

You can also pass them explicitly when initializing the driver via a connector using the `ydb.WithStaticCredentials` option:

```go
package main

import (
  "context"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  nativeDriver, err := ydb.Open(ctx,
      os.Getenv("YDB_CONNECTION_STRING"),
      ydb.WithStaticCredentials("user", "password"),
  )
  if err != nil {
      panic(err)
  }
  defer nativeDriver.Close(ctx)
  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }
  db := sql.OpenDB(connector)
  defer db.Close()
  ...
}
```

Java

Native SDK

```java
public void work(String connectionString, String username, String password) {
    StaticCredentials authProvider = new StaticCredentials(username, password);

    try (GrpcTransport transport = GrpcTransport.forConnectionString(connectionString)
            .withAuthProvider(authProvider)
            .build();
         QueryClient queryClient = QueryClient.newClient(transport).build()) {

        doWork(queryClient);
    }
}
```

JDBC

```java
public void work(String username, String password) throws SQLException {
    Properties props = new Properties();
    props.setProperty("username", username);
    props.setProperty("password", password);
    try (Connection connection = DriverManager.getConnection("jdbc:ydb:grpc://localhost:2136/local", props))
{
        doWork(connection);
    }

    // Username and password can be passed directly
    try (Connection connection = DriverManager.getConnection("jdbc:ydb:grpc://localhost:2136/local", usernam
e, password)) {
        doWork(connection);
    }
}
```

In Spring Boot, ORMs, and other JDBC wrappers, use the same JDBC URL, username, and password as above (for example `spring.datasource.url`, `spring.datasource.username`, `spring.datasource.password`, or the pool's equivalent settings).

JavaScript

```javascript
import { Driver } from "@ydbjs/core";
import { StaticCredentialsProvider } from "@ydbjs/auth/static";

const driver = new Driver("grpc://localhost:2136/local", {
  credentialsProvider: new StaticCredentialsProvider(
    { username: user, password: password },
    "grpc://localhost:2136",
  ),
});

await driver.ready();
```

Python

Native SDK

```python
import os
import ydb

config = ydb.DriverConfig(
    endpoint=os.environ["YDB_ENDPOINT"],
    database=os.environ["YDB_DATABASE"],
)

credentials = ydb.StaticCredentials(
    driver_config=config,
    user=os.environ["YDB_USER"],
    password=os.environ["YDB_PASSWORD"]
)

with ydb.Driver(driver_config=config, credentials=credentials) as driver:
    driver.wait(timeout=5)
    ...
```

Native SDK (Asyncio)

```python
import os
import ydb
import asyncio

config = ydb.DriverConfig(
    endpoint=os.environ["YDB_ENDPOINT"],
    database=os.environ["YDB_DATABASE"],
)

credentials = ydb.StaticCredentials(
    driver_config=config,
    user=os.environ["YDB_USER"],
    password=os.environ["YDB_PASSWORD"],
)

async def ydb_init():
    async with ydb.aio.Driver(driver_config=config, credentials=credentials) as driver:
        await driver.wait()
        ...

asyncio.run(ydb_init())
```

SQLAlchemy

```python
import os
import sqlalchemy as sa

engine = sa.create_engine(
    "yql+ydb://localhost:2136/local",
    connect_args={
        "credentials": {
            "username": os.environ["YDB_USER"],
            "password": os.environ["YDB_PASSWORD"]
        }
    }
)
with engine.connect() as connection:
    result = connection.execute(sa.text("SELECT 1"))
```

C# (.NET)

```csharp
using Ydb.Sdk;
using Ydb.Sdk.Auth;

const string endpoint = "grpc://localhost:2136";
const string database = "/local";

var config = new DriverConfig(
    endpoint: endpoint, // Database endpoint, "grpcs://host:port"
    database: database, // Full database path
    credentials: new StaticCredentialsProvider(user, password)
);

await using var driver = await Driver.CreateInitialized(config);
```

PHP

```php
<?php

use YdbPlatform\Ydb\Ydb;
use YdbPlatform\Ydb\Auth\Implement\StaticAuthentication;

$config = [

    // Database path
    'database'    => '/local',

    // Database endpoint
    'endpoint'    => 'localhost:2136',

    // Auto discovery (dedicated server only)
    'discovery'   => false,

    // IAM config
    'iam_config'  => [
        'insecure' => true,
        // 'root_cert_file' => './CA.pem', // Root CA file (uncomment for dedicated server)
    ],

    'credentials' => new StaticAuthentication($user, $password)
];

$ydb = new Ydb($config);
```

Balancing

YDB uses client load balancing because it is more efficient when a lot of traffic from multiple client applications comes to a database. In most cases, it just works in the YDB SDK. However, sometimes specific settings for client load balancing are required, for example, to reduce server hops and request time or to distribute the load across availability zones.

Note that custom balancing is limited when it comes to YDB sessions. Custom balancing in the YDB SDKs is performed only when creating a new YDB session on a specific node. Once the session is created, all queries in this session are passed to the node where the session was created. Queries in the same YDB session are not balanced between different YDB nodes.

This section contains code recipes with client load balancing settings in different YDB SDKs.

Table of contents:

- Random choice
- Prefer the nearest data center
- Prefer the specific availability zone
- Prefer a pile with a specific state

Random choice

The YDB SDK uses the `random_choice` (uniform random) balancing algorithm by default, except the C++ SDK, which defaults to "prefer the nearest data center".

Below are examples of explicitly setting the "random choice" balancing algorithm in different YDB SDKs.

Go

Native SDK

```
package main

import (
  "context"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/balancers"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithBalancer(
      balancers.RandomChoice(),
    ),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  // ...
}
```

database/sql

Client-side balancing in the YDB `database/sql` driver happens only when opening a new connection (in `database/sql` terms), which maps to a YDB session on a specific node. After the session is created, all queries on that session go to that node. Queries on the same YDB session are not balanced across nodes.

Example for "random choice" balancing:

```
package main

import (
  "context"
  "database/sql"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/balancers"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithBalancer(
      balancers.RandomChoice(),
    ),
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)

  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }

  db := sql.OpenDB(connector)
  defer db.Close()
  // ...
}
```

C++

```
#include <ydb-cpp-sdk/client/driver/driver.h>

int main() {
  auto connectionString = std::string(std::getenv("YDB_CONNECTION_STRING"));

  auto driverConfig = NYdb::TDriverConfig(connectionString)
    .SetBalancingPolicy(NYdb::TBalancingPolicy::UseAllNodes());

  NYdb::TDriver driver(driverConfig);
  // ...
  driver.Stop(true);
  return 0;
}
```

Python

Native SDK

```
import os
import ydb

driver_config = ydb.DriverConfig(
    endpoint=os.environ["YDB_ENDPOINT"],
    database=os.environ["YDB_DATABASE"],
    credentials=ydb.credentials_from_env_variables(),
    use_all_nodes=True,  # uniform random choice
)

with ydb.Driver(driver_config) as driver:
    driver.wait(timeout=5)
    # ...
```

Native SDK (Asyncio)

```
import os
import ydb
import asyncio

async def ydb_init():
    driver_config = ydb.DriverConfig(
        endpoint=os.environ["YDB_ENDPOINT"],
        database=os.environ["YDB_DATABASE"],
        credentials=ydb.credentials_from_env_variables(),
        use_all_nodes=True,  # uniform random choice
    )
    async with ydb.aio.Driver(driver_config) as driver:
        await driver.wait()
        # ...

asyncio.run(ydb_init())
```

SQLAlchemy

```
import os
import sqlalchemy as sa

engine = sa.create_engine(
    os.environ["YDB_SQLALCHEMY_URL"],
    connect_args={
        "driver_config_kwargs": {
            "use_all_nodes": True,  # uniform random choice
        }
    },
)
```

JavaScript

This section is under development.

Java

Native SDK

"Random choice" in the Java SDK corresponds to the `USE_ALL_NODES` policy in `BalancingSettings` (this is also the default if you do not override settings).

```
import tech.ydb.core.grpc.BalancingSettings;
import tech.ydb.core.grpc.GrpcTransport;

try (GrpcTransport transport = GrpcTransport.forConnectionString("grpc://localhost:2136/local")
        .withBalancingSettings(BalancingSettings.fromPolicy(BalancingSettings.Policy.USE_ALL_NODES))
        .build()) {
    // ...
}
```

JDBC

Balancing when selecting a new session is handled by the native transport inside the driver; if needed, use the same parameters as in the native SDK via JDBC connection settings.

In Spring Boot, ORMs, and other JDBC wrappers, use the same JDBC URL and balancing parameters as with the driver directly (for example `spring.datasource.url` with query parameters or `DataSource` properties).

Rust

The RandomChoice policy (random endpoint selection among discovery nodes) is enabled **by default** — no extra configuration is required.

Prefer the nearest data center

Below are examples of setting the "prefer the nearest data center" balancing algorithm in different YDB SDKs.

Go

Native SDK

```
package main

import (
  "context"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/balancers"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithBalancer(
      balancers.PreferLocalDC(
        balancers.RandomChoice(),
      ),
    ),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  // ...
}
```

database/sql

Client-side balancing in the YDB `database/sql` driver happens only when opening a new connection (in `database/sql` terms), which corresponds to a YDB session on a specific node. After the session is created, all queries on that session go to that node. Queries on the same YDB session are not balanced across nodes.

Example for "prefer the nearest data center" balancing:

```
package main

import (
  "context"
  "database/sql"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/balancers"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithBalancer(
      balancers.PreferLocalDC(
        balancers.RandomChoice(),
      ),
    ),
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)

  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }

  db := sql.OpenDB(connector)
  defer db.Close()
  // ...
}
```

C++

The YDB C++ SDK uses the `prefer_local_dc` (prefer nearest data center) algorithm by default.

```cpp
#include <ydb-cpp-sdk/client/driver/driver.h>

int main() {
  auto connectionString = std::string(std::getenv("YDB_CONNECTION_STRING"));

  auto driverConfig = NYdb::TDriverConfig(connectionString)
    .SetBalancingPolicy(NYdb::TBalancingPolicy::UsePreferableLocation());

  NYdb::TDriver driver(driverConfig);
  // ...
  driver.Stop(true);
  return 0;
}
```

Python

Native SDK

```python
import os
import ydb

driver_config = ydb.DriverConfig(
    endpoint=os.environ["YDB_ENDPOINT"],
    database=os.environ["YDB_DATABASE"],
    credentials=ydb.credentials_from_env_variables(),
    use_all_nodes=False,  # prefer the nearest data center
)

with ydb.Driver(driver_config) as driver:
    driver.wait(timeout=5)
    # ...
```

Native SDK (Asyncio)

```python
import os
import ydb
import asyncio

async def ydb_init():
    driver_config = ydb.DriverConfig(
        endpoint=os.environ["YDB_ENDPOINT"],
        database=os.environ["YDB_DATABASE"],
        credentials=ydb.credentials_from_env_variables(),
        use_all_nodes=False,  # prefer the nearest data center
    )
    async with ydb.aio.Driver(driver_config) as driver:
        await driver.wait()
        # ...

asyncio.run(ydb_init())
```

SQLAlchemy

```python
import os
import sqlalchemy as sa

engine = sa.create_engine(
    os.environ["YDB_SQLALCHEMY_URL"],
    connect_args={
        "driver_config_kwargs": {
            "use_all_nodes": False,  # prefer the nearest data center
        }
    },
)
```

JavaScript

This section is under development.

Java

Native SDK

```java
import tech.ydb.core.grpc.BalancingSettings;
import tech.ydb.core.grpc.GrpcTransport;

try (GrpcTransport transport = GrpcTransport.forConnectionString("grpc://localhost:2136/local")
        .withBalancingSettings(BalancingSettings.detectLocalDs())
        .build()) {
    // ...
}
```

JDBC

See JDBC driver properties; configure balancing via the native transport if needed.

In Spring Boot, ORMs, and other JDBC wrappers, use the same JDBC URL and balancing settings as with the driver directly (for example `spring.datasource.url` or `DataSource` properties).

Rust

This functionality is not currently supported.

Track progress or vote for Rust SDK support: ydb-rs-sdk#239

Prefer a specific availability zone

Below are examples of setting the "prefer availability zone" balancing algorithm in different YDB SDKs.

Go

Native SDK

```
package main

import (
  "context"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/balancers"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithBalancer(
      balancers.PreferLocations(
        balancers.RandomChoice(),
        "a",
        "b",
      ),
    ),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  // ...
}
```

database/sql

Client-side balancing in the YDB `database/sql` driver happens only when opening a new connection (in `database/sql` terms), which maps to a YDB session on a specific node. After the session is created, all queries on that session go to that node. Queries on the same YDB session are not balanced across nodes.

Example for "prefer availability zone" balancing:

```
package main

import (
  "context"
  "database/sql"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/balancers"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithBalancer(
      balancers.PreferLocations(
        balancers.RandomChoice(),
        "a",
        "b",
      ),
    ),
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)

  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }

  db := sql.OpenDB(connector)
  defer db.Close()
  // ...
}
```

C++

The C++ SDK lets you pick only one availability zone as preferred.

```cpp
#include <ydb-cpp-sdk/client/driver/driver.h>

int main() {
  auto connectionString = std::string(std::getenv("YDB_CONNECTION_STRING"));

  auto driverConfig = NYdb::TDriverConfig(connectionString)
    .SetBalancingPolicy(NYdb::TBalancingPolicy::UsePreferableLocation("datacenter1"));

  NYdb::TDriver driver(driverConfig);
  // ...
  driver.Stop(true);
  return 0;
}
```

Python

This functionality is not currently supported.

JavaScript

This section is under development.

Java

In the **Java SDK**, availability zone preference is set on the gRPC transport.

Native SDK

```java
import tech.ydb.core.grpc.BalancingSettings;
import tech.ydb.core.grpc.GrpcTransport;

try (GrpcTransport transport = GrpcTransport.forConnectionString("grpc://localhost:2136/local")
        .withBalancingSettings(BalancingSettings.fromLocation("a")) // preferred availability zone
        .build()) {
    // ...
}
```

JDBC

See supported availability-zone parameters in JDBC driver properties, or configure balancing through the native API when embedding the driver.

In Spring Boot, ORMs, and other JDBC wrappers, pass the same JDBC URL and zone parameters as for a direct connection (for example in `spring.datasource.url` or pool properties).

Rust

This functionality is not currently supported.

Track progress or vote for Rust SDK support: ydb-rs-sdk#238

Prefer a pile with a specific state

Below is an example of setting the balancing algorithm option that prefers a pile in a given state in the YDB SDK.

If no state is specified when setting the option, the SDK prefers the PRIMARY pile.

This option only makes sense if the cluster is operating in bridge mode. Otherwise, the SDK uses random choice balancing.

Go

This functionality is not currently supported.

C++

```
#include <ydb-cpp-sdk/client/driver/driver.h>

int main() {
  auto connectionString = std::string(std::getenv("YDB_CONNECTION_STRING"));

  auto driverConfig = NYdb::TDriverConfig(connectionString)
    .SetBalancingPolicy(NYdb::TBalancingPolicy::UsePreferablePileState(NYdb::EPileState::PRIMARY));

  NYdb::TDriver driver(driverConfig);
  // ...
  driver.Stop(true);
  return 0;
}
```

Python

This functionality is not currently supported.

JavaScript

This section is under development.

Java

This functionality is not currently supported.

Rust

This functionality is not currently supported.

Track progress or vote for Rust SDK support: ydb-rs-sdk#491

Retrying

YDB is a distributed database management system with automatic load scaling.
Routine maintenance can be carried out on the server side, with server racks or entire data centers temporarily shut down.
This may result in errors when working with YDB.
Depending on the error type, you should respond differently.
YDB SDKs provide built-in tools for retries to ensure high availability,
with error types accounted for and defined handling for them.

Below are code examples showing the YDB SDK built-in tools for retries:

C++

In the YDB C++ SDK, retries with correct error handling is implemented by several programming interfaces:

Synchronous retry attempts

The `RetryQuerySync` method is used to execute queries with automatic retries.
The method accepts a lambda function that receives a session object and returns the query result.
YDB C++ SDK automatically analyzes errors and performs retries according to their type.

Example code using `RetryQuerySync`:

```
#include <ydb-cpp-sdk/client/query/client.h>

void ExecuteQueryWithRetry(NYdb::NQuery::TQueryClient client) {
    auto result = client.RetryQuerySync([](NYdb::NQuery::TSession session) -> NYdb::TStatus {
        auto query = R"(
            SELECT series_id, title
            FROM series
            WHERE series_id = 1;
        )";

        auto result = session.ExecuteQuery(
            query,
            NYdb::NQuery::TTxControl::BeginTx(NYdb::NQuery::TTxSettings::SerializableRW()).CommitTx()
        ).GetValueSync();

        if (!result.IsSuccess()) {
            return result;
        }

        // Process query results
        auto resultSet = result.GetResultSet(0);
        NYdb::TResultSetParser parser(resultSet);
        while (parser.TryNextRow()) {
            std::cout << "Series"
                << ", Id: " << parser.ColumnParser("series_id").GetOptionalUint64().value()
                << ", Title: " << parser.ColumnParser("title").GetOptionalUtf8().value()
                << std::endl;
        }

        return result;
    });

    if (!result.IsSuccess()) {
        // Handle error after all retry attempts
        std::cerr << "Query failed: " << result.GetIssues().ToString() << std::endl;
    }
}
```

Asynchronous retry attempts

The `RetryQuery` method is used for asynchronous query execution with automatic retries.
The method returns `NThreading::TFuture`, which allows for asynchronous operations.

Example code using `RetryQuery`:

```cpp
#include <ydb-cpp-sdk/client/query/client.h>

void ExecuteQueryWithRetryAsync(NYdb::NQuery::TQueryClient client) {
    auto future = client.RetryQuery([](NYdb::NQuery::TSession session) -> NYdb::TAsyncStatus {
        auto query = R"(
            SELECT series_id, title, release_date
            FROM series
            WHERE series_id = 1;
        )";

        return session.ExecuteQuery(
            query,
            NYdb::NQuery::TTxControl::BeginTx(NYdb::NQuery::TTxSettings::SerializableRW()).CommitTx()
        ).Apply([](const NYdb::NQuery::TAsyncExecuteQueryResult& asyncResult) -> NYdb::TStatus {
            auto result = asyncResult.GetValue();
            if (!result.IsSuccess()) {
                return result;
            }

            // Process query results
            auto resultSet = result.GetResultSet(0);
            NYdb::TResultSetParser parser(resultSet);
            while (parser.TryNextRow()) {
                std::cout << "Series"
                    << ", Id: " << parser.ColumnParser("series_id").GetOptionalUint64().value()
                    << ", Title: " << parser.ColumnParser("title").GetOptionalUtf8().value()
                    << std::endl;
            }

            return result;
        });
    });

    // Wait for completion
    auto status = future.GetValueSync();
    if (!status.IsSuccess()) {
        std::cerr << "Query failed: " << status.GetIssues().ToString() << std::endl;
    }
}
```

Retry attempts for streaming queries

For executing streaming queries with automatic retries, use `StreamExecuteQuery`.
Streaming queries allow processing large volumes of data by receiving results in parts.

Example code using `RetryQuerySync` with `StreamExecuteQuery`:

```cpp
#include <ydb-cpp-sdk/client/query/client.h>

void StreamQueryWithRetry(NYdb::NQuery::TQueryClient client) {
    auto result = client.RetryQuerySync([](NYdb::NQuery::TSession session) -> NYdb::TStatus {
        auto query = R"(
            SELECT series_id, title, release_date
            FROM series
            WHERE series_id > 0;
        )";

        auto resultStreamQuery = session.StreamExecuteQuery(
            query,
            NYdb::NQuery::TTxControl::NoTx()
        ).GetValueSync();

        if (!resultStreamQuery.IsSuccess()) {
            return resultStreamQuery;
        }

        // Process results in parts
        bool eos = false;
        while (!eos) {
            auto streamPart = resultStreamQuery.ReadNext().ExtractValueSync();

            if (!streamPart.IsSuccess()) {
                eos = true;
                if (!streamPart.EOS()) {
                    return streamPart;
                }
                continue;
            }

            if (streamPart.HasResultSet()) {
                auto rs = streamPart.ExtractResultSet();
                NYdb::TResultSetParser parser(rs);
                while (parser.TryNextRow()) {
                    std::cout << "Series"
                        << ", Id: " << parser.ColumnParser("series_id").GetOptionalUint64().value()
                        << ", Title: " << parser.ColumnParser("title").GetOptionalUtf8().value()
                        << std::endl;
                }
            }
        }

        return resultStreamQuery;
    });

    if (!result.IsSuccess()) {
        std::cerr << "Stream query failed: " << result.GetIssues().ToString() << std::endl;
    }
}
```

Configuring retry parameters

Users can configure the behavior of the retry mechanism using the `TRetryOperationSettings` class:

- `MaxRetries(uint32_t)` - maximum number of retry attempts (default is 10)
- `Idempotent(bool)` - indicates whether the operation is idempotent. Idempotent operations are retried for a broader range of errors
- `RetryNotFound(bool)` - whether to retry operations that returned a `NOT_FOUND` status (default is true)
- `MaxTimeout(TDuration)` - maximum time for all retry attempts
- `FastBackoffSettings(TBackoffSettings)` - settings for fast retries
- `SlowBackoffSettings(TBackoffSettings)` - settings for slow retries

Example of using retry settings:

```cpp
#include <ydb-cpp-sdk/client/query/client.h>
#include <ydb-cpp-sdk/client/retry/retry.h>

void ExecuteWithCustomRetry(NYdb::NQuery::TQueryClient client) {
    auto retrySettings = NYdb::NRetry::TRetryOperationSettings()
        .Idempotent(true)
        .MaxRetries(20)
        .MaxTimeout(TDuration::Seconds(30));

    auto result = client.RetryQuerySync([](NYdb::NQuery::TSession session) -> NYdb::TStatus {
        auto query = R"(
            UPSERT INTO series (series_id, title)
            VALUES (10, "New Series");
        )";

        auto result = session.ExecuteQuery(
            query,
            NYdb::NQuery::TTxControl::BeginTx(NYdb::NQuery::TTxSettings::SerializableRW()).CommitTx()
        ).GetValueSync();

        if (!result.IsSuccess()) {
            return result;
        }

        // Process query result
        std::cout << "Query executed successfully" << std::endl;
        return result;
    }, retrySettings);

    if (!result.IsSuccess()) {
        std::cerr << "Operation failed: " << result.GetIssues().ToString() << std::endl;
    }
}
```

Go

Native SDK

In the YDB Go SDK, correct error handling is implemented by several programming interfaces:

General-purpose repeat function

The basic logic of error handling is implemented by the helper `retry.Retry` function.
The details of repeat query execution are mostly hidden.

The user can affect the logic of the `retry.Retry` function in two ways:

- Via the context (where you can set the deadline and cancel)
- Via the operation's idempotency flag `retry.WithIdempotent()`. By default, the operation is considered non-idempotent.

The user passes a custom function to `retry.Retry` that returns an error by its signature.
If the custom function returns `nil`, then repeat queries stop.
If the custom function returns an error, the YDB Go SDK tries to identify this error and executes retries depending on it.

Example of the code that uses the `retry.Retry` function:

```
package main

import (
  "context"
  "time"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/retry"
)

func main() {
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  var cancel context.CancelFunc
  // fix deadline for retries
  ctx, cancel := context.WithTimeout(ctx, time.Second)
  err = retry.Retry(
    ctx,
    func(ctx context.Context) error {
      whoAmI, err := db.Discovery().WhoAmI(ctx)
      if err != nil {
        return err
      }
      fmt.Println(whoAmI)
      return nil
    },
    retry.WithIdempotent(true),
  )
  if err != nil {
    panic(err)
  }
}
```

Repeat attempts in case of failed YDB session objects

For repeat error handling at the level of a YDB table service session, you can use the `db.Table().Do(ctx, op)` function, which provides a prepared session for query execution.
`db.Table().Do(ctx, op)` uses the `retry` package and tracks the lifetime of the YDB sessions.
Based on its signature, the user's operation `op` should return an error or `nil` so that the driver can "decide" what to do based on the error type: repeat the operation or not, with delay or without, and in this session or a new one.
The user can affect the logic of repeat queries using the context and the idempotence flag, while the YDB Go SDK interprets errors returned by `op`.

Example of the code that uses the `db.Table().Do(ctx, op)` function:

```
err := db.Table().Do(ctx, func(ctx context.Context, s table.Session) (err error) {
  desc, err = s.DescribeTableOptions(ctx)
  return
}, table.WithIdempotent())
if err != nil {
  return err
}
```

Repeat attempts in case of failed YDB interactive transaction objects

For repeat error handling at the level of a YDB table service interactive transaction, you can use the `db.Table().DoTx(ctx, txOp)` function, which provides a YDB prepared session transaction for query execution.
`db.Table().DoTx(ctx, txOp)` uses the `retry` package and tracks the lifetime of the YDB sessions.
Based on its signature, the user's operation `txOp` should return an error or `nil` so that the driver can "decide" what to do based on the error type: repeat the operation or not, with delay or without, and in this transaction or a new one.
The user can affect the logic of repeat queries using the context and the idempotence flag, while the YDB Go SDK interprets errors returned by `op`.

Example of the code that uses the `db.Table().DoTx(ctx, op)` function:

```
err := db.Table().DoTx(ctx, func(ctx context.Context, tx table.TransactionActor) error {
  _, err := tx.Execute(ctx,
    "DECLARE $id AS Int64; INSERT INTO test (id, val) VALUES($id, 'asd')",
    table.NewQueryParameters(table.ValueParam("$id", types.Int64Value(100500))),
  )
  return err
}, table.WithIdempotent())
if err != nil {
  return err
}
```

Queries to other YDB services

(`db.Scripting()` , `db.Scheme()` , `db.Coordination()` , `db.Ratelimiter()` , `db.Discovery()`) also use the `retry.Retry` function inside to execute repeat queries and don't require external auxiliary functions for repeats.

database/sql

The standard `database/sql` package uses the internal logic of repeats based on the errors a specific driver implementation returns. For example, the `database/sql` code frequently shows the three-attempt repeats policy:

- Two attempts at a present connection or new one (if the `database/sql` connection pool is empty).
- One attempt at a new connection.

This repeat policy is mostly enough to survive temporary unavailability of YDB nodes or issues with a YDB session.

The YDB Go SDK provides special functions to ensure execution of a user's operation:

Repeat attempts in case of failed `*sql.Conn` connection objects:

For repeat error handling at `*sql.Conn` connection objects, you can use the auxiliary `retry.Do(ctx, db, op)` function, which provides a prepared `*sql.Conn` session for query execution.
You need to pass the context, database object, and the user's operation for execution to the `retry.Do` function.
The user's code can affect the logic of repeat queries using the context and the idempotence flag, while the YDB Go SDK, in turn, interprets errors returned by `op` .

The user's `op` operation must return an error or `nil` :

- If the custom function returns `nil` , then repeat queries stop.
- If the custom function returns an error, the YDB Go SDK tries to identify this error and performs retries depending on it.

Example of the code that uses the `retry.Do` function:

```
import (
  "context"
  "database/sql"
  "fmt"
  "log"

  "github.com/ydb-platform/ydb-go-sdk/v3/retry"
)

func main() {
  ...
  err = retry.Do(ctx, db, func(ctx context.Context, cc *sql.Conn) (err error) {
    row = cc.QueryRowContext(ctx, `
        PRAGMA TablePathPrefix("/local");
        DECLARE $seriesID AS Uint64;
        DECLARE $seasonID AS Uint64;
        DECLARE $episodeID AS Uint64;
        SELECT views FROM episodes WHERE series_id = $seriesID AND season_id = $seasonID AND episode_id =
$episodeID;
      `,
      sql.Named("seriesID", uint64(1)),
      sql.Named("seasonID", uint64(1)),
      sql.Named("episodeID", uint64(1)),
    )
    var views sql.NullFloat64
    if err = row.Scan(&views); err != nil {
      return fmt.Errorf("cannot scan views: %w", err)
    }
    if views.Valid {
      return fmt.Errorf("unexpected valid views: %v", views.Float64)
    }
    log.Printf("views = %v", views)
    return row.Err()
  }, retry.WithDoRetryOptions(retry.WithIdempotent(true)))
  if err != nil {
    log.Printf("retry.Do failed: %v\n", err)
  }
}
```

Repeat attempts in case of failed `*sql.Tx` interactive transaction objects:

For repeat error handling at `*sql.Tx` interactive transaction objects, you can use the auxiliary `retry.DoTx(ctx, db, op)` function, which provides a prepared `*sql.Tx` transaction for query execution.
You need to pass the context, database object, and the user's operation for execution to the `retry.DoTx` function.
The function is passed a prepared `*sql.Tx` transaction, where queries to YDB should be executed.
The user's code can affect the logic of repeat queries using the context and the operation idempotence flag, while the YDB Go SDK, in turn, interprets errors returned by `op` .

The user's `op` operation must return an error or `nil` :

- If the custom function returns `nil` , then repeat queries stop.
- If the custom function returns an error, the YDB Go SDK tries to identify this error and performs retries depending on it.

By default, `retry.DoTx` uses the read-write isolation mode of the `sql.LevelDefault` transaction and you can change it using the `retry.WithTxOptions` parameter.

Example of the code that uses the `retry.Do` function:

```
import (
  "context"
  "database/sql"
  "fmt"
  "log"

  "github.com/ydb-platform/ydb-go-sdk/v3/retry"
)

func main() {
  ...
  err = retry.DoTx(ctx, db, func(ctx context.Context, tx *sql.Tx) error {
    row := tx.QueryRowContext(ctx,`
        PRAGMA TablePathPrefix("/local");
        DECLARE $seriesID AS Uint64;
        DECLARE $seasonID AS Uint64;
        DECLARE $episodeID AS Uint64;
        SELECT views FROM episodes WHERE series_id = $seriesID AND season_id = $seasonID AND episode_id =
$episodeID;
      `,
      sql.Named("seriesID", uint64(1)),
      sql.Named("seasonID", uint64(1)),
      sql.Named("episodeID", uint64(1)),
    )
    var views sql.NullFloat64
    if err = row.Scan(&views); err != nil {
      return fmt.Errorf("cannot select current views: %w", err)
    }
    if !views.Valid {
      return fmt.Errorf("unexpected invalid views: %v", views)
    }
    t.Logf("views = %v", views)
    if views.Float64 != 1 {
      return fmt.Errorf("unexpected views value: %v", views)
    }
    return nil
  }, retry.WithDoTxRetryOptions(retry.WithIdempotent(true)), retry.WithTxOptions(&sql.TxOptions{
    Isolation: sql.LevelSnapshot,
    ReadOnly:  true,
  }))
  if err != nil {
    log.Printf("do tx failed: %v\n", err)
  }
}
```

Java

Native SDK

In the YDB Java SDK, repeat queries are implemented by the `SessionRetryContext` helper class. This class is constructed with the `SessionRetryContext.create` method to which you pass the `SessionSupplier` interface implementation (usually an instance of the `TableClient` class or the `QueryClient` class).

Additionally, the user can specify some other options:

- `maxRetries(int maxRetries)`: The maximum number of operation retries, not counting the first execution. Default value: `10`
- `retryNotFound(boolean retryNotFound)`: The option to retry operations that returned the `NOT_FOUND` status. Enabled by default.
- `idempotent(boolean idempotent)`: Indicates idempotence of operations. Idempotent operations will be retried for a broader range of errors. Disabled by default.

The `SessionRetryContext` class provides two methods to run operations with retries.

- `CompletableFuture<Status> supplyStatus`: Executing the operation that returns the status. As an argument, it accepts the lambda `Function<Session, CompletableFuture<Status>> fn`
- `CompletableFuture<Result<T>> supplyResult`: Executing the operation that returns data. As an argument, it accepts the lambda `Function<Session, CompletableFuture<Result<T>>> fn`

When using the `SessionRetryContext` class, make sure that the operation will be retried in the following cases:

- The lambda function returned a retryable error code
- The lambda function invoked an `UnexpectedResultException` with a retryable error code

Sample code using SessionRetryContext.supplyStatus:

```
private void createTable(TableClient tableClient, String database, String tableName) {
    SessionRetryContext retryCtx = SessionRetryContext.create(tableClient).build();
    TableDescription pets = TableDescription.newBuilder()
            .addNullableColumn("species", PrimitiveType.Text)
            .addNullableColumn("name", PrimitiveType.Text)
            .addNullableColumn("color", PrimitiveType.Text)
            .addNullableColumn("price", PrimitiveType.Float)
            .setPrimaryKeys("species", "name")
            .build();

    String tablePath = database + "/" + tableName;
    retryCtx.supplyStatus(session -> session.createTable(tablePath, pets))
            .join().expectSuccess();
}
```

Sample code using SessionRetryContext.supplyResult:

```
private void selectData(TableClient tableClient, String tableName) {
    SessionRetryContext retryCtx = SessionRetryContext.create(tableClient).build();
    String selectQuery
            = "DECLARE $species AS Text;"
            + "DECLARE $name AS Text;"
            + "SELECT * FROM " + tableName + " "
            + "WHERE species = $species AND name = $name;";

    Params params = Params.of(
            "$species", PrimitiveValue.newText("cat"),
            "$name", PrimitiveValue.newText("Tom")
    );

    DataQueryResult data = retryCtx
            .supplyResult(session -> session.executeDataQuery(selectQuery, TxControl.onlineRo(), params))
            .join().getValue();

    ResultSetReader rsReader = data.getResultSet(0);
    logger.info("Result of select query:");
    while (rsReader.next()) {
        logger.info("  species: {}, name: {}, color: {}, price: {}",
                rsReader.getColumn("species").getText(),
                rsReader.getColumn("name").getText(),
                rsReader.getColumn("color").getText(),
                rsReader.getColumn("price").getFloat()
        );
    }
}
```

JDBC

Retries at the `SessionRetryContext` level apply to the native API (`TableClient` / `QueryClient`). When using JDBC, implement retries at the application level or use native transport and clients as in Driver initialization.

Python

Native SDK

In the YDB Python SDK, retries are implemented in `QuerySessionPool` using the `RetrySettings` class. `RetrySettings` supports:

- `max_retries` — maximum number of retries (default 10)
- `idempotent` — whether the operation is idempotent; idempotent operations are retried for a broader set of errors (default False)
- `backoff_ceiling`, `backoff_slot_duration` — parameters for exponential backoff
- `fast_backoff_settings`, `slow_backoff_settings` — fast and slow retry tuning

For queries with retries, `QuerySessionPool` provides `retry_operation_sync` and `execute_with_retries`. Use `execute_with_retries` for one-off queries in implicit transaction mode. For explicit transactions or multiple operations in one transaction, use `retry_operation_sync`.

Example using `execute_with_retries`:

```
import ydb

def execute_query(pool: ydb.QuerySessionPool):
    result_sets = pool.execute_with_retries(
        "SELECT series_id, title FROM series WHERE series_id = 1;",
        retry_settings=ydb.RetrySettings(idempotent=True),
    )
    # ...
```

Example using `retry_operation_sync`:

```
import ydb

def execute_query(pool: ydb.QuerySessionPool):
    def callee(session: ydb.QuerySession):
          with session.transaction().execute(
              "SELECT 1",
              commit_tx=True,
          ) as result_sets:
              pass

    result = pool.retry_operation_sync(
        callee,
        retry_settings=ydb.RetrySettings(max_retries=20, idempotent=True),
    )
    # ...
```

Native SDK (Asyncio)

Example using `execute_with_retries`:

```
import ydb

async def execute_query(pool: ydb.aio.QuerySessionPool):
    result_sets = await pool.execute_with_retries(
        "SELECT series_id, title FROM series WHERE series_id = 1;",
        retry_settings=ydb.RetrySettings(idempotent=True),
    )
    # ...
```

Example using `retry_operation_sync`:

```
import ydb

async def execute_query(pool: ydb.aio.QuerySessionPool):
    async def callee(session):
        async with session.transaction(tx_mode=ydb.QuerySerializableReadWrite()) as tx:
            async with await tx.execute("SELECT 1", commit_tx=True) as result_sets:
                pass

    await pool.retry_operation_async(
        callee,
        retry_settings=ydb.RetrySettings(max_retries=20, idempotent=True),
    )
    # ...
```

SQLAlchemy

When using YDB through SQLAlchemy, retries happen internally and are not configured from the outside.

Rust

`QueryClient` automatically retries methods that execute a single transactional SQL statement (`query_row`, `exec`, and similar). For multiple operations in one transaction, use `retry_transaction`.

```
use ydb::{AccessTokenCredentials, ClientBuilder, YdbResult};

#[tokio::main]
async fn main() -> YdbResult<()> {
    let client = ClientBuilder::new_from_connection_string(
        "grpc://localhost:2136/local",
    )?
    .with_credentials(AccessTokenCredentials::from("..."))
    .client()?;

    client.wait().await?;

    let mut qc = client.query_client().clone_with_idempotent_operations(true);

    // query_row / exec: internal retries
    let mut row = qc
        .query_row("SELECT series_id, title FROM series WHERE series_id = 1")
        .await?;

    // multiple operations in one retried transaction
    let title: String = qc
        .retry_transaction(async |tx| {
            let mut row = tx
                .query_row("SELECT series_id, title FROM series WHERE series_id = 1")
                .await?;
            Ok(row.remove_field_by_name("title")?.try_into()?)
        })
        .await?;

    Ok(())
}
```

JavaScript

Retries and reconnections are built into the SDK; you do not need to configure anything separately.

The retrier is available in the separate `@ydbjs/retry` package.

```
import { retry } from '@ydbjs/retry'

let attempts = 0
const result = retry({ retry: isError, budget: 3 }, async () => {
  if (attempts >= 2) {
    return 'success'
  }

  attempts++
  throw new Error('test error')
})
```

Setting the session pool size

YDB creates an actor for each session. Consequently, the session pool size on the client affects resource consumption (memory, CPU) on the YDB server.

For example, if 1000 clients of the same database open 1000 sessions each, one million actors are created on the server, consuming a large amount of memory and CPU. Without a client-side session limit, this can slow the cluster down and put it in a degraded state.

By default, native YDB SDK drivers use a limit of 50 sessions. When using third-party libraries such as Go `database/sql`, no limit is set.

Set the client session limit to the minimum needed for normal application operation. Remember that a session is single-threaded on both server and client. If the application must run 1000 concurrent in-flight requests to YDB, set the limit to about 1000 sessions.

Distinguish estimated RPS (requests per second) from in-flight requests. RPS is the total number of requests completed in one second. For example, with RPS = 10000 and average latency 100 ms, a limit of 1000 sessions is enough: each session can run about 10 sequential requests per second on average.

Below are examples of setting the session pool limit in different YDB SDKs.

Go

Native SDK

```
package main

import (
  "context"

  "github.com/ydb-platform/ydb-go-sdk/v3"
)

func main() {
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithSessionPoolSizeLimit(500),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  ...
}
```

database/sql

The `database/sql` library has its own connection pool. Each `database/sql` connection maps to one YDB session. Tune the pool with `sql.DB.SetMaxOpenConns` and `sql.DB.SetMaxIdleConns`. See the `database/sql` documentation.

Example using a `database/sql` connection pool:

```
package main

import (
  "context"
  "database/sql"

  _ "github.com/ydb-platform/ydb-go-sdk/v3"
)

func main() {
  db, err := sql.Open("ydb", os.Getenv("YDB_CONNECTION_STRING"))
  if err != nil {
    panic(err)
  }
  defer db.Close()
  db.SetMaxOpenConns(100)
  db.SetMaxIdleConns(100)
  db.SetConnMaxIdleTime(time.Second) // workaround for background keep-aliving of YDB sessions
  ...
}
```

Java

Native SDK

```
this.queryClient = QueryClient.newClient(transport)
        // 10 — minimum active sessions kept in the pool during cleanup
        // 500 — maximum pool size
        .sessionPoolMinSize(10)
        .sessionPoolMaxSize(500)
        .build();
```

JDBC

JDBC applications typically use external connection pools such as HikariCP or C3p0. By default, the YDB JDBC driver observes how many connections the external pool opens and adjusts the session pool accordingly. Configure session limits by configuring HikariCP or C3p0 correctly.

Example HikariCP settings in Spring:

```
spring.datasource.url=jdbc:ydb:grpc://localhost:2136/local
spring.datasource.driver-class-name=tech.ydb.jdbc.YdbDriver
spring.datasource.hikari.maximum-pool-size=100 # max JDBC connections
```

Python

Native SDK

```python
import os
import ydb

with ydb.Driver(
    connection_string=os.environ["YDB_CONNECTION_STRING"],
    credentials=ydb.credentials_from_env_variables(),
) as driver:
    driver.wait(timeout=5)
    with ydb.QuerySessionPool(driver, size=500) as pool:
        # ...
```

Native SDK (Asyncio)

```python
import os
import ydb
import asyncio

async def ydb_init():
    async with ydb.aio.Driver(
        connection_string=os.environ["YDB_CONNECTION_STRING"],
        credentials=ydb.credentials_from_env_variables(),
    ) as driver:
        await driver.wait()
        async with ydb.aio.QuerySessionPool(driver, size=500) as pool:
            # ...

asyncio.run(ydb_init())
```

SQLAlchemy

Setting the pool size is not currently supported.

JavaScript

This section is under development.

Rust

For `QueryClient`, set the session pool size via `QuerySessionPoolSettings::with_limit` and `with_implicit_session_pool` (or `with_session_pool` for explicit sessions):

```rust
use ydb::{ClientBuilder, QuerySessionPoolSettings, YdbResult};

#[tokio::main]
async fn main() -> YdbResult<()> {
    let client = ClientBuilder::new_from_connection_string(
        std::env::var("YDB_CONNECTION_STRING")?,
    )?
    .client()?;
    client.wait().await?;

    let mut qc = client
        .query_client()
        .with_implicit_session_pool(
            QuerySessionPoolSettings::new().with_limit(500),
        );

    let mut row = qc.query_row("SELECT 1 AS one").await?;
    Ok(())
}
```

Upsert data

Below are code examples of using the built-in upsert tools of the YDB SDK:

C++

Native SDK

```
#include <ydb-cpp-sdk/client/query/client.h>

void UpsertSeries(NYdb::NQuery::TQueryClient& client) {
  NYdb::NStatusHelpers::ThrowOnError(client.RetryQuerySync(
      [](NYdb::NQuery::TSession session) {
          constexpr auto query = R"(
              DECLARE $seriesData AS List<Struct<
                  series_id: Uint64,
                  title: Utf8,
                  series_info: Utf8,
                  comment: Optional<Utf8>
              >>;

              UPSERT INTO series
              (
                  series_id,
                  title,
                  series_info,
                  comment
              )
              SELECT
                  series_id,
                  title,
                  series_info,
                  comment
              FROM AS_TABLE($seriesData);
          )";

          auto params = NYdb::TParamsBuilder()
              .AddParam("$seriesData")
                  .BeginList()
                  .AddListItem()
                      .BeginStruct()
                      .AddMember("series_id").Uint64(1)
                      .AddMember("title").Utf8("IT Crowd")
                      .AddMember("series_info").Utf8(
                          "The IT Crowd is a British sitcom produced by Channel 4, written by Graham Linehan,
produced by "
                          "Ash Atalla and starring Chris O'Dowd, Richard Ayoade, Katherine Parkinson, and Mat
t Berry.")
                      .AddMember("comment").OptionalUtf8(std::nullopt)
                      .EndStruct()
                  .AddListItem()
                      .BeginStruct()
                      .AddMember("series_id").Uint64(2)
                      .AddMember("title").Utf8("Silicon Valley")
                      .AddMember("series_info").Utf8(
                          "Silicon Valley is an American comedy television series created by Mike Judge, John
Altschuler and "
                          "Dave Krinsky. The series focuses on five young men who founded a startup company i
n Silicon Valley.")
                      .AddMember("comment").OptionalUtf8("lorem ipsum")
                      .EndStruct()
                  .EndList()
                  .Build()
              .Build();

          return session.ExecuteQuery(
              query,
              NYdb::NQuery::TTxControl::BeginTx(NYdb::NQuery::TTxSettings::SerializableRW()).CommitTx(),
              params).GetValueSync();
      },
      NYdb::NQuery::TRetryOperationSettings()
          .Idempotent(true)
  ));
}
```

userver

```cpp
#include <userver/ydb/io/supported_types.hpp>
#include <userver/ydb/table.hpp>

struct SeriesData final {
    std::uint64_t series_id;
    ydb::Utf8 title;
    ydb::Utf8 series_info;
    std::optional<ydb::Utf8> comment;
};

void UpsertSeries(ydb::TableClient& client) {
    auto builder = client.GetBuilder();
    builder.Add(
        "$seriesData",
        std::vector<SeriesData>{
            {
                .series_id = 1,
                .title = ydb::Utf8{"IT Crowd"},
                .series_info = ydb::Utf8{
                    "The IT Crowd is a British sitcom produced by Channel 4, written by Graham Linehan, produ
ced by "
                    "Ash Atalla and starring Chris O'Dowd, Richard Ayoade, Katherine Parkinson, and Matt Berr
y."
                },
                .comment = std::nullopt,
            },
            {
                .series_id = 2,
                .title = ydb::Utf8{"Silicon Valley"},
                .series_info = ydb::Utf8{
                    "Silicon Valley is an American comedy television series created by Mike Judge, John Altsc
huler and "
                    "Dave Krinsky. The series focuses on five young men who founded a startup company in Sili
con Valley."
                },
                .comment = ydb::Utf8{"lorem ipsum"},
            },
        }
    );

    client.ExecuteQuery(
        ydb::OperationSettings{
            .tx_mode = ydb::TransactionMode::kSerializableRW,
            .is_idempotent = true,
        },
        ydb::Query{R"(
            DECLARE $seriesData AS List<Struct<
                series_id: Uint64,
                title: Utf8,
                series_info: Utf8,

          types.StructFieldValue("series_id", types.Uint64Value(1)),
          types.StructFieldValue("title", types.TextValue("IT Crowd")),
          types.StructFieldValue("series_info", types.TextValue(
            "The IT Crowd is a British sitcom produced by Channel 4, written by Graham Linehan, produced by
"+
            "Ash Atalla and starring Chris O'Dowd, Richard Ayoade, Katherine Parkinson, and Matt Berry.",
          )),
          types.StructFieldValue("comment", types.NullValue(types.TypeText)),
        ),
        types.StructValue(
          types.StructFieldValue("series_id", types.Uint64Value(2)),
          types.StructFieldValue("title", types.TextValue("Silicon Valley")),
          types.StructFieldValue("series_info", types.TextValue(
            "Silicon Valley is an American comedy television series created by Mike Judge, John Altschuler an
d "+
            "Dave Krinsky. The series focuses on five young men who founded a startup company in Silicon Vall
ey.",
          )),
          types.StructFieldValue("comment", types.TextValue("lorem ipsum")),
        ),
      )),
    ); err != nil {
      return err
    }
    return nil
  }, retry.WithDoTxRetryOptions(retry.WithIdempotent(true)))
  if err != nil {
    fmt.Printf("unexpected error: %v", err)
  }
}
```

Java

Native SDK

Use `SessionRetryContext` and `TableSession.executeDataQuery` with the `$seriesData` parameter of type `List<Struct<...>>`. Values for `AS_TABLE($seriesData)` are collected in the same way as row structures in the batch upsert example.

```
SessionRetryContext retryCtx = SessionRetryContext.create(tableClient).build();

String yql = """
        PRAGMA TablePathPrefix("/local");
        DECLARE $seriesData AS List<Struct<
            series_id: Uint64,
            title: Utf8,
            series_info: Utf8,
            comment: Optional<Utf8>
        >>;
        UPSERT INTO series
        SELECT series_id, title, series_info, comment FROM AS_TABLE($seriesData);
        """;

Params params = Params.of("$seriesData", seriesDataListValue);

retryCtx.supplyResult(session -> session.executeDataQuery(yql, TxControl.serializableRw(), params))
        .join();
```

JDBC

```
try (Connection conn = DriverManager.getConnection("jdbc:ydb:grpc://localhost:2136/local");
     PreparedStatement ps = conn.prepareStatement(
             """
             REPLACE INTO series (series_id, title, series_info, comment)
             SELECT series_id, title, series_info, comment FROM AS_TABLE($seriesData);
             """
     )) {
    // The $seriesData parameter is set according to the query type (see the JDBC driver documentation)
}
```

In Spring Boot, Hibernate, JOOQ, and other frameworks on top of JDBC, the driver also tries to optimize **large** sequences of inserts and updates: when necessary, **UPSERT**, `INSERT`, `UPDATE`, `DELETE` are automatically **grouped into batches** on the driver side (including large batches from ORM).

Python

Native SDK

To upsert data, use `QuerySessionPool` and the `execute_with_retries` method with a parameterized YQL query. The query operates on the container type `List<Struct<...>>`, which allows passing multiple rows in a single call.

```
import os
import ydb

with ydb.Driver(
    connection_string=os.environ["YDB_CONNECTION_STRING"],
    credentials=ydb.credentials_from_env_variables(),
) as driver:
    driver.wait(timeout=5)
    pool = ydb.QuerySessionPool(driver)

    series_struct_type = ydb.StructType()
    series_struct_type.add_member("series_id", ydb.PrimitiveType.Uint64)
    series_struct_type.add_member("title", ydb.PrimitiveType.Utf8)
    series_struct_type.add_member("series_info", ydb.PrimitiveType.Utf8)
    series_struct_type.add_member("comment", ydb.OptionalType(ydb.PrimitiveType.Utf8))

    series_data = [
        {
            "series_id": 1,
            "title": "IT Crowd",
            "series_info": "The IT Crowd is a British sitcom...",
            "comment": None,
        },
        {
            "series_id": 2,
            "title": "Silicon Valley",
            "series_info": "Silicon Valley is an American comedy...",
            "comment": "lorem ipsum",
        },
    ]

    pool.execute_with_retries(
        """
        DECLARE $seriesData AS List<Struct<
            series_id: Uint64,
            title: Utf8,
            series_info: Utf8,
            comment: Optional<Utf8>
        >>;

        UPSERT INTO series
        (
            series_id,
            title,
            series_info,
            comment
        )
        SELECT
            series_id,
            title,
            series_info,
            comment
        FROM AS_TABLE($seriesData);
        """,
        {"$seriesData": (series_data, ydb.ListType(series_struct_type))},
        retry_settings=ydb.RetrySettings(idempotent=True),
    )
```

Native SDK (Asyncio)

```
import os
import ydb
import asyncio

async def ydb_init():
    async with ydb.aio.Driver(
        connection_string=os.environ["YDB_CONNECTION_STRING"],
        credentials=ydb.credentials_from_env_variables(),
    ) as driver:
        await driver.wait()
        pool = ydb.aio.QuerySessionPool(driver)

        series_struct_type = ydb.StructType()
        series_struct_type.add_member("series_id", ydb.PrimitiveType.Uint64)
        series_struct_type.add_member("title", ydb.PrimitiveType.Utf8)
        series_struct_type.add_member("series_info", ydb.PrimitiveType.Utf8)
        series_struct_type.add_member("comment", ydb.OptionalType(ydb.PrimitiveType.Utf8))

        series_data = [
            {"series_id": 1, "title": "IT Crowd", "series_info": "The IT Crowd is a British sitcom...", "comm
ent": None},
            {"series_id": 2, "title": "Silicon Valley", "series_info": "Silicon Valley is an American comed
y...", "comment": "lorem ipsum"},
        ]

        await pool.execute_with_retries(
            """
            DECLARE $seriesData AS List<Struct<
                series_id: Uint64,
                title: Utf8,
                series_info: Utf8,
                comment: Optional<Utf8>
            >>;

            UPSERT INTO series (series_id, title, series_info, comment)
            SELECT series_id, title, series_info, comment FROM AS_TABLE($seriesData);
            """,
            {"$seriesData": (series_data, ydb.ListType(series_struct_type))},
            retry_settings=ydb.RetrySettings(idempotent=True),
        )

asyncio.run(ydb_init())
```

SQLAlchemy

When using YDB via SQLAlchemy, the `ydb_sqlalchemy.upsert` function is used to insert data, which generates an `UPSERT INTO` query based on the table and the passed values. You can insert either a single row or multiple rows in one call:

```
import os
import sqlalchemy as sa
from sqlalchemy import Column, Integer, MetaData, String, Table
import ydb_sqlalchemy as ydb_sa

engine = sa.create_engine(os.environ["YDB_SQLALCHEMY_URL"])

series = Table(
    "series",
    MetaData(),
    Column("series_id", Integer, primary_key=True),
    Column("title", String),
    Column("series_info", String),
    Column("comment", String, nullable=True),
)

with engine.connect() as connection:
    stmt = ydb_sa.upsert(series).values(
        [
            {
                "series_id": 1,
                "title": "IT Crowd",
                "series_info": "The IT Crowd is a British sitcom...",
                "comment": None,
            },
            {
                "series_id": 2,
                "title": "Silicon Valley",
                "series_info": "Silicon Valley is an American comedy...",
                "comment": "lorem ipsum",
            },
        ]
    )
    connection.execute(stmt)
    connection.commit()
```

C#

```
using Ydb.Sdk.Ado;
using Ydb.Sdk.Ado.YdbType;

await using var dataSource = new YdbDataSource("Host=localhost;Port=2136;Database=/local");
await using var connection = await dataSource.OpenRetryableConnectionAsync();

var seriesData = new List<YdbStruct>
{
    new()
    {
        { "series_id", 1UL, YdbDbType.Uint64 },
        { "title", "IT Crowd", YdbDbType.Text },
        { "series_info", "The IT Crowd is a British sitcom produced by Channel 4.", YdbDbType.Text },
        { "comment", null, YdbDbType.Text },
    },
    new()
    {
        { "series_id", 2UL, YdbDbType.Uint64 },
        { "title", "Silicon Valley", YdbDbType.Text },
        { "series_info", "Silicon Valley is an American comedy television series.", YdbDbType.Text },
        { "comment", "lorem ipsum", YdbDbType.Text },
    },
};

var command = new YdbCommand("UPSERT INTO series SELECT * FROM AS_TABLE($series_data)", connection);
command.Parameters.Add(new YdbParameter("$series_data", seriesData));

await command.ExecuteNonQueryAsync();
```

JavaScript

```
import { Driver } from '@ydbjs/core'
import { query } from '@ydbjs/query'

const driver = new Driver('grpc://localhost:2136/local')
await driver.ready()

const users = [
  { id: 1, name: 'Alice' },
  { id: 2, name: 'Bob' },
]

const sql = query(driver)
await sql`UPSERT INTO users SELECT * FROM AS_TABLE(${users})`
```

Rust

```rust
use ydb::{
    ydb_params, ydb_struct, AccessTokenCredentials, ClientBuilder, Value, YdbResult,
};

fn series_row(
    series_id: u64,
    title: &str,
    series_info: &str,
    comment: Option<&str>,
) -> YdbResult<Value> {
    let comment_val = match comment {
        None => Value::optional_from(Value::Text(String::new()), None)?,
        Some(s) => Value::optional_from(
            Value::Text(String::new()),
            Some(Value::Text(s.into())),
        )?,
    };
    Ok(ydb_struct!(
        "series_id" => series_id,
        "title" => title,
        "series_info" => series_info,
        "comment" => comment_val,
    ))
}

#[tokio::main]
async fn main() -> YdbResult<()> {
    let client = ClientBuilder::new_from_connection_string(
        "grpc://localhost:2136?database=local",
    )?
    .with_credentials(AccessTokenCredentials::from("..."))
    .client()?;

    client.wait().await?;

    let example = series_row(0, "", "", None)?;
    let series_data = Value::list_from(
        example,
        vec![
            series_row(
                1,

                "The IT Crowd is a British sitcom...",
                None,
            )?,
            series_row(
                2,
                "Silicon Valley",
                "Silicon Valley is an American comedy...",
                Some("lorem ipsum"),
            )?,
        ],
    )?;

    client
        .query_client()
        .exec(
            r#"
            PRAGMA TablePathPrefix("/local");
            UPSERT INTO series
            (
                series_id,
                title,
                series_info,
                comment
            )
            SELECT
                series_id,
                title,
                series_info,
                comment
            FROM AS_TABLE($seriesData);
            "#,
        )
        .params(ydb_params!("$seriesData" => series_data))
        .await?;

    Ok(())
}
```

PHP

```php
<?php

use YdbPlatform\Ydb\Session;
use YdbPlatform\Ydb\Ydb;

$ydb = new Ydb($config);

$yql = <<<'EOS'
PRAGMA TablePathPrefix("/local");
DECLARE $seriesData AS List<Struct<
    series_id: Uint64,
    title: Utf8,
    series_info: Utf8,
    comment: Optional<Utf8>
>>;

UPSERT INTO series
(
    series_id,
    title,
    series_info,
    comment
)
SELECT
    series_id,
    title,
    series_info,
    comment
FROM AS_TABLE($seriesData);
EOS;

$seriesData = [
    [
        'series_id' => 1,
        'title' => 'IT Crowd',
        'series_info' => 'The IT Crowd is a British sitcom...',
        'comment' => null,
    ],
    [
        'series_id' => 2,
        'title' => 'Silicon Valley',
        'series_info' => 'Silicon Valley is an American comedy...',
        'comment' => 'lorem ipsum',
    ],
];

$ydb->table()->retryTransaction(
    function (Session $session) use ($yql, $seriesData) {
        return $session->prepare($yql)->execute([
            'seriesData' => $seriesData,
        ]);
    },
    true
);
```

Bulk upsert of data

YDB supports bulk insert of many rows without atomicity guarantees. The write is split into several independent transactions, each touching a single partition, with parallel execution. This makes the approach more efficient than plain YQL. On success, the `BulkUpsert` method guarantees that all data passed in the request is inserted.

> **Warning**
>
> When you load data to column-oriented tables using `BulkUpsert`, you must provide values for **all** columns, even `NULL` values.

Below are examples of using the YDB SDK built-in tools for bulk insert:

Go

Native SDK

Bulk upsert with native YDB data

```
package main

import (
  "context"
  "fmt"
  "os"
  "time"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/table"
  "github.com/ydb-platform/ydb-go-sdk/v3/table/types"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithAccessTokenCredentials(os.Getenv("YDB_TOKEN")),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  type logMessage struct {
    App       string
    Host      string
    Timestamp time.Time
    HTTPCode  uint32
    Message   string
  }
  // prepare native go data
  const batchSize = 10000
  logs := make([]logMessage, 0, batchSize)
  for i := 0; i < batchSize; i++ {
    message := logMessage{
      App:       fmt.Sprintf("App_%d", i/256),
      Host:      fmt.Sprintf("192.168.0.%d", i%256),
      Timestamp: time.Now().Add(time.Millisecond * time.Duration(i%1000)),
      HTTPCode:  200,
    }
    if i%2 == 0 {
      message.Message = "GET / HTTP/1.1"
    } else {
      message.Message = "GET /images/logo.png HTTP/1.1"
    }
    logs = append(logs, message)
  }
  // execute bulk upsert with native ydb data
  err = db.Table().Do( // Do retry operation on errors with best effort
    ctx, // context manage exiting from Do
    func(ctx context.Context, s table.Session) (err error) { // retry operation
      rows := make([]types.Value, 0, len(logs))
      for _, msg := range logs {
        rows = append(rows, types.StructValue(
          types.StructFieldValue("App", types.UTF8Value(msg.App)),
          types.StructFieldValue("Host", types.UTF8Value(msg.Host)),
          types.StructFieldValue("Timestamp", types.TimestampValueFromTime(msg.Timestamp)),
          types.StructFieldValue("HTTPCode", types.Uint32Value(msg.HTTPCode)),
          types.StructFieldValue("Message", types.UTF8Value(msg.Message)),
        ))
      }
      return s.BulkUpsert(ctx, "/local/bulk_upsert_example", types.ListValue(rows...))
    },
  )
  if err != nil {
    fmt.Printf("unexpected error: %v", err)
  }
}
```

Bulk upsert `CSV` data

```
package main

import (
  "context"
  "fmt"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/table"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()

  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithAccessTokenCredentials(os.Getenv("YDB_TOKEN")),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)

  csv := `skip row

id,val
42,"text42"
43,"text43"
44,hello
`

  err = db.Table().BulkUpsert(ctx, "/local/bulk_upsert_example", table.BulkUpsertDataCsv(
    []byte(csv),
    table.WithCsvHeader(),
    table.WithCsvSkipRows(2),
    table.WithCsvNullValue([]byte("hello")), // "hello" would be interpreted as NULL
  ))
  if err != nil {
    fmt.Printf("unexpected error: %v", err)
  }
}
```

Bulk upsert `Apache Arrow` data

In the following example, the arrow package is used to prepare the data.

```go
package main

import (
  "bytes"
  "context"
  "fmt"
  "os"

  "github.com/apache/arrow-go/v18/arrow"
  "github.com/apache/arrow-go/v18/arrow/array"
  "github.com/apache/arrow-go/v18/arrow/ipc"
  "github.com/apache/arrow-go/v18/arrow/memory"
  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/table"
)

func main() {
  ctx := context.Background()
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithAccessTokenCredentials(os.Getenv("YDB_TOKEN")),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx) // cleanup resources

  mem := memory.NewGoAllocator()

  schema := arrow.NewSchema([]arrow.Field{
    {Name: "id", Type: arrow.PrimitiveTypes.Int64},
    {Name: "val", Type: arrow.BinaryTypes.String},
  }, nil)

  b := array.NewRecordBuilder(mem, schema)
  defer b.Release()

  b.Field(0).(*array.Int64Builder).AppendValues(
    []int64{123, 234}, nil)

  b.Field(1).(*array.StringBuilder).AppendValues(
    []string{"data1", "data2"}, nil)

  rec := b.NewRecordBatch()
  defer rec.Release()

  schemaPayload := ipc.GetSchemaPayload(rec.Schema(), mem)
  defer schemaPayload.Release()

  dataPayload, err := ipc.GetRecordBatchPayload(rec)
  if err != nil {
    panic(err)
  }
  defer dataPayload.Release()

  var schemaBuf bytes.Buffer
  _, err = schemaPayload.WritePayload(&schemaBuf)
  if err != nil {
    panic(err)
  }

  var dataBuf bytes.Buffer
  _, err = dataPayload.WritePayload(&dataBuf)
  if err != nil {
    panic(err)
  }

  err = db.Table().BulkUpsert(ctx, "/local/bulk_upsert_example", table.BulkUpsertDataArrow(
    dataBuf.Bytes(),
    table.WithArrowSchema(schemaBuf.Bytes()), // schema is required
  ))
  if err != nil {
    fmt.Printf("unexpected error: %v", err)
  }
}
```

database/sql

The YDB `database/sql` driver does not support non-transactional bulk insert.
For bulk insert, use transactional insert.

Java

Native SDK

```
private static final String TABLE_NAME = "bulk_upsert";
private static final int BATCH_SIZE = 1000;

public static void main(String[] args) {
    String connectionString = args[0];

    try (GrpcTransport transport = GrpcTransport.forConnectionString(connectionString)
            .withAuthProvider(NopAuthProvider.INSTANCE) // use anonymous credentials
            .build()) {

        // For bulk upsert, the full table path needs to be specified
        String tablePath = transport.getDatabase() + "/" + TABLE_NAME;
        try (TableClient tableClient = TableClient.newClient(transport).build()) {
            SessionRetryContext retryCtx = SessionRetryContext.create(tableClient).build();
            execute(retryCtx, tablePath);
        }
    }
}

public static void execute(SessionRetryContext retryCtx, String tablePath) {
    // table description
    StructType structType = StructType.of(
        "app", PrimitiveType.Text,
        "timestamp", PrimitiveType.Timestamp,
        "host", PrimitiveType.Text,
        "http_code", PrimitiveType.Uint32,
        "message", PrimitiveType.Text
    );

    // generate batch of records
    List<Value<?>> list = new ArrayList<>(50);
    for (int i = 0; i < BATCH_SIZE; i += 1) {
        // add a new row as a struct value
        list.add(structType.newValue(
            "app", PrimitiveValue.newText("App_" + String.valueOf(i / 256)),
            "timestamp", PrimitiveValue.newTimestamp(Instant.now().plusSeconds(i)),
            "host", PrimitiveValue.newText("192.168.0." + i % 256),
            "http_code", PrimitiveValue.newUint32(i % 113 == 0 ? 404 : 200),
            "message", PrimitiveValue.newText(i % 3 == 0 ? "GET / HTTP/1.1" : "GET /images/logo.png HTTP/1.
1")
        ));
    }

    // Create list of structs
    ListValue rows = ListType.of(structType).newValue(list);
    // Do retry operation on errors with best effort
    retryCtx.supplyStatus(
        session -> session.executeBulkUpsert(tablePath, rows, new BulkUpsertSettings())
    ).join().expectSuccess("bulk upsert problem");
}
```

JDBC

```
private static final int BATCH_SIZE = 1000;

public static void main(String[] args) {
    String connectionUrl = args[0];

    try (Connection conn = DriverManager.getConnection(connectionUrl)) {
        try (PreparedStatement ps = conn.prepareStatement(
                "BULK UPSERT INTO bulk_upsert (app, timestamp, host, http_code, message) VALUES (?, ?, ?, ?,
?);"
        )) {
            for (int i = 0; i < BATCH_SIZE; i += 1) {
                ps.setString(1, "App_" + String.valueOf(i / 256));
                ps.setTimestamp(2, Timestamp.from(Instant.now().plusSeconds(i)));
                ps.setString(3, "192.168.0." + i % 256);
                ps.setLong(4, i % 113 == 0 ? 404 : 200);
                ps.setString(5, i % 3 == 0 ? "GET / HTTP/1.1" : "GET /images/logo.png HTTP/1.1");
                ps.addBatch();
            }

            ps.executeBatch();
        }
    } catch (SQLException e) {
        e.printStackTrace();
    }
}
```

In Spring Boot, Hibernate, JOOQ, and other ORM stacks on JDBC you can run native YQL (including from repositories and `@Query`). The driver tries to optimize large inserts; `UPDATE`, `INSERT`, `DELETE`, `UPSERT` through JDBC are batched on the driver side when appropriate.

Python

Native SDK

```python
import posixpath
import ydb

def bulk_upsert(driver: ydb.Driver, path: str):
    column_types = (
        ydb.BulkUpsertColumns()
        .add_column("id", ydb.PrimitiveType.Uint64)
        .add_column("val", ydb.OptionalType(ydb.PrimitiveType.Utf8))
    )
    rows = [
        {"id": 1, "val": "1"},
        {"id": 2, "val": "2"},
        {"id": 3, "val": "3"},
    ]
    driver.table_client.bulk_upsert(posixpath.join(path, "tablename"), rows, column_types)
```

Native SDK (Asyncio)

```python
import os
import posixpath
import ydb
import asyncio

async def bulk_upsert(driver: ydb.aio.Driver, path: str):
    column_types = (
        ydb.BulkUpsertColumns()
        .add_column("id", ydb.PrimitiveType.Uint64)
        .add_column("val", ydb.OptionalType(ydb.PrimitiveType.Utf8))
    )
    rows = [
        {"id": 1, "val": "1"},
        {"id": 2, "val": "2"},
        {"id": 3, "val": "3"},
    ]
    await driver.table_client.bulk_upsert(
        posixpath.join(path, "tablename"), rows, column_types
    )

async def main():
    async with ydb.aio.Driver(
        connection_string=os.environ["YDB_CONNECTION_STRING"],
        credentials=ydb.credentials_from_env_variables(),
    ) as driver:
        await driver.wait()
        await bulk_upsert(driver, "/local")

asyncio.run(main())
```

SQLAlchemy

```python
import os
import sqlalchemy as sa
import ydb

engine = sa.create_engine(os.environ["YDB_SQLALCHEMY_URL"])
with engine.connect() as connection:
    dbapi_conn = connection.connection

    column_types = (
          ydb.BulkUpsertColumns()
          .add_column("id", ydb.PrimitiveType.Uint64)
          .add_column("val", ydb.OptionalType(ydb.PrimitiveType.Utf8))
      )
    rows = [
        {"id": 1, "val": "1"},
        {"id": 2, "val": "2"},
        {"id": 3, "val": "3"},
    ]

    dbapi_conn.bulk_upsert("tablename", rows, column_types)
```

C#

This functionality is not currently supported.

JavaScript

This functionality is not currently supported.

Rust

```rust
use ydb::{ydb_struct, AccessTokenCredentials, ClientBuilder, Value, YdbResult};

#[tokio::main]
async fn main() -> YdbResult<()> {
    let client = ClientBuilder::new_from_connection_string(
        "grpc://localhost:2136?database=local",
    )?
    .with_credentials(AccessTokenCredentials::from("..."))
    .client()?;

    client.wait().await?;

    let rows: Vec<Value> = vec![
        ydb_struct!(
            "id" => 1_u64,
            "val" => Value::Text("1".into()),
        ),
        ydb_struct!(
            "id" => 2_u64,
            "val" => Value::Text("2".into()),
        ),
        ydb_struct!(
            "id" => 3_u64,
            "val" => Value::Text("3".into()),
        ),
    ];

    client
        .table_client()
        .retry_execute_bulk_upsert("/local/tablename".into(), rows)
        .await?;

    Ok(())
}
```

PHP

```php
<?php

use YdbPlatform\Ydb\Ydb;

$ydb = new Ydb($config);

$rows = [
    ['id' => 1, 'val' => '1'],
    ['id' => 2, 'val' => '2'],
    ['id' => 3, 'val' => '3'],
];

$ydb->table()->bulkUpsert('tablename', $rows, [
    'id'  => 'UINT64',
    'val' => 'UTF8',
]);
```

Setting up the transaction execution mode

To run your queries, first you need to specify the transaction execution mode in the YDB SDK.

Below are code examples showing the YDB SDK built-in tools to create an object for the *transaction execution mode*.

ImplicitTx

ImplicitTx mode allows executing a single query without explicit transaction control. The query is executed in its own implicit transaction that automatically commits if successful.

Go

Native SDK

```
package main

import (
  "context"
  "fmt"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/query"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithAccessTokenCredentials(os.Getenv("YDB_TOKEN")),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  row, err := db.Query().QueryRow(ctx, "SELECT 1",
    query.WithTxControl(query.ImplicitTxControl()),
  )
  if err != nil {
    fmt.Printf("unexpected error: %v", err)
  }
  // work with row
  _ = row
}
```

database/sql

```
package main

import (
  "context"
  "database/sql"
  "fmt"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithAccessTokenCredentials(os.Getenv("YDB_TOKEN")),
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)

  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }
  defer connector.Close()

  db := sql.OpenDB(connector)
  defer db.Close()

  // ImplicitTx — query without an explicit transaction (auto-commit)
  row := db.QueryRowContext(ctx, "SELECT 1")
  var result int
  if err := row.Scan(&result); err != nil {
    fmt.Printf("unexpected error: %v", err)
  }
}
```

Java

Native SDK

```
import tech.ydb.query.QueryClient;
import tech.ydb.query.tools.QueryReader;
import tech.ydb.query.tools.SessionRetryContext;

// ...
try (QueryClient queryClient = QueryClient.newClient(transport).build()) {
    SessionRetryContext retryCtx = SessionRetryContext.create(queryClient).build();
    QueryReader reader = retryCtx.supplyResult(
        session -> QueryReader.readFrom(session.createQuery("SELECT 1", TxMode.NONE))
    );
    // work with reader
}
```

JDBC

On the JDBC side, implicit mode corresponds to auto-commit (`Connection.setAutoCommit(true)` by default): each standalone statement runs as its own transaction and commits automatically. With `setAutoCommit(false)`, boundaries are defined by explicit `commit` / `rollback`.

In the **current** YDB JDBC driver, for **standalone read** calls, **snapshot** mode is used when **`setReadOnly(true)`** is set on the `Connection`. **Write** queries use **Serializable Read/Write** (the connection must not be read-only).

In **Spring**, the **`@Transactional(readOnly = true)`** attribute triggers `Connection.setReadOnly(true)` when the transaction starts, so snapshot is selected automatically for read-only flows. Hibernate, JOOQ, and other JDBC wrappers use the same connection — set read-only the same way (or via framework transaction settings if they propagate it to `Connection`).

Python

Native SDK

```
import ydb

def execute_query(pool: ydb.QuerySessionPool):
    pool.execute_with_retries("SELECT 1")
```

Native SDK (Asyncio)

```
import ydb

async def execute_query(pool: ydb.aio.QuerySessionPool):
    await pool.execute_with_retries("SELECT 1")
```

SQLAlchemy

```
import sqlalchemy as sa
from ydb_sqlalchemy import IsolationLevel

engine = sa.create_engine("yql+ydb://localhost:2136/local")
with engine.connect().execution_options(isolation_level=IsolationLevel.AUTOCOMMIT) as connection:
    result = connection.execute(sa.text("SELECT 1"))
```

C++

```
auto result = session.ExecuteQuery(
    "SELECT 1",
    NYdb::NQuery::TTxControl::NoTx()
).GetValueSync();
```

C# (.NET)

ADO.NET

```
using Ydb.Sdk.Ado;

await using var connection = await dataSource.OpenRetryableConnectionAsync();

// Execute without explicit transaction (auto-commit)
await using var command = new YdbCommand(connection) { CommandText = "SELECT 1" };
await command.ExecuteNonQueryAsync();
```

Entity Framework

```
using Microsoft.EntityFrameworkCore;

await using var context = await dbContextFactory.CreateDbContextAsync();

// Entity Framework auto-commit mode (no explicit transaction)
var result = await context.SomeEntities.FirstOrDefaultAsync();
```

linq2db

```
using LinqToDB;
using LinqToDB.Data;

using var db = new DataConnection(
    new DataOptions().UseConnectionString(
        "YDB",
        "Host=localhost;Port=2136;Database=/local;UseTls=false"
    )
);

// linq2db auto-commit mode (no explicit transaction)
var result = db.GetTable<Employee>().FirstOrDefault(e => e.Id == 1);
```

```
using Ydb.Sdk.Services.Query;

// ImplicitTx - single query without explicit transaction
var response = await queryClient.Exec("SELECT 1");
```

JavaScript

```
import { sql } from '@ydbjs/query';

// ...

// ImplicitTx - single query without explicit transaction
const result = await sql`SELECT 1`;
```

Rust

```
let mut qc = client.query_client();
// ImplicitTx is the default for QueryClient methods that execute a single SQL statement:
// the server picks isolation from SQL (SELECT → snapshot RO, DML → serializable RW).
let mut row = qc.query_row("SELECT 1 AS one").await?;
```

PHP

```
<?php

use YdbPlatform\Ydb\Ydb;

$config = [
    // YDB config
];

$ydb = new Ydb($config);
$result = $ydb->table()->query('SELECT 1;');
```

Serializable

Go

Native SDK

```go
package main

import (
  "context"
  "fmt"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/query"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithAccessTokenCredentials(os.Getenv("YDB_TOKEN")),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  row, err := db.Query().QueryRow(ctx, "SELECT 1",
    query.WithTxControl(query.SerializableReadWriteTxControl(query.CommitTx())),
  )
  if err != nil {
    fmt.Printf("unexpected error: %v", err)
  }
  // work with row
  _ = row
}
```

database/sql

```go
package main

import (
  "context"
  "database/sql"
  "fmt"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/retry"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithAccessTokenCredentials(os.Getenv("YDB_TOKEN")),
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)

  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }
  defer connector.Close()

  db := sql.OpenDB(connector)
  defer db.Close()

  err = retry.DoTx(ctx, db,
    func(ctx context.Context, tx *sql.Tx) error {
      row := tx.QueryRowContext(ctx, "SELECT 1")
      var result int
      return row.Scan(&result)
    },
    retry.WithIdempotent(true),
    // Serializable Read-Write mode is used by default for transactions.
    // Alternatively, set it explicitly as shown below.
    retry.WithTxOptions(&sql.TxOptions{
      Isolation: sql.LevelSerializable,
      ReadOnly:  false,
    }),
  )
  if err != nil {
    fmt.Printf("unexpected error: %v", err)
  }
}
```

Java

Native SDK

```java
import tech.ydb.query.QueryClient;
import tech.ydb.query.TxMode;
import tech.ydb.query.tools.QueryReader;
import tech.ydb.query.tools.SessionRetryContext;

// ...
try (QueryClient queryClient = QueryClient.newClient(transport).build()) {
    SessionRetryContext retryCtx = SessionRetryContext.create(queryClient).build();
    QueryReader reader = retryCtx.supplyResult(
        session -> QueryReader.readFrom(session.createQuery("SELECT 1", TxMode.SERIALIZABLE_RW))
    );
    // work with reader
}
```

JDBC

For **standalone** JDBC calls, the **current** driver implementation uses **Serializable Read/Write** — including from Spring Boot, ORMs, and other JDBC wrappers. **Snapshot** for reads is enabled via `setReadOnly(true)` (see ImplicitTx). Auto-commit semantics and explicit transactions are described there as well.

Python

Native SDK

```python
import ydb

def execute_query(pool: ydb.QuerySessionPool):
    def callee(session: ydb.QuerySession):
        with session.transaction(ydb.QuerySerializableReadWrite()).execute(
            "SELECT 1",
            commit_tx=True,
        ) as result_sets:
            pass

    pool.retry_operation_sync(callee)
```

Native SDK (Asyncio)

```python
import ydb

async def execute_query(pool: ydb.aio.QuerySessionPool):
    async def callee(session):
        async with session.transaction(tx_mode=ydb.QuerySerializableReadWrite()) as tx:
            async with await tx.execute("SELECT 1", commit_tx=True) as result_sets:
                pass

    await pool.retry_operation_async(callee)
```

SQLAlchemy

```python
import sqlalchemy as sa
from ydb_sqlalchemy import IsolationLevel

engine = sa.create_engine("yql+ydb://localhost:2136/local")
with engine.connect().execution_options(isolation_level=IsolationLevel.SERIALIZABLE) as connection:
    result = connection.execute(sa.text("SELECT 1"))
```

C++

```cpp
auto settings = NYdb::NQuery::TTxSettings::SerializableRW();
auto result = session.ExecuteQuery(
    "SELECT 1",
    NYdb::NQuery::TTxControl::BeginTx(settings).CommitTx()
).GetValueSync();
```

C# (.NET)

ADO.NET

```
using Ydb.Sdk.Ado;

// Serializable Read-Write mode is used by default
await _ydbDataSource.ExecuteInTransactionAsync(async ydbConnection =>
    {
        var ydbCommand = ydbConnection.CreateCommand();
        ydbCommand.CommandText = """
                                 UPSERT INTO episodes (series_id, season_id, episode_id, title, air_date)
                                 VALUES (2, 5, 13, "Test Episode", Date("2018-08-27"))
                                 """;
        await ydbCommand.ExecuteNonQueryAsync();
        ydbCommand.CommandText = """
                                 INSERT INTO episodes(series_id, season_id, episode_id, title, air_date)
                                 VALUES
                                     (2, 5, 21, "Test 21", Date("2018-08-27")),
                                     (2, 5, 22, "Test 22", Date("2018-08-27"))
                                 """;
        await ydbCommand.ExecuteNonQueryAsync();
    }
);
```

Entity Framework

```
var strategy = db.Database.CreateExecutionStrategy();

// Serializable Read-Write mode is used by default
strategy.ExecuteInTransaction(
    db,
    ctx =>
    {
        ctx.Users.AddRange(
            new User { Name = "Alex", Email = "alex@example.com" },
            new User { Name = "Kirill", Email = "kirill@example.com" }
        );

        ctx.SaveChanges();

        var users = ctx.Users.OrderBy(u => u.Id).ToList();
        Console.WriteLine("Users in database:");
        foreach (var user in users)
            Console.WriteLine($"- {user.Id}: {user.Name} ({user.Email})");
    },
    ctx => ctx.Users.Any(u => u.Email == "alex@example.com")
        && ctx.Users.Any(u => u.Email == "kirill@example.com")
);
```

linq2db

```
using LinqToDB;
using LinqToDB.Data;

// linq2db uses Serializable isolation by default
using var db = new DataConnection(
    new DataOptions().UseConnectionString(
        "YDB",
        "Host=localhost;Port=2136;Database=/local;UseTls=false"
    )
);

// Serializable Read-Write mode is used by default
await using var tr = await db.BeginTransactionAsync();

await db.InsertAsync(new Episode
{
    SeriesId = 2, SeasonId = 5, EpisodeId = 13, Title = "Test Episode", AirDate = new DateTime(2018, 08,
27)
});
await db.InsertAsync(new Episode
    { SeriesId = 2, SeasonId = 5, EpisodeId = 21, Title = "Test 21", AirDate = new DateTime(2018, 08, 27)
});
await db.InsertAsync(new Episode
    { SeriesId = 2, SeasonId = 5, EpisodeId = 22, Title = "Test 22", AirDate = new DateTime(2018, 08, 27)
});

await tr.CommitAsync();
```

```
using Ydb.Sdk.Services.Query;

// Serializable Read-Write mode is used by default
var response = await queryClient.Exec("SELECT 1");
```

JavaScript

```
import { sql } from '@ydbjs/query';

// ...

// Serializable Read-Write mode is used by default
await sql.begin({ idempotent: true }, async (tx) => {
    return await tx`SELECT 1`;
});

// Or explicitly specify transaction mode
await sql.begin({ isolation: 'serializableReadWrite', idempotent: true }, async (tx) => {
    return await tx`SELECT 1`;
});
```

Rust

```rust
use ydb::{QueryTransactionOptions, QueryTxMode};

let qc = client
    .query_client()
    .clone_with_transaction_options(
        QueryTransactionOptions::new().with_mode(QueryTxMode::SerializableReadWrite),
    );
qc.retry_transaction(async |tx| {
    tx.query_row("SELECT 1 AS one").await?;
    Ok(())
})
.await?;
```

PHP

```php
<?php

use YdbPlatform\Ydb\Ydb;

$config = [
    // YDB config
];

$ydb = new Ydb($config);
$result = $ydb->table()->retryTransaction(
  function (Session $session) {
      return $session->query('SELECT 1 AS value;');
  },
  true,
  null,
  ['tx_mode' => 'serializable_read_write']
);
```

    db,
    func(ctx context.Context, conn *sql.Conn) error {
      row := conn.QueryRowContext(ctx, "SELECT 1")
      var result int
      return row.Scan(&result)
    },
    retry.WithIdempotent(true),
  )
  if err != nil {
    fmt.Printf("unexpected error: %v", err)
  }
}
```

Java

Native SDK

```java
import tech.ydb.query.QueryClient;
import tech.ydb.query.TxMode;
import tech.ydb.query.tools.QueryReader;
import tech.ydb.query.tools.SessionRetryContext;

// ...
try (QueryClient queryClient = QueryClient.newClient(transport).build()) {
    SessionRetryContext retryCtx = SessionRetryContext.create(queryClient).build();
    QueryReader reader = retryCtx.supplyResult(
        session -> QueryReader.readFrom(session.createQuery("SELECT 1", TxMode.ONLINE_RO))
    );
    // work with reader
}
```

JDBC

Online Read-Only from the Query API is **not** configured separately for **standalone** JDBC calls. For **snapshot** reads, call `Connection.setReadOnly(true)` (in Spring — `@Transactional(readOnly = true)`). For writes, see ImplicitTx.

Python

Native SDK

```python
import ydb

def execute_query(pool: ydb.QuerySessionPool):
    def callee(session: ydb.QuerySession):
        with session.transaction(ydb.QueryOnlineReadOnly()).execute(
            "SELECT 1",
            commit_tx=True,
        ) as result_sets:
            pass

    pool.retry_operation_sync(callee)
```

Native SDK (Asyncio)

```python
import ydb

async def execute_query(pool: ydb.aio.QuerySessionPool):
    async def callee(session):
        async with session.transaction(tx_mode=ydb.QueryOnlineReadOnly()) as tx:
            async with await tx.execute("SELECT 1", commit_tx=True) as result_sets:
                pass

    await pool.retry_operation_async(callee)
```

SQLAlchemy

```python
import sqlalchemy as sa
from ydb_sqlalchemy import IsolationLevel

engine = sa.create_engine("yql+ydb://localhost:2136/local")
with engine.connect().execution_options(isolation_level=IsolationLevel.ONLINE_READONLY) as connection:
    result = connection.execute(sa.text("SELECT 1"))
```

C++

```cpp
auto settings = NYdb::NQuery::TTxSettings::OnlineRO();
auto result = session.ExecuteQuery(
    "SELECT 1",
    NYdb::NQuery::TTxControl::BeginTx(settings).CommitTx()
).GetValueSync();
```

C# (.NET)

ADO.NET

```csharp
using Ydb.Sdk.Ado;

await using var connection = await dataSource.OpenConnectionAsync();
await using var transaction = await connection.BeginTransactionAsync(TransactionMode.OnlineRo);
await using var command = new YdbCommand(connection) { CommandText = "SELECT 1" };
await using var reader = await command.ExecuteReaderAsync();
await transaction.CommitAsync();
```

Entity Framework

> Entity Framework does not support OnlineRo mode directly.
> Use ydb-dotnet-sdk or ADO.NET for this isolation level.

linq2db

> linq2db does not support OnlineRo mode directly.
> Use ydb-dotnet-sdk or ADO.NET for this isolation level.

```csharp
using Ydb.Sdk.Ado;
using Ydb.Sdk.Services.Query;

var response = await queryClient.ReadAllRows("SELECT 1", txMode: TransactionMode.OnlineRo);
```

JavaScript

```
import { sql } from '@ydbjs/query';

// ...

await sql.begin({ isolation: 'onlineReadOnly', idempotent: true }, async (tx) => {
    return await tx`SELECT 1`;
});
```

Rust

```
use ydb::QueryTxMode;

let mut qc = client.query_client();

// Online RO — consistent reads (allow_inconsistent_reads = false)
let mut row = qc
    .query_row("SELECT 1 AS one")
    .with_tx_mode(QueryTxMode::OnlineReadOnly)
    .await?;

// Online inconsistent RO — higher throughput (allow_inconsistent_reads = true)
let mut row = qc
    .query_row("SELECT 1 AS one")
    .with_tx_mode(QueryTxMode::OnlineReadOnlyInconsistent)
    .await?;
```

PHP

```
<?php

use YdbPlatform\Ydb\Ydb;

$config = [
    // YDB config
];

$ydb = new Ydb($config);
$result = $ydb->table()->retrySession(function (Session $session) {
  $query = $session->newQuery('SELECT 1 AS value;');
  $query->beginTx('online_read_only');
  return $query->execute();
}, true);
```

Stale Read-Only

Go

Native SDK

```
package main

import (
  "context"
  "fmt"

await using var connection = await dataSource.OpenConnectionAsync();
await using var transaction = await connection.BeginTransactionAsync(TransactionMode.StaleRo);
await using var command = new YdbCommand(connection) { CommandText = "SELECT 1", Transaction = transactio
n };
await using var reader = await command.ExecuteReaderAsync();
await transaction.CommitAsync();
```

Entity Framework

> Entity Framework does not support StaleRo mode directly.
> Use ydb-dotnet-sdk or ADO.NET for this isolation level.

linq2db

> linq2db does not support StaleRo mode directly.
> Use ydb-dotnet-sdk or ADO.NET for this isolation level.

```
using Ydb.Sdk.Ado;
using Ydb.Sdk.Services.Query;

var response = await queryClient.ReadAllRows("SELECT 1", txMode: TransactionMode.StaleRo);
```

JavaScript

```
import { sql } from '@ydbjs/query';

// ...

await sql.begin({ isolation: 'staleReadOnly', idempotent: true }, async (tx) => {
    return await tx`SELECT 1`;
});
```

Rust

```
use ydb::QueryTxMode;

let mut qc = client.query_client();
// Stale Read-Only is supported only for QueryClient methods that execute a single SQL statement (not for ret
ry_transaction).
let mut row = qc
    .query_row("SELECT 1 AS one")
    .with_tx_mode(QueryTxMode::StaleReadOnly)
    .await?;
```

PHP

```
<?php

use YdbPlatform\Ydb\Ydb;

$config = [
    // YDB config
];

$ydb = new Ydb($config);
$result = $ydb->table()->retrySession(function (Session $session) {
  $query = $session->newQuery('SELECT 1 AS value;');
  $query->beginTx('stale_read_only');
  return $query->execute();
}, true);
```

Snapshot Read-Only

Go

Native SDK

```
package main

import (
  "context"
  "fmt"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/query"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithAccessTokenCredentials(os.Getenv("YDB_TOKEN")),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  row, err := db.Query().QueryRow(ctx, "SELECT 1",
    query.WithTxControl(query.SnapshotReadOnlyTxControl()),
  )
  if err != nil {
    fmt.Printf("unexpected error: %v", err)
  }
  // work with row
  _ = row
}
```

database/sql

```
package main

import (
  "context"
  "database/sql"
  "fmt"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/retry"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithAccessTokenCredentials(os.Getenv("YDB_TOKEN")),
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)

  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }
  defer connector.Close()

  db := sql.OpenDB(connector)
  defer db.Close()

  // Snapshot Read-Only — consistent reads at a point in time
  err = retry.DoTx(ctx, db, func(ctx context.Context, tx *sql.Tx) error {
    row := tx.QueryRowContext(ctx, "SELECT 1")
    var result int
    return row.Scan(&result)
  }, retry.WithIdempotent(true), retry.WithTxOptions(&sql.TxOptions{
    Isolation: sql.LevelSnapshot,
    ReadOnly:  true,
  }))
  if err != nil {
    fmt.Printf("unexpected error: %v", err)
  }
}
```

Java

Native SDK

```
import tech.ydb.query.QueryClient;
import tech.ydb.query.TxMode;
import tech.ydb.query.tools.QueryReader;
import tech.ydb.query.tools.SessionRetryContext;

// ...
try (QueryClient queryClient = QueryClient.newClient(transport).build()) {
    SessionRetryContext retryCtx = SessionRetryContext.create(queryClient).build();
    QueryReader reader = retryCtx.supplyResult(
        session -> QueryReader.readFrom(session.createQuery("SELECT 1", TxMode.SNAPSHOT_RO))
    );
    // work with reader
}
```

JDBC

For **standalone read-only** JDBC calls, **snapshot** mode is enabled when `Connection.setReadOnly(true)` is set on the connection (in Spring, `@Transactional(readOnly = true)` propagates this to the driver when the transaction starts). See ImplicitTx for details.

Python

Native SDK

```
import ydb

def execute_query(pool: ydb.QuerySessionPool):
    def callee(session: ydb.QuerySession):
        with session.transaction(ydb.QuerySnapshotReadOnly()).execute(
            "SELECT 1",
            commit_tx=True,
        ) as result_sets:
            pass

    pool.retry_operation_sync(callee)
```

Native SDK (Asyncio)

```
import ydb

async def execute_query(pool: ydb.aio.QuerySessionPool):
    async def callee(session):
        async with session.transaction(tx_mode=ydb.QuerySnapshotReadOnly()) as tx:
            async with await tx.execute("SELECT 1", commit_tx=True) as result_sets:
                pass

    await pool.retry_operation_async(callee)
```

SQLAlchemy

```
import sqlalchemy as sa
from ydb_sqlalchemy import IsolationLevel

engine = sa.create_engine("yql+ydb://localhost:2136/local")
with engine.connect().execution_options(isolation_level=IsolationLevel.SNAPSHOT_READONLY) as connection:
    result = connection.execute(sa.text("SELECT 1"))
```

C++

```
auto settings = NYdb::NQuery::TTxSettings::SnapshotRO();
auto result = session.ExecuteQuery(
    "SELECT 1",
    NYdb::NQuery::TTxControl::BeginTx(settings).CommitTx()
).GetValueSync();
```

C# (.NET)

ADO.NET

```
using Ydb.Sdk.Ado;

await using var connection = await dataSource.OpenConnectionAsync();
await using var transaction = await connection.BeginTransactionAsync(TransactionMode.SnapshotRo);
await using var command = new YdbCommand(connection) { CommandText = "SELECT 1" };
await using var reader = await command.ExecuteReaderAsync();
await transaction.CommitAsync();
```

Entity Framework

Entity Framework does not support Snapshot Read-Only mode directly.
Use ydb-dotnet-sdk or ADO.NET for this isolation level.

linq2db

linq2db does not support Snapshot Read-Only mode directly.
Use ydb-dotnet-sdk or ADO.NET for this isolation level.

```
using Ydb.Sdk.Ado;
using Ydb.Sdk.Services.Query;

var response = await queryClient.ReadAllRows("SELECT 1", TransactionMode.SnapshotRo);
```

JavaScript

```
import { sql } from '@ydbjs/query';

// ...

await sql.begin({ isolation: 'snapshotReadOnly', idempotent: true }, async (tx) => {
    return await tx`SELECT 1`;
});
```

Rust

```rust
use ydb::{QueryTransactionOptions, QueryTxMode};

let mut qc = client.query_client();
qc.query_row("SELECT 1 AS one")
    .with_tx_mode(QueryTxMode::SnapshotReadOnly)
    .await?;

let qc = qc.clone_with_transaction_options(
    QueryTransactionOptions::new().with_mode(QueryTxMode::SnapshotReadOnly),
);
qc.retry_transaction(async |tx| {
    tx.query_row("SELECT 1 AS one").await?;
    Ok(())
})
.await?;
```

PHP

```php
<?php

use YdbPlatform\Ydb\Ydb;

$config = [
    // YDB config
];

$ydb = new Ydb($config);
$result = $ydb->table()->retryTransaction(
  function (Session $session) {
      return $session->query('SELECT 1 AS value;');
  },
  true,
  null,
  ['tx_mode' => 'snapshot_read_only']
);
```

Snapshot Read-Write

Go

Native SDK

```go
package main

import (
  "context"
  "fmt"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/query"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithAccessTokenCredentials(os.Getenv("YDB_TOKEN")),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  row, err := db.Query().QueryRow(ctx, "SELECT 1",
    query.WithTxControl(query.SnapshotReadWriteTxControl(query.CommitTx())),
  )
  if err != nil {
    fmt.Printf("unexpected error: %v", err)
  }
  // work with row
  _ = row
}
```

database/sql

```go
package main

import (
  "context"
  "database/sql"
  "fmt"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/retry"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithAccessTokenCredentials(os.Getenv("YDB_TOKEN")),
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)

  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }
  defer connector.Close()

  db := sql.OpenDB(connector)
  defer db.Close()

  // Snapshot Read-Write — consistent reads at a point in time with writes allowed
  err = retry.DoTx(ctx, db, func(ctx context.Context, tx *sql.Tx) error {
    row := tx.QueryRowContext(ctx, "SELECT 1")
    var result int
    return row.Scan(&result)
  }, retry.WithIdempotent(true), retry.WithTxOptions(&sql.TxOptions{
    Isolation: sql.LevelSnapshot,
    ReadOnly:  false,
  }))
  if err != nil {
    fmt.Printf("unexpected error: %v", err)
  }
}
```

Java

Native SDK

```java
import tech.ydb.query.QueryClient;
import tech.ydb.query.TxMode;
import tech.ydb.query.tools.QueryReader;
import tech.ydb.query.tools.SessionRetryContext;

// ...
try (QueryClient queryClient = QueryClient.newClient(transport).build()) {
    SessionRetryContext retryCtx = SessionRetryContext.create(queryClient).build();
    QueryReader reader = retryCtx.supplyResult(
        session -> QueryReader.readFrom(session.createQuery("SELECT 1", TxMode.SNAPSHOT_RW))
    );
    // work with reader
}
```

JDBC

Snapshot Read-Write from the Query API is **not** set separately for **standalone** JDBC calls; for **writes**, the **current** driver implementation uses **Serializable Read/Write** (see ImplicitTx and Serializable).

Python

Native SDK

```python
import ydb

def execute_query(pool: ydb.QuerySessionPool):
    def callee(session: ydb.QuerySession):
        with session.transaction(ydb.QuerySnapshotReadWrite()).execute(
            "SELECT 1",
            commit_tx=True,
        ) as result_sets:
            pass

    pool.retry_operation_sync(callee)
```

Native SDK (Asyncio)

```
import ydb

async def execute_query(pool: ydb.aio.QuerySessionPool):
    async def callee(session):
        async with session.transaction(tx_mode=ydb.QuerySnapshotReadWrite()) as tx:
            async with await tx.execute("SELECT 1", commit_tx=True) as result_sets:
                pass

    await pool.retry_operation_async(callee)
```

SQLAlchemy

```
import sqlalchemy as sa
from ydb_sqlalchemy import IsolationLevel

engine = sa.create_engine("yql+ydb://localhost:2136/local")
with engine.connect().execution_options(isolation_level=IsolationLevel.SNAPSHOT_READWRITE) as connection:
    result = connection.execute(sa.text("SELECT 1"))
```

C++

```
auto settings = NYdb::NQuery::TTxSettings::SnapshotRW();
auto result = session.ExecuteQuery(
    "SELECT 1",
    NYdb::NQuery::TTxControl::BeginTx(settings).CommitTx()
).GetValueSync();
```

C# (.NET)

ADO.NET

```
await _ydbDataSource.ExecuteInTransactionAsync(async ydbConnection =>
    {
        var ydbCommand = ydbConnection.CreateCommand();
        ydbCommand.CommandText = """
                                 UPSERT INTO episodes (series_id, season_id, episode_id, title, air_date)
                                 VALUES (2, 5, 13, "Test Episode", Date("2018-08-27"))
                                 """;
        await ydbCommand.ExecuteNonQueryAsync();
        ydbCommand.CommandText = """
                                 INSERT INTO episodes(series_id, season_id, episode_id, title, air_date)

                                     (2, 5, 22, "Test 22", Date("2018-08-27"))
                                 """;
        await ydbCommand.ExecuteNonQueryAsync();
    }, TransactionMode.SnapshotRw
);
```

EF

```
var strategy = db.Database.CreateExecutionStrategy();

strategy.Execute(() =>
    {
        using var ctx = new AppDbContext(options);
        using var tr = ctx.Database.BeginTransaction(IsolationLevel.Snapshot);

        ctx.Users.AddRange(
            new User { Name = "Alex", Email = "alex@example.com" },
            new User { Name = "Kirill", Email = "kirill@example.com" }
        );

        ctx.SaveChanges();

        var users = ctx.Users.OrderBy(u => u.Id).ToList();
        Console.WriteLine("Users in database:");
        foreach (var user in users)
            Console.WriteLine($"- {user.Id}: {user.Name} ({user.Email})");
      }
);
```

linq2db

```
await using var db = new MyYdb(BuildOptions());
await using var tr = await db.BeginTransactionAsync(IsolationLevel.Snapshot);

await db.InsertAsync(new Episode
{
    SeriesId = 2, SeasonId = 5, EpisodeId = 13, Title = "Test Episode", AirDate = new DateTime(2018, 08,
27)
});
await db.InsertAsync(new Episode
    { SeriesId = 2, SeasonId = 5, EpisodeId = 21, Title = "Test 21", AirDate = new DateTime(2018, 08, 27)
});
await db.InsertAsync(new Episode
    { SeriesId = 2, SeasonId = 5, EpisodeId = 22, Title = "Test 22", AirDate = new DateTime(2018, 08, 27)
});

await tr.CommitAsync();
```

```
using Ydb.Sdk.Ado;
using Ydb.Sdk.Services.Query;

var response = await queryClient.ReadAllRows("SELECT 1", TransactionMode.SnapshotRw);
```

JavaScript

```
import { sql } from '@ydbjs/query';

// ...

await sql.begin({ isolation: 'snapshotReadWrite', idempotent: true }, async (tx) => {
    return await tx`SELECT 1`;
});
```

Rust

```
use ydb::{QueryTransactionOptions, QueryTxMode};

let mut qc = client.query_client();
qc.query_row("SELECT 1 AS one")
    .with_tx_mode(QueryTxMode::SnapshotReadWrite)
    .await?;

let qc = qc.clone_with_transaction_options(
    QueryTransactionOptions::new().with_mode(QueryTxMode::SnapshotReadWrite),
);
qc.retry_transaction(async |tx| {
    tx.query_row("SELECT 1 AS one").await?;
    Ok(())
})
.await?;
```

PHP

Snapshot Read-Write mode is not supported in the PHP SDK.

Configuring Time to Live (TTL)

This section contains recipes for configuration of table's TTL with YDB SDK.

Enabling TTL for an existing table

In the example below, the items of the `mytable` table will be deleted an hour after the time set in the `created_at` column:

C++

```
session.AlterTable(
  "mytable",
  TAlterTableSettings()
    .BeginAlterTtlSettings()
      .Set("created_at", TDuration::Hours(1))
    .EndAlterTtlSettings()
);
```

Go

```
err := session.AlterTable(ctx, "mytable",
  options.WithSetTimeToLiveSettings(
    options.NewTTLSettings().ColumnDateType("created_at").ExpireAfter(time.Hour),
  ),
)
```

Python

```
session.alter_table('mytable', set_ttl_settings=ydb.TtlSettings().with_date_type_column('created_at', 3600))
```

JavaScript

This section is under development.

Java

```
AlterTableSettings settings = new AlterTableSettings()
        .setTableTtl(TableTtl.dateTimeColumn("created_at", 3600));

session.alterTable("mytable", settings).join().expectSuccess();
```

The example below shows how to use the `modified_at` column with a numeric type (`Uint32`) as a TTL column. The column value is interpreted as the number of seconds since the Unix epoch:

C++

```
session.AlterTable(
  "mytable",
  TAlterTableSettings()
    .BeginAlterTtlSettings()
      .Set("modified_at", TTtlSettings::EUnit::Seconds, TDuration::Hours(1))
    .EndAlterTtlSettings()
);
```

Go

```
err := session.AlterTable(ctx, "mytable",
  options.WithSetTimeToLiveSettings(
    options.NewTTLSettings().ColumnSeconds("modified_at").ExpireAfter(time.Hour),
  ),
)
```

Python

```
session.alter_table('mytable', set_ttl_settings=ydb.TtlSettings().with_value_since_unix_epoch('modified_at',
UNIT_SECONDS, 3600))
```

JavaScript

This section is under development.

Java

```
AlterTableSettings settings = new AlterTableSettings()
        .setTableTtl(TableTtl.valueSinceUnixEpoch(
                "modified_at",
                TableTtl.TtlUnit.SECONDS,
                3600
        ));

session.alterTable("mytable", settings).join().expectSuccess();
```

Enabling data eviction to S3-compatible external storage

> **Warning**
>
> Supported only for column-oriented tables. Support for row-oriented tables is currently under development.

To enable data eviction, an external data source object that describes a connection to the external storage is needed. Refer to YQL recipe for examples of creating an external data source.

In the following example, rows of the table `mytable` will be moved to the bucket described in the external data source `/Root/s3_cold_data` one hour after the time recorded in the column `created_at` and will be deleted after 24 hours:

C++

```
session.AlterTable(
    "mytable",
    TAlterTableSettings()
        .BeginAlterTtlSettings()
            .Set("created_at", {
                    TTtlTierSettings(TDuration::Hours(1), TTtlEvictToExternalStorageAction("/Root/s3_cold_dat
a")),
                    TTtlTierSettings(TDuration::Hours(24), TTtlDeleteAction("/Root/s3_cold_data"))
                })
        .EndAlterTtlSettings()
);
```

Java

This functionality is not currently supported.

Go

This functionality is not currently supported.

Python

This functionality is not currently supported.

JavaScript

This section is under development.

Enabling TTL for a newly created table

For a newly created table, you can pass TTL settings along with the table description:

C++

```
session.CreateTable(
  "mytable",
  TTableBuilder()
    .AddNullableColumn("id", EPrimitiveType::Uint64)
    .AddNullableColumn("expire_at", EPrimitiveType::Timestamp)
    .SetPrimaryKeyColumn("id")
    .SetTtlSettings("expire_at")
    .Build()
);
```

Go

```
err := session.CreateTable(ctx, "mytable",
  options.WithColumn("id", types.Optional(types.TypeUint64)),
  options.WithColumn("expire_at", types.Optional(types.TypeTimestamp)),
  options.WithTimeToLiveSettings(
    options.NewTTLSettings().ColumnDateType("expire_at"),
  ),
)
```

Python

```
session.create_table(
  'mytable',
  ydb.TableDescription()
    .with_column(ydb.Column('id', ydb.OptionalType(ydb.DataType.Uint64)))
    .with_column(ydb.Column('expire_at', ydb.OptionalType(ydb.DataType.Timestamp)))
    .with_primary_key('id')
    .with_ttl(ydb.TtlSettings().with_date_type_column('expire_at'))
)
```

JavaScript

This section is under development.

Java

```
TableDescription description = TableDescription.newBuilder()
        .addNullableColumn("id", PrimitiveType.Uint64)
        .addNullableColumn("expire_at", PrimitiveType.Timestamp)
        .setPrimaryKey("id")
        .setTtlSettings(TableTtl.dateTimeColumn("expire_at", 0))
        .build();

session.createTable("mytable", description).join().expectSuccess();
```

Disabling TTL

C++

```
session.AlterTable(
  "mytable",
  TAlterTableSettings()
    .BeginAlterTtlSettings()
      .Drop()
    .EndAlterTtlSettings()
);
```

Go

```
err := session.AlterTable(ctx, "mytable",
  options.WithDropTimeToLive(),
)
```

Python

```
session.alter_table('mytable', drop_ttl_settings=True)
```

JavaScript

This section is under development.

Java

```
AlterTableSettings settings = new AlterTableSettings()
        .setTableTtl(TableTtl.notSet());

session.alterTable("mytable", settings).join().expectSuccess();
```

Getting TTL settings

The current TTL settings can be obtained from the table description:

C++

```
auto desc = session.DescribeTable("mytable").GetValueSync().GetTableDescription();
auto ttl = desc.GetTtlSettings();
```

Go

```
desc, err := session.DescribeTable(ctx, "mytable")
if err != nil {
  // process error
}
ttl := desc.TimeToLiveSettings
```

Python

```
desc = session.describe_table('mytable')
ttl = desc.ttl_settings
```

JavaScript

This section is under development.

Java

```
TableTtl ttl = session.describeTable("mytable").join().getValue().getTableDescription().getTableTtl();
```

Vector search

This section contains code recipes in different programming languages for vector search tasks using the YDB SDK.

The following operations are covered in detail:

- Vector search
  - Connecting to YDB
  - Creating a table
  - Inserting vectors
  - Adding an index
  - Search by vector
  - Full example

This recipe creates a text store with the following structure:

Field	Description
`id`	Text identifier
`document`	Text
`embedding`	Vector representation of the text

The recipe assumes that `embedding` is already available.

Connecting to YDB

This section describes the minimum steps required to run queries in YDB.
For more information on connecting to YDB, see Initialize the driver.

C++

```
#include <ydb-cpp-sdk/client/query/client.h>

int main() {
    auto driverConfig = NYdb::CreateFromEnvironment(endpoint + "/?database=" + database);
    NYdb::TDriver driver(driverConfig);
    NYdb::NQuery::TQueryClient client(driver);

    // ...
}
```

Go

```
package main

import (
    "context"
    "os"

    "github.com/ydb-platform/ydb-go-sdk/v3"
)

func main() {
    ctx, cancel := context.WithCancel(context.Background())
    defer cancel()
    db, err := ydb.Open(ctx,
        os.Getenv("YDB_CONNECTION_STRING"),
    )
    if err != nil {
        panic(err)
    }
    defer db.Close(ctx)
}
```

Java

For queries, use `QueryClient` and `SessionRetryContext` (see driver initialization). Below is minimal setup and a client for the YQL Query Service:

```
import tech.ydb.core.grpc.GrpcTransport;
import tech.ydb.query.QueryClient;
import tech.ydb.query.tools.SessionRetryContext;

String connectionString = System.getenv().getOrDefault("YDB_CONNECTION_STRING", "grpc://localhost:2136/loca
l");

try (GrpcTransport transport = GrpcTransport.forConnectionString(connectionString).build();
    QueryClient queryClient = QueryClient.newClient(transport).build()) {

    SessionRetryContext retryCtx = SessionRetryContext.create(queryClient).build();
    // retryCtx.supplyResult(session -> QueryReader.readFrom(session.createQuery(...)))
}
```

Python

Native SDK

To run queries, create a `ydb.QuerySessionPool`.

```
import ydb

driver = ydb.Driver(
    endpoint=ydb_endpoint,
    database=ydb_database,
    credentials=ydb_credentials,
)
driver.wait(5, fail_fast=True)
pool = ydb.QuerySessionPool(driver)
```

Native SDK (Asyncio)

To run queries, create a `ydb.aio.QuerySessionPool`:

```
import asyncio
import ydb

async def main():
    async with ydb.aio.Driver(
        endpoint=ydb_endpoint,
        database=ydb_database,
        credentials=ydb_credentials,
    ) as driver:
        await driver.wait(5, fail_fast=True)
        pool = ydb.aio.QuerySessionPool(driver)
        # ... use pool ...

asyncio.run(main())
```

C#

Vector search examples for the .NET SDK are not available yet.

This functionality is not currently supported.

Track progress or vote for support: ydb-dotnet-sdk#657

JavaScript

```
import { Driver } from '@ydbjs/core'
import { query, unsafe, identifier } from '@ydbjs/query'

const driver = new Driver('grpc://localhost:2136/local')
await driver.ready()
const sql = query(driver)
```

Rust

```
use ydb::{ClientBuilder, YdbResult};

let client = ClientBuilder::new_from_connection_string(connection_string)?.client()?;
client.wait().await?;
let mut qc = client.query_client().clone_with_idempotent_operations(true);
```

PHP

Vector search examples for the PHP SDK are not available yet.

This functionality is not currently supported.

Track progress or vote for support: ydb-php-sdk#268

Creating a table

First, create a table to store documents and their vector representations.

Table structure:

Column name	Data type	Description
`id`	`Utf8`	Document identifier
`document`	`Utf8`	Document text
`embedding`	`String`	Vector representation of the document

> **Warning**
>
> The `String` type is used to store vectors. For details, see the exact vector search.

C++

```
void CreateVectorTable(NYdb::NQuery::TQueryClient& client, const std::string& tableName)
{
    std::string query = std::format(R"(
        CREATE TABLE IF NOT EXISTS `{}` (
            id Utf8,
            document Utf8,
            embedding String,
            PRIMARY KEY (id)
        ))", tableName);

    NYdb::NStatusHelpers::ThrowOnError(client.RetryQuerySync([&](NYdb::NQuery::TSession session) {
        return session.ExecuteQuery(query, NYdb::NQuery::TTxControl::NoTx()).ExtractValueSync();
    }));

    std::cout << "Vector table created: " << tableName << std::endl;
}
```

Go

```
func createVectorTable(ctx context.Context, db *ydb.Driver, tableName string) error {
    query := fmt.Sprintf(`
        CREATE TABLE IF NOT EXISTS %s (
            id Utf8,
            document Utf8,
            embedding String,
            PRIMARY KEY (id)
        );`, "`"+tableName+"`")

    return db.Query().Exec(ctx, query)
}
```

Java

```
import tech.ydb.common.transaction.TxMode;
import tech.ydb.query.tools.QueryReader;
import tech.ydb.query.tools.SessionRetryContext;
import tech.ydb.table.query.Params;

void createVectorTable(SessionRetryContext retryCtx, String tableName) {
    String query = String.format("""
            CREATE TABLE IF NOT EXISTS `%s` (
                id Utf8,
                document Utf8,
                embedding String,
                PRIMARY KEY (id)
            );""", tableName);

    retryCtx.supplyResult(session -> QueryReader.readFrom(
            session.createQuery(query, TxMode.NONE, Params.empty())
    )).join().getValue();

    System.out.println("Vector table created: " + tableName);
}
```

Python

Native SDK

```
import ydb

def create_vector_table(pool: ydb.QuerySessionPool, table_name: str) -> None:
    query = f"""
    CREATE TABLE IF NOT EXISTS `{table_name}` (
        id Utf8,
        document Utf8,
        embedding String,
        PRIMARY KEY (id)
    );"""

    pool.execute_with_retries(query)

    print(f"Vector table {table_name} created")
```

Native SDK (Asyncio)

```
import ydb

async def create_vector_table(pool: ydb.aio.QuerySessionPool, table_name: str) -> None:
    query = f"""
    CREATE TABLE IF NOT EXISTS `{table_name}` (
        id Utf8,
        document Utf8,
        embedding String,
        PRIMARY KEY (id)
    );"""

    await pool.execute_with_retries(query)

    print(f"Vector table {table_name} created")
```

C#

Vector search examples for the .NET SDK are not available yet.

This functionality is not currently supported.

Track progress or vote for support: ydb-dotnet-sdk#657

JavaScript

```
await sql`CREATE TABLE IF NOT EXISTS `table_name` (
    id Utf8,
    document Utf8,
    embedding String,
    PRIMARY KEY (id)
);`
```

Rust

```
qc.exec(format!(
    "CREATE TABLE IF NOT EXISTS `{table_name}` (
        id Utf8,
        document Utf8,
        embedding String,
        PRIMARY KEY (id)
    );", tableName,
))
.await?;
```

PHP

Vector search examples for the PHP SDK are not available yet.

This functionality is not currently supported.

Track progress or vote for support: ydb-php-sdk#268

Inserting vectors

To insert vectors, prepare and run a parameterized YQL query. Parameterization unifies inserts for different data.

The query uses the container type `List<Struct<...>>` (a list of structs), so you can pass any number of objects in one round trip.

In YDB tables, vectors are stored as serialized byte sequences. **Prefer performing this conversion on the client.** Alternatively, delegate conversion to the server using Knn UDF. Examples for both approaches follow.

C++

Recommended approach

Use `NYdb::NValueHelpers::Embedding` from C++ SDK v3.24.0 or later to serialize the vector.

```cpp
#include <ydb-cpp-sdk/client/value/embedding.h>

void InsertItemsAsBytes(
    NYdb::NQuery::TQueryClient& client,
    const std::string& tableName,
    const std::vector<TItem>& items)
{
    std::string query = std::format(R"(
        DECLARE $items AS List<Struct<
            id: Utf8,
            document: Utf8,
            embedding: Bytes
        >>;
        UPSERT INTO `{0}`
        (
            id,
            document,
            embedding
        )
        SELECT
            id,
            document,
            embedding,
        FROM AS_TABLE($items);
    )", tableName);

    NYdb::TParamsBuilder paramsBuilder;
    auto& valueBuilder = paramsBuilder.AddParam("$items");
    valueBuilder.BeginList();
    for (const auto& item : items) {
        valueBuilder.AddListItem();
        valueBuilder.BeginStruct();
        valueBuilder.AddMember("id").Utf8(item.Id);
        valueBuilder.AddMember("document").Utf8(item.Document);
        valueBuilder.AddMember("embedding", NYdb::NValueHelpers::Embedding(item.Embedding));
        valueBuilder.EndStruct();
    }
    valueBuilder.EndList();
    valueBuilder.Build();

    NYdb::NStatusHelpers::ThrowOnError(client.RetryQuerySync([params = paramsBuilder.Build(), &query](NYdb::NQuery::TSession session) {
        return session.ExecuteQuery(query, NYdb::NQuery::TTxControl::BeginTx(NYdb::NQuery::TTxSettings::SerializableRW()).CommitTx(), params).ExtractValueSync();
    }));

    std::cout << items.size() << " items inserted" << std::endl;
}
```

Alternative approach

> **Warning**
>
> Passing vectors as `List<Float>` and converting on the YQL side with `Knn::ToBinaryStringFloat` has lower performance than client-side byte array encoding.

```
void InsertItemsAsFloatList(
    NYdb::NQuery::TQueryClient& client,
    const std::string& tableName,
    const std::vector<TItem>& items)
{
    std::string query = std::format(R"(
        DECLARE $items AS List<Struct<
            id: Utf8,
            document: Utf8,
            embedding: List<Float>
        >>;

        UPSERT INTO `{}`
        (
            id,
            document,
            embedding
        )
        SELECT
            id,
            document,
            Untag(Knn::ToBinaryStringFloat(embedding), "FloatVector"),
        FROM AS_TABLE($items);
    )", tableName);

    NYdb::TParamsBuilder paramsBuilder;
    auto& valueBuilder = paramsBuilder.AddParam("$items");
    valueBuilder.BeginList();
    for (const auto& item : items) {
        valueBuilder.AddListItem();
        valueBuilder.BeginStruct();
        valueBuilder.AddMember("id").Utf8(item.Id);
        valueBuilder.AddMember("document").Utf8(item.Document);
        valueBuilder.AddMember("embedding").BeginList();
        for (const auto& value : item.Embedding) {
            valueBuilder.AddListItem().Float(value);
        }
        valueBuilder.EndList();
        valueBuilder.EndStruct();
    }
    valueBuilder.EndList();
    valueBuilder.Build();

    NYdb::NStatusHelpers::ThrowOnError(client.RetryQuerySync([params = paramsBuilder.Build(), &query](NYdb::N
Query::TSession session) {
        return session.ExecuteQuery(query, NYdb::NQuery::TTxControl::BeginTx(NYdb::NQuery::TTxSettings::Seria
lizableRW()).CommitTx(), params).ExtractValueSync();
    }));

    std::cout << items.size() << " items inserted" << std::endl;
}
```

Go

Use `sugar.Embedding` from Go SDK v3.153.0 or later to serialize the vector. Then execute a parameterized query:

```
import "github.com/ydb-platform/ydb-go-sdk/v3/sugar"

func insertItems(ctx context.Context, db *ydb.Driver, tableName string, items []Item) error {
    query := fmt.Sprintf(`
    DECLARE $items AS List<Struct<
        id: Utf8,
        document: Utf8,
        embedding: String
    >>;

    UPSERT INTO %s
    (id, document, embedding)
    SELECT id, document, embedding
    FROM AS_TABLE($items);
    `, "`"+tableName+"`")

    rows := make([]types.Value, 0, len(items))
    for _, item := range items {
    rows = append(rows, types.StructValue(
        types.StructFieldValue("id", types.UTF8Value(item.ID)),
        types.StructFieldValue("document", types.UTF8Value(item.Document)),
        types.StructFieldValue("embedding", sugar.Embedding(item.Embedding...)),
    ))
    }

    return db.Query().Exec(ctx, query,
    query.WithParameters(
        ydb.ParamsBuilder().Param("$items").BeginList().AddItems(rows...).EndList().Build(),
    ),
    )
}
```

Java

Recommended approach

```
import java.nio.ByteBuffer;
import java.nio.ByteOrder;
import java.util.ArrayList;
import java.util.List;

import tech.ydb.common.transaction.TxMode;
import tech.ydb.query.tools.QueryReader;
import tech.ydb.query.tools.SessionRetryContext;
import tech.ydb.table.query.Params;
import tech.ydb.table.values.ListType;
import tech.ydb.table.values.ListValue;
import tech.ydb.table.values.PrimitiveType;
import tech.ydb.table.values.PrimitiveValue;
import tech.ydb.table.values.StructType;
import tech.ydb.table.values.Value;

byte[] convertVectorToBytes(float[] vector) {
    ByteBuffer bb = ByteBuffer.allocate(vector.length * Float.BYTES + 1).order(ByteOrder.LITTLE_ENDIAN);
    for (float v : vector) {
        bb.putFloat(v);
    }
    bb.put((byte) 0x01);
    return bb.array();
}

void insertItemsAsBytes(SessionRetryContext retryCtx, String tableName, List<Item> items) {
    String query = String.format("""
            DECLARE $items AS List<Struct<
                id: Utf8,
                document: Utf8,
                embedding: String
            >>;

            UPSERT INTO `%s`
            (
                id,
                document,
                embedding
            )
            SELECT
                id,
                document,
                embedding,
            FROM AS_TABLE($items);""", tableName);

    StructType rowType = StructType.of(
            "id", PrimitiveType.Text,
            "document", PrimitiveType.Text,
            "embedding", PrimitiveType.Bytes
    );

    List<Value<?>> rows = new ArrayList<>(items.size());
    for (Item item : items) {
        rows.add(rowType.newValue(
                "id", PrimitiveValue.newText(item.id()),
                "document", PrimitiveValue.newText(item.document()),
                "embedding", PrimitiveValue.newBytes(convertVectorToBytes(item.embedding()))
        ));
    }

    ListValue itemsParam = ListType.of(rowType).newValue(rows);
    Params params = Params.of("$items", itemsParam);

    retryCtx.supplyResult(session -> QueryReader.readFrom(
            session.createQuery(query, TxMode.SERIALIZABLE_RW, params)
    )).join().getValue();

    System.out.println(items.size() + " items inserted");
}

// record Item(String id, String document, float[] embedding) {}
```

Note

The `ConvertVectorToBytes` function assumes a little-endian byte order on the client (e.g. x86_64). If a different byte order is used, adapt the `ConvertVectorToBytes` function accordingly.

Alternative approach

> **Warning**
>
> Passing vectors as `List<Float>` and converting on the YQL side with `Knn::ToBinaryStringFloat` has lower performance than client-side byte array encoding.

A variant that passes vector components as `List<Float>` and converts on the YQL side with `Knn::ToBinaryStringFloat` — same pattern as the alternative Python and C++ examples below:

```
import java.util.ArrayList;
import java.util.List;

import tech.ydb.common.transaction.TxMode;
import tech.ydb.query.tools.QueryReader;
import tech.ydb.query.tools.SessionRetryContext;
import tech.ydb.table.query.Params;
import tech.ydb.table.values.ListType;
import tech.ydb.table.values.ListValue;
import tech.ydb.table.values.PrimitiveType;
import tech.ydb.table.values.PrimitiveValue;
import tech.ydb.table.values.StructType;
import tech.ydb.table.values.Value;

void insertItemsAsFloatList(SessionRetryContext retryCtx, String tableName, List<Item> items) {
    String query = String.format("""
            DECLARE $items AS List<Struct<
                id: Utf8,
                document: Utf8,
                embedding: List<Float>
            >>;

            UPSERT INTO `%s`
            (
                id,
                document,
                embedding
            )
            SELECT
                id,
                document,
                Untag(Knn::ToBinaryStringFloat(embedding), "FloatVector"),
            FROM AS_TABLE($items);""", tableName);

    StructType rowType = StructType.of(
            "id", PrimitiveType.Text,
            "document", PrimitiveType.Text,
            "embedding", ListType.of(PrimitiveType.Float)
    );

    List<Value<?>> rows = new ArrayList<>(items.size());
    for (Item item : items) {
        Value<?>[] emb = new Value<?>[item.embedding().length];
        for (int i = 0; i < item.embedding().length; i++) {
            emb[i] = PrimitiveValue.newFloat(item.embedding()[i]);
        }
        ListValue embList = ListType.of(PrimitiveType.Float).newValueOwn(emb);
        rows.add(rowType.newValue(
                "id", PrimitiveValue.newText(item.id()),
                "document", PrimitiveValue.newText(item.document()),
                "embedding", embList
        ));
    }

    ListValue itemsParam = ListType.of(rowType).newValue(rows);
    Params params = Params.of("$items", itemsParam);

    retryCtx.supplyResult(session -> QueryReader.readFrom(
            session.createQuery(query, TxMode.SERIALIZABLE_RW, params)
    )).join().getValue();

    System.out.println(items.size() + " items inserted");
}

// record Item(String id, String document, float[] embedding) {}
```

Python

Recommended approach

Use `ydb.convert_floats_to_embedding_bytes` from Python SDK 3.33.1 or later to serialize vectors.

The method accepts an array of dictionaries `items`, where each dictionary contains `id` (identifier), `document` (text), and `embedding` (vector representation of the text, pre-serialized to a byte sequence).

The example below creates `items_struct_type = ydb.StructType()` with field types. To pass a list of such structs, wrap it in `ydb.ListType`: `ydb.ListType(items_struct_type)`.

Native SDK

```
import ydb

def insert_items_vector_as_bytes(
    pool: ydb.QuerySessionPool,
    table_name: str,
    items: list[dict],
) -> None:
    query = f"""
    DECLARE $items AS List<Struct<
        id: Utf8,
        document: Utf8,
        embedding: String
    >>;

    UPSERT INTO `{table_name}`
    (
        id,
        document,
        embedding
    )
    SELECT
        id,
        document,
        embedding,
    FROM AS_TABLE($items);
    """

    items_struct_type = ydb.StructType()
    items_struct_type.add_member("id", ydb.PrimitiveType.Utf8)
    items_struct_type.add_member("document", ydb.PrimitiveType.Utf8)
    items_struct_type.add_member("embedding", ydb.PrimitiveType.String)

    for item in items:
        item["embedding"] = ydb.convert_floats_to_embedding_bytes(item["embedding"])

    pool.execute_with_retries(
        query, {"$items": (items, ydb.ListType(items_struct_type))}
    )

    print(f"{len(items)} items inserted")
```

Native SDK (Asyncio)

```
import ydb

async def insert_items_vector_as_bytes(
    pool: ydb.aio.QuerySessionPool,
    table_name: str,
    items: list[dict],
) -> None:
    query = f"""
    DECLARE $items AS List<Struct<
        id: Utf8,
        document: Utf8,
        embedding: String
    >>;

    UPSERT INTO `{table_name}`
    (
        id,
        document,
        embedding
    )
    SELECT
        id,
        document,
        embedding,
    FROM AS_TABLE($items);
    """

    items_struct_type = ydb.StructType()
    items_struct_type.add_member("id", ydb.PrimitiveType.Utf8)
    items_struct_type.add_member("document", ydb.PrimitiveType.Utf8)
    items_struct_type.add_member("embedding", ydb.PrimitiveType.String)

    for item in items:
        item["embedding"] = ydb.convert_floats_to_embedding_bytes(item["embedding"])

    await pool.execute_with_retries(
        query, {"$items": (items, ydb.ListType(items_struct_type))}
    )

    print(f"{len(items)} items inserted")
```

Alternative approach

> **Warning**

JavaScript

Recommended approach

```
function convertVectorToBytes(vector) {
    const bytes = new Uint8Array(vector.length * 4 + 1);
    const view = new DataView(bytes.buffer);

    for (let i = 0; i < vector.length; i++) {
        view.setFloat32(i * 4, vector[i], true);
    }

    bytes[bytes.length - 1] = 0x01;
    return bytes;
}

const items = [
    {
    id: "first_doc",
    document: "My Document",
    embedding: convertVectorToBytes(new Float32Array([1.5, 2.5, 3.5]))
    }
]

await sql`
    UPSERT INTO `table_name` (id, document, embedding)
    SELECT id, document, embedding,
    FROM AS_TABLE($items);`
```

Alternative approach

> **Warning**
>
> Passing vectors as `List<Float>` and converting on the YQL side with `Knn::ToBinaryStringFloat` has lower performance than client-side byte array encoding.

```
const items = [
    {
    id: "first_doc",
    document: "My Document",
    embedding: new Float32Array([1.5, 2.5, 3.5])
    }
]

await sql`
    UPSERT INTO `table_name` (id, document, embedding)
    SELECT id, document, Untag(Knn::ToBinaryStringFloat(embedding), "FloatVector"),
    FROM AS_TABLE($items);`
```

Rust

```
use ydb::{Bytes, Value, ydb_struct};

fn convert_vector_to_bytes(vector: &[f32]) -> Bytes {
    let mut buf = Vec::with_capacity(vector.len() * 4 + 1);
    for v in vector {
        buf.extend_from_slice(&v.to_le_bytes());
    }
    buf.push(0x01);
    Bytes::from(buf)
}

let example = ydb_struct!(
    "id" => "",
    "document" => "",
    "embedding" => Bytes::default(),
);
let rows: Vec<Value> = items
    .iter()
    .map(|item| ydb_struct!(
        "id" => item.id,
        "document" => item.document,
        "embedding" => convert_vector_to_bytes(&item.embedding),
    ))
    .collect();
let list = Value::list_from(example, rows)?;

qc.exec(insert_query).param("$items", list).await?;
```

Adding an index

A vector index supports efficient approximate nearest-neighbor search. See vector indexes.

Adding an index takes two steps:

1. Create a temporary index.
2. Save the temporary index as permanent.

This works both for the first build and for rebuilds when an index already exists.

Available strategies:

- `similarity=cosine`;
- `similarity=inner_product`;
- `distance=cosine`;
- `distance=euclidean`;
- `distance=manhattan`.

Each strategy defines the function used for subsequent search. For details on these functions, see distance and similarity functions.

Parameters for the `vector_kmeans_tree` index type are described in the vector index.

C++

```
void AddIndex(
    NYdb::TDriver& driver,
    NYdb::NQuery::TQueryClient& client,
    const std::string& database,
    const std::string& tableName,
    const std::string& indexName,
    const std::string& strategy)
{
    std::string query = std::format(R"(
        ALTER TABLE `{0}`
        ADD INDEX {1}__temp
        GLOBAL USING vector_kmeans_tree
        ON (embedding)
        WITH (
            {2}
        );
    )", tableName, indexName, strategy);

    NYdb::NStatusHelpers::ThrowOnError(client.RetryQuerySync([&](NYdb::NQuery::TSession session) {
        return session.ExecuteQuery(query, NYdb::NQuery::TTxControl::NoTx()).ExtractValueSync();
    }));

    NYdb::NTable::TTableClient tableClient(driver);
    NYdb::NStatusHelpers::ThrowOnError(tableClient.RetryOperationSync([&](NYdb::NTable::TSession session) {
        return session.AlterTable(database + "/" + tableName, NYdb::NTable::TAlterTableSettings()
            .AppendRenameIndexes(NYdb::NTable::TRenameIndex{
                .SourceName_ = indexName + "__temp",
                .DestinationName_ = indexName,
                .ReplaceDestination_ = true
            })
        ).ExtractValueSync();
    }));

    std::cout << "Table index `" << indexName << "` for table `" << tableName << "` added" << std::endl;
}
```

Go

```
func addVectorIndex(
    ctx context.Context,
    db *ydb.Driver,
    tableName, indexName, strategy string
) error {
    tempIndexName := indexName + "__temp"
    query := fmt.Sprintf(`

Search by vector

Vector search uses a special YQL query where you define a similarity or distance function.
Supported values:

- `CosineSimilarity`;
- `InnerProductSimilarity`;
- `CosineDistance`;
- `ManhattanDistance`;
- `EuclideanDistance`.

For details, see distance and similarity functions.

You can specify the index name. If set, the query will include the `VIEW index_name` expression so that the vector index is used for search.

The method returns a list of dictionaries with the fields `id`, `document`, and `score` (a number indicating similarity or distance to the query vector).

C++

Recommended approach

```
#include <ydb-cpp-sdk/client/value/embedding.h>

std::vector<TResultItem> SearchItemsAsBytes(
    NYdb::NQuery::TQueryClient& client,
    const std::string& tableName,
    const std::vector<float>& embedding,
    const std::string& strategy,
    std::uint64_t limit,
    std::uint64_t topClusters = 10,
    const std::optional<std::string>& indexName = std::nullopt)
{
    std::string viewIndex = indexName ? "VIEW " + *indexName : "";
    std::string sortOrder = strategy.ends_with("Similarity") ? "DESC" : "ASC";

    std::string query = std::format(R"(
        PRAGMA ydb.KMeansTreeSearchTopSize = "{5}";
        DECLARE $embedding as Bytes;
        SELECT
            id,
            document,
            Knn::{2}(embedding, $embedding) as score
        FROM {0} {1}
        ORDER BY score {3}
        LIMIT {4};
    )", tableName, viewIndex, strategy, sortOrder, limit, topClusters);

    auto params = NYdb::TParamsBuilder()
        .AddParam("$embedding", NYdb::NValueHelpers::Embedding(embedding))
        .Build();

    std::vector<TResultItem> result;

    NYdb::NStatusHelpers::ThrowOnError(client.RetryQuerySync([params, &query, &result](NYdb::NQuery::TSession
session) {
        auto execResult = session.ExecuteQuery(query, NYdb::NQuery::TTxControl::BeginTx(NYdb::NQuery::TTxSett
ings::SerializableRW()).CommitTx(), params).ExtractValueSync();
        if (execResult.IsSuccess()) {
            auto parser = execResult.GetResultSetParser(0);
            while (parser.TryNextRow()) {
                result.push_back({
                    .Id = *parser.ColumnParser(0).GetOptionalUtf8(),
                    .Document = *parser.ColumnParser(1).GetOptionalUtf8(),
                    .Score = *parser.ColumnParser(2).GetOptionalFloat()
                });
            }
        }
        return execResult;
    }));

    return result;
}
```

Alternative approach

> **Warning**
>
> Passing vectors as `List<Float>` and converting on the YQL side with `Knn::ToBinaryStringFloat` has lower performance than client-side byte array encoding.

```cpp
std::vector<TResultItem> SearchItemsAsFloatList(
    NYdb::NQuery::TQueryClient& client,
    const std::string& tableName,
    const std::vector<float>& embedding,
    const std::string& strategy,
    std::uint64_t limit,
    std::uint64_t topClusters = 10,
    const std::optional<std::string>& indexName = std::nullopt)
{
    std::string viewIndex = indexName ? "VIEW " + *indexName : "";
    std::string sortOrder = strategy.ends_with("Similarity") ? "DESC" : "ASC";

    std::string query = std::format(R"(
        PRAGMA ydb.KMeansTreeSearchTopSize = "{5}";
        DECLARE $embedding as List<Float>;

        $TargetEmbedding = Knn::ToBinaryStringFloat($embedding);

        SELECT
            id,
            document,

```

Alternative approach

> **Warning**
>
> Passing vectors as `List<Float>` and converting on the YQL side with `Knn::ToBinaryStringFloat` has lower performance than client-side byte array encoding.

The same search with the query vector passed as `List<Float>`:

```java
import java.util.ArrayList;
import java.util.List;
import java.util.Optional;

import tech.ydb.common.transaction.TxMode;
import tech.ydb.query.tools.QueryReader;
import tech.ydb.query.tools.SessionRetryContext;
import tech.ydb.table.query.Params;
import tech.ydb.table.result.ResultSetReader;
import tech.ydb.table.values.ListType;
import tech.ydb.table.values.ListValue;
import tech.ydb.table.values.PrimitiveType;
import tech.ydb.table.values.PrimitiveValue;
import tech.ydb.table.values.Value;

List<ResultItem> searchItemsAsFloatList(
        SessionRetryContext retryCtx,
        String tableName,
        float[] embedding,
        String strategy,
        long limit,
        Optional<String> indexName) {

    String viewIndex = indexName.map(n -> "VIEW " + n).orElse("");
    String sortOrder = strategy.endsWith("Similarity") ? "DESC" : "ASC";

    String query = String.format("""
            DECLARE $embedding as List<Float>;

            $target_embedding = Knn::ToBinaryStringFloat($embedding);

            SELECT
                id,
                document,
                Knn::%s(embedding, $target_embedding) as score
            FROM %s %s
            ORDER BY score
            %s
            LIMIT %d;
            """, strategy, tableName, viewIndex, sortOrder, limit);

    Value<?>[] floats = new Value<?>[embedding.length];
    for (int i = 0; i < embedding.length; i++) {
        floats[i] = PrimitiveValue.newFloat(embedding[i]);
    }
    ListValue emb = ListType.of(PrimitiveType.Float).newValueOwn(floats);
    Params params = Params.of("$embedding", emb);

    QueryReader reader = retryCtx.supplyResult(session -> QueryReader.readFrom(
            session.createQuery(query, TxMode.SERIALIZABLE_RW, params)
    )).join().getValue();

    List<ResultItem> result = new ArrayList<>();
    ResultSetReader rs = reader.getResultSet(0);
    while (rs.next()) {

C#

Vector search examples for the .NET SDK are not available yet.

This functionality is not currently supported.

Track progress or vote for support: ydb-dotnet-sdk#657

JavaScript

Recommended approach

```javascript
const limit;
const embedding = convertVectorToBytes(new Float32Array([1.5, 2.5, 3.5]))

await sql`SELECT
    id,
    document,
    Knn::CosineSimilarity(embedding, ${embedding}) as score
FROM `table_name`
ORDER BY score DESC
LIMIT ${unsafe(limit)};
```

Alternative approach

> **Warning**
>
> Passing vectors as `List<Float>` and converting on the YQL side with `Knn::ToBinaryStringFloat` has lower performance than client-side byte array encoding.

```
const limit;
const embedding = new Float32Array([1.5, 2.5, 3.5])

await sql`SELECT
        id,
        document,
        Knn::CosineSimilarity(embedding, Knn::ToBinaryStringFloat(${embedding})) as score
    FROM `table_name`
    ORDER BY score DESC
    LIMIT ${unsafe(limit)};
```

Rust

```
let view_index = index_name.map(|n| format!("VIEW {n}")).unwrap_or_default();
let sort_order = if strategy.ends_with("Similarity") { "DESC" } else { "ASC" };

let mut stream = qc
    .query(search_query)
    .param("$embedding", convert_vector_to_bytes(&embedding))
    .await?;
while let Some(result_set) = stream.next_result_set().await? {
    for mut row in result_set {
        // id, document, score
    }
}
stream.close().await?;
```

PHP

Vector search examples for the PHP SDK are not available yet.

This functionality is not currently supported.

Track progress or vote for support: ydb-php-sdk#268

Full example

The following example combines all the steps above:

1. Dropping the existing table
2. Creating a new table
3. Inserting items
4. Searching for nearest vectors without an index
5. Adding a vector index
6. Searching for nearest vectors with the index

C++

```
void PrintResults(const std::vector<TResultItem>& items)
{
    if (items.empty()) {
        std::cout << "No items found" << std::endl;
        return;
    }

    for (const auto& item : items) {
        std::cout << "[score=" << item.Score << "] " << item.Id << ": " << item.Document << std::endl;
    }
}

void VectorExample(
    const std::string& endpoint,
    const std::string& database,
    const std::string& tableName,
    const std::string& indexName)
{
    auto driverConfig = NYdb::CreateFromEnvironment(endpoint + "/?database=" + database);
    NYdb::TDriver driver(driverConfig);
    NYdb::NQuery::TQueryClient client(driver);

    try {
        DropVectorTable(client, tableName);
        CreateVectorTable(client, tableName);
        std::vector<TItem> items = {
            {.Id = "1", .Document = "document 1", .Embedding = {0.98, 0.1, 0.01}},
            {.Id = "2", .Document = "document 2", .Embedding = {1.0, 0.05, 0.05}},
            {.Id = "3", .Document = "document 3", .Embedding = {0.9, 0.1, 0.1}},
            {.Id = "4", .Document = "document 4", .Embedding = {0.03, 0.0, 0.99}},
            {.Id = "5", .Document = "document 5", .Embedding = {0.0, 0.0, 0.99}},
            {.Id = "6", .Document = "document 6", .Embedding = {0.0, 0.02, 1.0}},
            {.Id = "7", .Document = "document 7", .Embedding = {0.0, 1.05, 0.05}},
            {.Id = "8", .Document = "document 8", .Embedding = {0.02, 0.98, 0.1}},
            {.Id = "9", .Document = "document 9", .Embedding = {0.0, 1.0, 0.05}},
        };
        InsertItemsAsBytes(client, tableName, items);
        PrintResults(SearchItemsAsBytes(client, tableName, {1.0, 0.0, 0.0}, "CosineSimilarity", 3));
        AddIndex(driver, client, database, tableName, indexName, "similarity=cosine", 3, 1, 3);
        PrintResults(SearchItemsAsBytes(client, tableName, {1.0, 0.0, 0.0}, "CosineSimilarity", 3, 10, indexN
ame));
    } catch (const std::exception& e) {
        std::cerr << "Execution failed: " << e.what() << std::endl;
    }

    driver.Stop(true);
}
```

Full source code is available at this link.

Go

Vector search is fully supported in the Go SDK. A complete example combining all operations above (table creation, data insert, index creation, search) is built from the code fragments on this page. See a working example in the ydb-go-sdk.

Java

The example combines steps from the sections above: `QueryClient` + `SessionRetryContext` for YQL and `TableClient` + `SessionRetryContext` for `ALTER TABLE` with index rename. Methods `createVectorTable`, `insertItemsAsBytes`, `searchItemsAsBytes`, `addVectorIndex`, and types `Item` / `ResultItem` are as in the corresponding fragments on this page.

```java
import java.util.List;
import java.util.Optional;

import tech.ydb.common.transaction.TxMode;
import tech.ydb.core.grpc.GrpcTransport;
import tech.ydb.query.QueryClient;
import tech.ydb.query.tools.QueryReader;
import tech.ydb.query.tools.SessionRetryContext;
import tech.ydb.table.TableClient;
import tech.ydb.table.query.Params;

public class VectorSearchJavaExample {

    record Item(String id, String document, float[] embedding) {}
    record ResultItem(String id, String document, float score) {}

    public static void main(String[] args) {
        String connectionString = System.getenv().getOrDefault("YDB_CONNECTION_STRING", "grpc://localhost:213
6/local");
        String tableName = "ydb_vector_search";
        String indexName = "ydb_vector_index";

        try (GrpcTransport transport = GrpcTransport.forConnectionString(connectionString).build();
            QueryClient queryClient = QueryClient.newClient(transport).build();
            TableClient tableClient = TableClient.newClient(transport).build()) {

            SessionRetryContext queryRetry = SessionRetryContext.create(queryClient).build();
            SessionRetryContext tableRetry = SessionRetryContext.create(tableClient).build();

            dropVectorTableIfExists(queryRetry, tableName);
            createVectorTable(queryRetry, tableName);

            List<Item> items = List.of(
                    new Item("1", "vector 1", new float[]{0.98f, 0.1f, 0.01f}),
                    new Item("2", "vector 2", new float[]{1.0f, 0.05f, 0.05f}),
                    new Item("3", "vector 3", new float[]{0.9f, 0.1f, 0.1f}),
                    new Item("4", "vector 4", new float[]{0.03f, 0.0f, 0.99f}),
                    new Item("5", "vector 5", new float[]{0.0f, 0.0f, 0.99f}),
                    new Item("6", "vector 6", new float[]{0.0f, 0.02f, 1.0f}),
                    new Item("7", "vector 7", new float[]{0.0f, 1.05f, 0.05f}),
                    new Item("8", "vector 8", new float[]{0.02f, 0.98f, 0.1f}),
                    new Item("9", "vector 9", new float[]{0.0f, 1.0f, 0.05f})
            );

            insertItemsAsBytes(queryRetry, tableName, items);
            printResults(searchItemsAsBytes(queryRetry, tableName, new float[]{1, 0, 0},
                    "CosineSimilarity", 3, Optional.empty()));

            addVectorIndex(transport, queryRetry, tableRetry, tableName, indexName,
                    "similarity=cosine", 3, 1, 3);

            printResults(searchItemsAsBytes(queryRetry, tableName, new float[]{1, 0, 0},
                    "CosineSimilarity", 3, Optional.of(indexName)));
        }
    }

    static void dropVectorTableIfExists(SessionRetryContext queryRetry, String tableName) {
        String ddl = String.format("DROP TABLE IF EXISTS `%s`", tableName);
        queryRetry.supplyResult(s -> QueryReader.readFrom(
                s.createQuery(ddl, TxMode.NONE, Params.empty())
        )).join().getValue();
        System.out.println("Vector table dropped");
    }

    static void printResults(List<ResultItem> items) {
        if (items.isEmpty()) {
            System.out.println("No items found");
            return;
        }
        for (ResultItem item : items) {
            System.out.printf("[score=%f] %s: %s%n", item.score(), item.id(), item.document());
        }
    }
}
```

The output matches the Python example above.

Python

Usage example

Native SDK

```
import os
import ydb

def print_results(items):
    if len(items) == 0:
        print("No items found")
        return

    for item in items:
        print(f"[score={item['score']}] {item['id']}: {item['document']}")

def drop_vector_table_if_exists(pool: ydb.QuerySessionPool, table_name: str) -> None:
    pool.execute_with_retries(f"DROP TABLE IF EXISTS `{table_name}`")

    print("Vector table dropped")

def main(
    ydb_endpoint: str,
    ydb_database: str,
    ydb_credentials: ydb.AbstractCredentials,
    table_name: str,
    index_name: str,
):
    driver = ydb.Driver(
        endpoint=ydb_endpoint,
        database=ydb_database,
        credentials=ydb_credentials,
    )
    driver.wait(5, fail_fast=True)
    pool = ydb.QuerySessionPool(driver)

    drop_vector_table_if_exists(pool, table_name)

    create_vector_table(pool, table_name)

    items = [
        {"id": "1", "document": "vector 1", "embedding": [0.98, 0.1, 0.01]},
        {"id": "2", "document": "vector 2", "embedding": [1.0, 0.05, 0.05]},
        {"id": "3", "document": "vector 3", "embedding": [0.9, 0.1, 0.1]},
        {"id": "4", "document": "vector 4", "embedding": [0.03, 0.0, 0.99]},
        {"id": "5", "document": "vector 5", "embedding": [0.0, 0.0, 0.99]},
        {"id": "6", "document": "vector 6", "embedding": [0.0, 0.02, 1.0]},
        {"id": "7", "document": "vector 7", "embedding": [0.0, 1.05, 0.05]},
        {"id": "8", "document": "vector 8", "embedding": [0.02, 0.98, 0.1]},
        {"id": "9", "document": "vector 9", "embedding": [0.0, 1.0, 0.05]},

    table_name: str,
    index_name: str,
):
    async with ydb.aio.Driver(
        endpoint=ydb_endpoint,
        database=ydb_database,
        credentials=ydb_credentials,
    ) as driver:
        await driver.wait(5, fail_fast=True)
        pool = ydb.aio.QuerySessionPool(driver)

        await drop_vector_table_if_exists(pool, table_name)

        await create_vector_table(pool, table_name)

        items = [
            {"id": "1", "document": "vector 1", "embedding": [0.98, 0.1, 0.01]},
            {"id": "2", "document": "vector 2", "embedding": [1.0, 0.05, 0.05]},
            {"id": "3", "document": "vector 3", "embedding": [0.9, 0.1, 0.1]},
            {"id": "4", "document": "vector 4", "embedding": [0.03, 0.0, 0.99]},
            {"id": "5", "document": "vector 5", "embedding": [0.0, 0.0, 0.99]},
            {"id": "6", "document": "vector 6", "embedding": [0.0, 0.02, 1.0]},
            {"id": "7", "document": "vector 7", "embedding": [0.0, 1.05, 0.05]},
            {"id": "8", "document": "vector 8", "embedding": [0.02, 0.98, 0.1]},
            {"id": "9", "document": "vector 9", "embedding": [0.0, 1.0, 0.05]},
        ]

        await insert_items_vector_as_bytes(pool, table_name, items)

        items = await search_items_vector_as_bytes(
            pool,
            table_name,
            embedding=[1, 0, 0],
            strategy="CosineSimilarity",
            limit=3,
        )
        print_results(items)

        await add_vector_index(
            pool,
            driver,
            table_name,
            index_name=index_name,
            strategy="similarity=cosine",
            dimension=3,
            levels=1,
            clusters=3,
        )

        items = await search_items_vector_as_bytes(
            pool,
            table_name,
            embedding=[1, 0, 0],
            index_name=index_name,
            strategy="CosineSimilarity",
            limit=3,
        )
        print_results(items)

        await pool.stop()

if __name__ == "__main__":
    asyncio.run(main(
        ydb_endpoint=os.environ.get("YDB_ENDPOINT", "grpc://localhost:2136"),
        ydb_database=os.environ.get("YDB_DATABASE", "/local"),
        ydb_credentials=ydb.credentials_from_env_variables(),
        table_name="ydb_vector_search",
```

```
        index_name="ydb_vector_index",
    ))
```

Program output:

```
Vector table dropped
Vector table created
9 items inserted
[score=0.997509241104126] 2: vector 2
[score=0.9947828650474548] 1: vector 1
[score=0.9878783822059631] 3: vector 3
Table index ydb_vector_index created.
[score=0.997509241104126] 2: vector 2
[score=0.9947828650474548] 1: vector 1
[score=0.9878783822059631] 3: vector 3
```

The table was created, 9 documents were added, and vector similarity search ran successfully both before and after adding the vector index.

Full source code is available at this link.

C#

Vector search examples for the .NET SDK are not available yet.

This functionality is not currently supported.

Track progress or vote for support: ydb-dotnet-sdk#657

JavaScript

Vector index creation and a full end-to-end program for the JavaScript SDK are not available yet.

This functionality is not currently supported.

Track progress or vote for support: ydb-js-sdk#627

Rust

Full example on GitHub: vector-search.rs.

```rust
// drop → create table → insert → search → add index → search with VIEW
drop_vector_table_if_exists(&mut qc, table_name).await?;
create_vector_table(&mut qc, table_name).await?;
insert_items_as_bytes(&mut qc, table_name, &items).await?;
let hits = search_items_as_bytes(&mut qc, table_name, &[1.0, 0.0, 0.0],
    "CosineSimilarity", 3, None).await?;
add_vector_index(&mut qc, table_name, index_name, "similarity=cosine", 3, 1, 3).await?;
let hits = search_items_as_bytes(&mut qc, table_name, &[1.0, 0.0, 0.0],
    "CosineSimilarity", 3, Some(index_name)).await?;
```

PHP

Vector search examples for the PHP SDK are not available yet.

This functionality is not currently supported.

Track progress or vote for support: ydb-php-sdk#268

Distributed lock

Consider a scenario where it is necessary to ensure that only one instance of a client application accesses a shared resource at any given time. To achieve this, the semaphore mechanism in YDB coordination nodes can be utilized.

Semaphore lease mechanism

In contrast to local multithreaded programming, clients in distributed systems do not directly acquire locks or semaphores. Instead, they lease them for a specified duration, which can be periodically renewed. Due to reliance on physical time which can vary between machines, clients and the server might encounter situations where multiple clients believe they have acquired the same semaphore simultaneously, even if the server's perspective differs. To reduce the likelihood of such occurrences, it is crucial to configure automatic time synchronization beforehand, both on servers hosting client applications and on the YDB side, ideally using a unified time source.

Therefore, while distributed locking through such mechanisms cannot guarantee the complete absence of simultaneous resource access, it can significantly lower the probability of such events. This approach serves as an optimization to prevent unnecessary competition among clients for a shared resource. Absolute guarantees against concurrent resource requests could be implemented on the resource side.

Code example

Go

```
for {
  if session, err := db.Coordination().CreateSession(ctx, path); err != nil {
    return fmt.Errorf("cannot create session: %v", err);
  }

  if lease, err := session.AcquireSemaphore(ctx,
    semaphore,
    coordination.Exclusive,
    options.WithEphemeral(true),
  ); err != nil {
    // the session is likely lost, try to create a new one and get the lock in it
    session.Close(ctx);
    continue;
  }

  // lock acquired, start processing
  select {
     case <-lease.Context().Done():
  }

  // lock released, end processing
}
```

Python

Native SDK

```
import ydb

def coordination_service_workflow(driver: ydb.Driver, node_path: str, semaphore_name: str):
    client = driver.coordination_client

    client.create_node(node_path)

    with client.session(node_path) as session:
        with session.semaphore(semaphore_name) as semaphore:
            print("Some exclusive work")
```

Native SDK (Asyncio)

```
import os
import ydb

async def coordination_service_workflow(driver: ydb.aio.Driver, node_path: str, semaphore_name: str):
    client = driver.coordination_client
    await client.create_node(node_path)
    async with client.session(node_path) as session:
        async with session.semaphore(semaphore_name) as semaphore:
            print("Some exclusive work")
```

JavaScript

```
import { Driver } from '@ydbjs/core'
import { CoordinationClient } from '@ydbjs/coordination'

const driver = new Driver('grpc://localhost:2136/local')
const client = new CoordinationClient(driver)

await using session = await client.createSession('/local/my-app')
await using lock = await session.mutex('job-lock').lock()
await doWork(lock.signal)

// For long lived applications

for await (let session of client.openSession('/local/my-app')) {
  let mutex = session.mutex('job-lock')

  try {
    // Blocks until the lock is acquired.
    await using lock = await mutex.lock()

    await doWork(lock.signal)
  } catch {
    if (session.signal.aborted) continue // session expired, retry
    throw error
  }

  break
}
```

Java

```
CoordinationClient client = CoordinationClient.newClient(transport);
client.createNode(nodePath).join().expectSuccess();

try (CoordinationSession session = client.createSession(nodePath)) {
    session.connect().join().expectSuccess();
    SemaphoreLease lease = session.acquireEphemeralSemaphore(semaphoreName, true, Duration.ofMinutes(5))
            .join().getValue();
    try {
        // exclusive access to the resource
    } finally {
        lease.release().join();
    }
}
```

Leader election

Consider a scenario where multiple application instances need to elect a leader among themselves and be aware of the current leader at any given time.

This scenario can be implemented using semaphores in YDB coordination nodes as follows:

1. A semaphore is created (for example, named `my-service-leader`) with `Limit=1`.
2. All application instances call `AcquireSemaphore` with `Count=1`, specifying their endpoint in the `Data` field.
3. Only one application instance's call will complete quickly, while others will be queued. The application instance whose call completes successfully becomes the current leader.
4. All application instances call `DescribeSemaphore` with `WatchOwners=true` and `IncludeOwners=true`. The result's `Owners` field will contain at most one element, from which the current leader's endpoint can be determined via its `Data` field.
5. When the leader changes, `OnChanged` is called. In this case, application instances make a similar `DescribeSemaphore` call to learn about the new leader.

Service discovery

Consider a scenario where application instances are dynamically started and publish their endpoints, while other clients need to receive this list and respond to its changes.

This scenario can be implemented using semaphores in YDB coordination nodes as follows:

1. Create a semaphore (for example, named `my-service-endpoints`) with `Limit=Max<ui64>()`.
2. All application instances call `AcquireSemaphore` with `Count=1`, specifying their endpoint in the `Data` field.
3. Since the semaphore limit is very high, all `AcquireSemaphore` calls should complete quickly.
4. At this point, publication is complete, and application instances only need to respond to session stops by republishing themselves through a new session.
5. Clients call `DescribeSemaphore` with `IncludeOwners=true` and optionally with `WatchOwners=true`. In the result, the `Owners` field's `Data` will contain the endpoints of registered application instances.
6. When the list of endpoints changes, `OnChanged` is called. In this case, clients make a similar `DescribeSemaphore` call and receive the updated list.

Configuration publication

Let's consider a scenario where we need to publish a small configuration for multiple application instances that should promptly react to its changes.

This scenario can be implemented using semaphores in YDB coordination nodes as follows:

1. A semaphore is created (for example, named `my-service-config`).
2. The updated configuration is published through `UpdateSemaphore`.
3. Application instances call `DescribeSemaphore` with `WatchData=true`. In the result, the `Data` field will contain the current version of the configuration.
4. When the configuration changes, `OnChanged` is called. In this case, application instances make a similar `DescribeSemaphore` call and receive the updated configuration.

Diagnosing problems

When diagnosing problems related to YDB, diagnostic tools help: logging, metrics, and distributed tracing. It is recommended to enable them in advance, before problems occur, so that when investigating an incident, you can see the full picture of the system state before, during, and after the failure.

This section contains code recipes for enabling diagnostic tools in different YDB SDKs.

Contents:

- Enable logging
- Connect metrics to Prometheus
- Tracing with OpenTelemetry
- Connect tracing to Jaeger

Enabling logging

Below are examples of code that enables logging in different YDB SDKs.

Go

Native SDK

There are several ways to enable logs in an application that uses `ydb-go-sdk`:

Using the `YDB_LOG_SEVERITY_LEVEL` environment variable

This environment variable enables the built-in `ydb-go-sdk` logger (synchronous, non-block) and prints to the standard output stream.
You can set the environment variable as follows:

```
export YDB_LOG_SEVERITY_LEVEL=info
```

(possible values: `trace`, `debug`, `info`, `warn`, `error`, `fatal`, and `quiet`, defaults to `quiet`).

Enable a third-party logger `go.uber.org/zap`

```
package main

import (
  "context"
  "os"

  "go.uber.org/zap"

  ydbZap "github.com/ydb-platform/ydb-go-sdk-zap"
  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/trace"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  var log *zap.Logger // zap-logger with init out of this scope
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydbZap.WithTraces(
      log,
      trace.DetailsAll,
    ),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  ...
}
```

Enable a third-party logger `github.com/rs/zerolog`

```
package main

import (
  "context"
  "os"

  "github.com/rs/zerolog"

  ydbZerolog "github.com/ydb-platform/ydb-go-sdk-zerolog"
  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/trace"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  var log zerolog.Logger // zap-logger with init out of this scope
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydbZerolog.WithTraces(
      &log,
      trace.DetailsAll,
    ),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  ...
}
```

Enable a custom logger implementation `github.com/ydb-platform/ydb-go-sdk/v3/log.Logger`

```
package main

import (
  "context"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/log"
  "github.com/ydb-platform/ydb-go-sdk/v3/trace"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  var logger log.Logger // logger implementation with init out of this scope
  db, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithLogger(
      logger,
      trace.DetailsAll,
    ),
  )
  if err != nil {
    panic(err)
  }
  defer db.Close(ctx)
  ...
}
```

Implement your own logging package

You can implement your own logging package based on the driver events in the `github.com/ydb-platform/ydb-go-sdk/v3/trace` tracing package. The `github.com/ydb-platform/ydb-go-sdk/v3/trace` tracing package describes all logged driver events.

Iterate over server errors with `IterateByIssues`

When using YDB through the Go SDK, you can enable logging of requests and responses and also obtain detailed information about server errors (issues) — extra messages YDB returns in the response when operations fail. To iterate over issues in the server response, use IterateByIssues.

database/sql

There are several ways to enable logs in an application that uses `ydb-go-sdk`:

Using the `YDB_LOG_SEVERITY_LEVEL` environment variable

This environment variable enables the built-in `ydb-go-sdk` logger (synchronous, non-block) and prints to the standard output stream.
You can set the environment variable as follows:

```
export YDB_LOG_SEVERITY_LEVEL=info
```

(possible values: `trace`, `debug`, `info`, `warn`, `error`, `fatal`, and `quiet`, defaults to `quiet`).

Enable a third-party logger `go.uber.org/zap`

```
package main

import (
  "context"
  "database/sql"
  "os"

  "go.uber.org/zap"

  ydbZap "github.com/ydb-platform/ydb-go-sdk-zap"
  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/trace"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  var log *zap.Logger // zap-logger with init out of this scope
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydbZap.WithTraces(
      log,
      trace.DetailsAll,
    ),
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)

  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }
  defer connector.Close()

  db := sql.OpenDB(connector)
  defer db.Close()
  ...
}
```

Enable a third-party logger `github.com/rs/zerolog`

```
package main

import (
  "context"
  "database/sql"
  "os"

  "github.com/rs/zerolog"

  ydbZerolog "github.com/ydb-platform/ydb-go-sdk-zerolog"
  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/trace"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  var log zerolog.Logger // zap-logger with init out of this scope
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydbZerolog.WithTraces(
      &log,
      trace.DetailsAll,
    ),
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)

  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }
  defer connector.Close()

  db := sql.OpenDB(connector)
  defer db.Close()
  ...
}
```

Enable a custom logger implementation `github.com/ydb-platform/ydb-go-sdk/v3/log.Logger`

```
package main

import (
  "context"
  "database/sql"
  "os"

  "github.com/ydb-platform/ydb-go-sdk/v3"
  "github.com/ydb-platform/ydb-go-sdk/v3/log"
  "github.com/ydb-platform/ydb-go-sdk/v3/trace"
)

func main() {
  ctx, cancel := context.WithCancel(context.Background())
  defer cancel()
  var logger log.Logger // logger implementation with init out of this scope
  nativeDriver, err := ydb.Open(ctx,
    os.Getenv("YDB_CONNECTION_STRING"),
    ydb.WithLogger(
      logger,
      trace.DetailsAll,
    ),
  )
  if err != nil {
    panic(err)
  }
  defer nativeDriver.Close(ctx)

  connector, err := ydb.Connector(nativeDriver)
  if err != nil {
    panic(err)
  }
  defer connector.Close()

  db := sql.OpenDB(connector)
  defer db.Close()
  ...
}
```

Implement your own logging package

You can implement your own logging package based on the driver events in the `github.com/ydb-platform/ydb-go-sdk/v3/trace` tracing package. The `github.com/ydb-platform/ydb-go-sdk/v3/trace` tracing package describes all logged driver events.

Java

Native SDK

For logging purposes, the YDB Java SDK uses the slf4j library, which supports multiple logging levels (`error`, `warn`, `info`, `debug`, `trace`) for one or many loggers. The current implementation supports the following loggers:

- The `tech.ydb.core.grpc` logger provides information about the internal gRPC implementation
- The `debug` level logs all gRPC operations; use it only for debugging
- The `info` level is recommended by default
- On the `debug` level, the `tech.ydb.table.impl` logger lets you track the internal state of the YDB driver, including the session pool
- On the `debug` level, the `tech.ydb.table.SessionRetryContext` logger reports the number of retries, query results, per-retry duration, and total operation time
- On the `debug` level, the `tech.ydb.table.Session` logger provides the query text, response status, and execution time for session operations

Enabling and configuring the Java SDK loggers depends on the `slf4j-api` implementation you use.
Here is an example `log4j2` configuration for the `log4j-slf4j-impl` library:

```
<Configuration status="WARN">
  <Appenders>
    <Console name="Console" target="SYSTEM_OUT">
      <PatternLayout pattern="%d{HH:mm:ss.SSS} [%t] %-5level %logger{36} - %msg%n"/>
    </Console>
  </Appenders>

  <Loggers>
    <Logger name="io.netty" level="warn" additivity="false">
      <AppenderRef ref="Console"/>
    </Logger>
    <Logger name="io.grpc.netty" level="warn" additivity="false">
      <AppenderRef ref="Console"/>
    </Logger>
    <Logger name="tech.ydb.core.grpc" level="info" additivity="false">
      <AppenderRef ref="Console"/>
    </Logger>
    <Logger name="tech.ydb.table.impl" level="info" additivity="false">
      <AppenderRef ref="Console"/>
    </Logger>
    <Logger name="tech.ydb.table.SessionRetryContext" level="debug" additivity="false">
      <AppenderRef ref="Console"/>
    </Logger>
    <Logger name="tech.ydb.table.Session" level="debug" additivity="false">
      <AppenderRef ref="Console"/>
    </Logger>

    <Root level="debug" >
      <AppenderRef ref="Console"/>
    </Root>
  </Loggers>
</Configuration>
```

JDBC

The JDBC driver uses the same logging stack via `slf4j`; configure the `tech.ydb.*` loggers the same way as in the native SDK.

The same debug logs are available in other stacks built on JDBC (Spring Boot, ORMs, connection pools, and so on): they reach YDB through this driver, so it is enough to attach the same `slf4j` / log4j2 / logback configuration in the application.

PHP

For logging purposes, you need to use a class, that implements `\Psr\Log\LoggerInterface`.
`ydb-php-sdk` has build-in loggers in `YdbPlatform\Ydb\Logger` namespace:

- `NullLogger` - default logger, which writes nothing
- `SimpleStdLogger($level)` - logger, which writes to logs in stderr.

Usage example:

```
$config = [
  'logger' => new \YdbPlatform\Ydb\Logger\SimpleStdLogger(\YdbPlatform\Ydb\Logger\SimpleStdLogger::INFO)
]
$ydb = new \YdbPlatform\Ydb\Ydb($config);
```

Python

The Python SDK uses the standard `logging` library. To enable a specific logging level:

```
import logging

logging.getLogger('ydb').setLevel(logging.DEBUG)
```

JavaScript

The SDK uses the debug library for logging.
To enable logs, set the `DEBUG` environment variable to filter SDK events, for example `DEBUG=ydbjs:*`.

Enabling metrics in Prometheus

Below are examples of the code for enabling metrics in Prometheus in different YDB SDKs.

Go

Native SDK

```
package main

import (
    "context"

    "github.com/prometheus/client_golang/prometheus"
    metrics "github.com/ydb-platform/ydb-go-sdk-prometheus/v2"
    "github.com/ydb-platform/ydb-go-sdk/v3"
    "github.com/ydb-platform/ydb-go-sdk/v3/trace"
)

func main() {
    ctx := context.Background()
    registry := prometheus.NewRegistry()
    db, err := ydb.Open(ctx,
        os.Getenv("YDB_CONNECTION_STRING"),
        metrics.WithTraces(
            registry,
            metrics.WithDetails(trace.DetailsAll),
            metrics.WithSeparator("_"),
        ),
    )
    if err != nil {
        panic(err)
    }
    defer db.Close(ctx)
    ...
}
```

database/sql

```
package main

import (
    "context"
    "database/sql"

    "github.com/prometheus/client_golang/prometheus"
    metrics "github.com/ydb-platform/ydb-go-sdk-prometheus/v2"
    "github.com/ydb-platform/ydb-go-sdk/v3"
    "github.com/ydb-platform/ydb-go-sdk/v3/trace"
)

func main() {
    ctx := context.Background()
    registry := prometheus.NewRegistry()
    nativeDriver, err := ydb.Open(ctx,
        os.Getenv("YDB_CONNECTION_STRING"),
        metrics.WithTraces(
            registry,
            metrics.WithDetails(trace.DetailsAll),
            metrics.WithSeparator("_"),
        ),
    )
    if err != nil {
        panic(err)
    }
    defer nativeDriver.Close(ctx)

    connector, err := ydb.Connector(nativeDriver)
    if err != nil {
        panic(err)
    }

    db := sql.OpenDB(connector)
    defer db.Close()
    ...
}
```

Java

This functionality is not currently supported.

This functionality is not currently supported.

JavaScript

This section is under development.

Rust

This functionality is not currently supported.

Track progress or vote for Rust SDK support: ydb-rs-sdk#267

Tracing with OpenTelemetry

YDB SDK instruments Query Service operations with OpenTelemetry spans, providing distributed tracing from application code to each gRPC call to YDB. The spans are exported via the standard OTLP protocol and are compatible with Jaeger, Grafana Tempo, Zipkin, and any other backend that supports OpenTelemetry.

Created spans

Currently, spans are supported for Query Service operations. Support for topics and other services is planned for future SDK versions.

The following spans are created:

Span	Type	Description
`ydb.RunWithRetry`	`Internal`	Covers the entire retry cycle for a single operation
`ydb.Try`	`Internal`	One span per attempt, including the first; child RPC spans are attached to it
`ydb.CreateSession`	`Client`	Creating a session via gRPC `CreateSession` and `AttachStream`
`ydb.ExecuteQuery`	`Client`	Execution of one YQL query
`ydb.BeginTransaction`	`Client`	Explicit call to start a transaction
`ydb.Commit`	`Client`	Transaction commit
`ydb.Rollback`	`Client`	Transaction rollback
`ydb.Driver.Initialize`	`Internal`	Initial driver initialization: cluster discovery and authentication

A typical span tree for a transactional operation with retry looks as follows:

```
ydb.RunWithRetry  (Internal)
├─ ydb.Try        (Internal)   ← 1st attempt: ERROR
│  ├─ ydb.ExecuteQuery (Client)
│  ├─ ydb.ExecuteQuery (Client)
│  └─ ydb.Commit       (Client) ← ERROR: Transaction Lock Invalidated
└─ ydb.Try        (Internal)   ← 2nd attempt: SUCCESS, ydb.retry.backoff_ms=50
   ├─ ydb.ExecuteQuery (Client)
   ├─ ydb.ExecuteQuery (Client)
   └─ ydb.Commit       (Client)
```

`ydb.RunWithRetry` is the parent span for the entire retry operation. For each execution attempt, a separate child span `ydb.Try` is created: the first `ydb.Try` corresponds to the first attempt, the second to the first **retry** attempt, and so on. RPC spans of a specific attempt, for example `ydb.ExecuteQuery` and `ydb.Commit`, are created inside the corresponding `ydb.Try`.

> **Note**
>
> If an attempt ends with an error, its span `ydb.Try` ends with an error status. On a retry, a new `ydb.Try` is created; starting from the second attempt, the attribute `ydb.retry.backoff_ms` — the wait time before this attempt in milliseconds — is set on it. This wait time is included in the duration of the next span `ydb.Try`: the span starts before the backoff pause, then after the pause, the RPC calls of this attempt are executed.

Span attributes

The SDK uses both standard OpenTelemetry semantic conventions attributes and YDB-specific extensions.

Standard OpenTelemetry attributes

The following attributes belong to the stable OpenTelemetry semantic conventions and can be processed by tracing backends as standard:

Attribute	Where installed	Description
`db.system.name`	RPC spans	Always `"ydb"`
`db.namespace`	RPC spans	Path to YDB database
`server.address`	RPC spans	Main host from the connection string
`server.port`	RPC spans	Main port from the connection string
`network.peer.address`	RPC spans	Actual gRPC endpoint used for the call
`network.peer.port`	RPC spans	Actual gRPC endpoint port used for the call
`error.type`	Spans that failed	Error type. For example: `"transport_error"`, `"ydb_error"` or the full exception class name
`db.response.status_code`	RPC spans during `YdbException`	Textual name of the YDB status from the error, for example `ABORTED`, `UNAVAILABLE`, `OVERLOADED`

YDB-specific attributes

The following attributes are YDB extensions on top of the standard semantic conventions:

Attribute	Where it is installed	Description

`ydb.node.id`	RPC spans	ID of the YDB node that processed the query
`ydb.node.dc`	RPC spans	Data center of the YDB node that processed the query
`ydb.retry.backoff_ms`	Spans `ydb.Try`, starting from the second attempt	Wait time before retry in milliseconds

W3C trace context

The SDK automatically propagates the W3C `traceparent` header in every outgoing gRPC call. This allows the YDB server to trace internal operations within the same trace, without additional configuration. For more details about server-side tracing, see the section Passing an external trace-id to YDB.

Connecting to the SDK

Go

Install the OpenTelemetry adapter for the YDB Go SDK:

```
go get github.com/ydb-platform/ydb-go-sdk-otel
```

Configure `TracerProvider` and pass the adapter to `ydb.Open`:

```
package main

import (
    "context"
    "os"

    "go.opentelemetry.io/otel"
    "go.opentelemetry.io/otel/attribute"
    "go.opentelemetry.io/otel/exporters/otlp/otlptrace/otlptracegrpc"
    "go.opentelemetry.io/otel/sdk/resource"
    sdktrace "go.opentelemetry.io/otel/sdk/trace"

    "github.com/ydb-platform/ydb-go-sdk/v3"
    ydbOtel "github.com/ydb-platform/ydb-go-sdk-otel"
)

func main() {
    ctx := context.Background()

    exporter, err := otlptracegrpc.New(ctx,
        otlptracegrpc.WithEndpoint("localhost:4317"),
        otlptracegrpc.WithInsecure(),
    )
    if err != nil {
        panic(err)
    }
    res, _ := resource.Merge(resource.Default(), resource.NewSchemaless(
        attribute.String("service.name", "my-service"),
    ))
    tp := sdktrace.NewTracerProvider(
        sdktrace.WithBatcher(exporter),
        sdktrace.WithResource(res),
    )
    defer tp.Shutdown(ctx)
    otel.SetTracerProvider(tp)

    db, err := ydb.Open(ctx,
        os.Getenv("YDB_CONNECTION_STRING"),
        ydbOtel.WithTraces(
            ydbOtel.WithTracer(tp.Tracer("ydb-go-sdk")),
        ),
    )
    if err != nil {
        panic(err)
    }
    defer db.Close(ctx)
}
```

Python

Install additional dependencies `opentelemetry` and the OTLP exporter:

```
pip install ydb[opentelemetry]
pip install opentelemetry-exporter-otlp-proto-grpc
```

Call `enable_tracing()` after configuring the global `TracerProvider`:

```python
from opentelemetry import trace
from opentelemetry.sdk.trace import TracerProvider
from opentelemetry.sdk.trace.export import BatchSpanProcessor
from opentelemetry.exporter.otlp.proto.grpc.trace_exporter import OTLPSpanExporter
from opentelemetry.sdk.resources import Resource

import ydb
from ydb.opentelemetry import enable_tracing

resource = Resource(attributes={"service.name": "my-service"})
provider = TracerProvider(resource=resource)
provider.add_span_processor(
    BatchSpanProcessor(OTLPSpanExporter(endpoint="http://localhost:4317"))
)
trace.set_tracer_provider(provider)

enable_tracing()

with ydb.Driver(endpoint="grpc://localhost:2136", database="/local") as driver:
    driver.wait(timeout=5)
    with ydb.QuerySessionPool(driver) as pool:
        pool.execute_with_retries("SELECT 1")

provider.shutdown()
```

C#

Add the NuGet package:

```
dotnet add package Ydb.Sdk.OpenTelemetry
```

Register the YDB instrumentation when configuring OpenTelemetry in your service:

```
services.AddOpenTelemetry()
    .WithTracing(builder => builder
        .AddYdb()
        .AddOtlpExporter());
```

Java

Add YDB SDK and OpenTelemetry dependencies (example for Maven):

```
<dependency>
    <groupId>tech.ydb</groupId>
    <artifactId>ydb-sdk-core</artifactId>
    <version>${ydb.sdk.version}</version>
</dependency>
<dependency>
    <groupId>io.opentelemetry</groupId>
    <artifactId>opentelemetry-sdk</artifactId>
    <version>${otel.version}</version>
</dependency>
<dependency>
    <groupId>io.opentelemetry</groupId>
    <artifactId>opentelemetry-exporter-otlp</artifactId>
    <version>${otel.version}</version>
</dependency>
```

Create an instance of the OpenTelemetry SDK and pass it to the transport via `OpenTelemetryTracer`:

```
import io.opentelemetry.api.OpenTelemetry;
import io.opentelemetry.exporter.otlp.trace.OtlpGrpcSpanExporter;
import io.opentelemetry.sdk.OpenTelemetrySdk;
import io.opentelemetry.sdk.resources.Resource;
import io.opentelemetry.sdk.trace.SdkTracerProvider;
import io.opentelemetry.sdk.trace.export.BatchSpanProcessor;
import io.opentelemetry.semconv.resource.attributes.ResourceAttributes;
import tech.ydb.core.auth.CloudAuthHelper;
import tech.ydb.core.grpc.GrpcTransport;
import tech.ydb.core.opentelemetry.OpenTelemetryTracer;
import tech.ydb.query.QueryClient;

Resource resource = Resource.getDefault().toBuilder()
    .put(ResourceAttributes.SERVICE_NAME, "my-service")
    .build();

SdkTracerProvider tracerProvider = SdkTracerProvider.builder()
    .setResource(resource)
    .addSpanProcessor(BatchSpanProcessor.builder(
        OtlpGrpcSpanExporter.builder()
            .setEndpoint("http://localhost:4317")
            .build()
    ).build())
    .build();

OpenTelemetry openTelemetry = OpenTelemetrySdk.builder()
    .setTracerProvider(tracerProvider)
    .build();

try (GrpcTransport transport = GrpcTransport.forConnectionString(connectionString)
        .withAuthProvider(CloudAuthHelper.getAuthProviderFromEnviron())
        .withTracer(OpenTelemetryTracer.fromOpenTelemetry(openTelemetry))
        .build();
     QueryClient queryClient = QueryClient.newClient(transport).build()) {
    // Use queryClient here
}
```

When using the JDBC driver, simply add the `enableOpenTelemetryTracer=true` parameter to the connection string — the driver will pick up the global OTel provider automatically:

```
jdbc:ydb://<host>:<port>/<database>?enableOpenTelemetryTracer=true
```

C++

Include the OpenTelemetry tracing header from the YDB C++ SDK and add a dependency on the OTel C++ SDK:

```
#include <ydb-cpp-sdk/client/driver/driver.h>
#include <ydb-cpp-sdk/open_telemetry/trace.h>

#include <opentelemetry/exporters/otlp/otlp_http_exporter_factory.h>
#include <opentelemetry/exporters/otlp/otlp_http_exporter_options.h>
#include <opentelemetry/sdk/trace/tracer_provider.h>
#include <opentelemetry/sdk/trace/simple_processor_factory.h>
#include <opentelemetry/sdk/resource/resource.h>
#include <opentelemetry/trace/provider.h>

namespace sdktrace = opentelemetry::sdk::trace;
namespace otlp     = opentelemetry::exporter::otlp;
namespace resource = opentelemetry::sdk::resource;
using namespace NYdb;

// 1. Initialize the OTel tracing provider
otlp::OtlpHttpExporterOptions opts;
opts.url = "http://localhost:4318/v1/traces";
auto exporter  = otlp::OtlpHttpExporterFactory::Create(opts);
auto processor = sdktrace::SimpleSpanProcessorFactory::Create(std::move(exporter));
auto res       = resource::Resource::Create({{"service.name", "my-service"}});
auto otelProvider = std::make_shared<sdktrace::TracerProvider>(
    std::move(processor), res);
opentelemetry::trace::Provider::SetTracerProvider(otelProvider);

// 2. Wrap in the YDB tracing provider
auto ydbTraceProvider = NTrace::CreateOtelTraceProvider(otelProvider);

// 3. Create a YDB driver with tracing enabled
auto driverConfig = TDriverConfig()
    .SetEndpoint("localhost:2136")
    .SetDatabase("/local")
    .SetTraceProvider(ydbTraceProvider);

TDriver driver(driverConfig);
```

JavaScript

Install `@ydbjs/telemetry` together with the OpenTelemetry Node SDK and OTLP exporter:

```
npm install @ydbjs/telemetry @opentelemetry/sdk-node @opentelemetry/exporter-trace-otlp-http
```

Initialize `NodeSDK` before creating the driver and call `register()` from `@ydbjs/telemetry`:

```
import { NodeSDK } from '@opentelemetry/sdk-node'
import { OTLPTraceExporter } from '@opentelemetry/exporter-trace-otlp-http'
import { Driver } from '@ydbjs/core'
import { query } from '@ydbjs/query'
import { register } from '@ydbjs/telemetry'

const sdk = new NodeSDK({
    serviceName: 'my-service',
    traceExporter: new OTLPTraceExporter({ url: 'http://localhost:4318/v1/traces' }),
})
sdk.start()

// Must be called BEFORE creating the Driver — W3C propagation middleware
// trace context is set once during driver construction.
const instrumentation = register()

using driver = new Driver(process.env.YDB_CONNECTION_STRING)
await driver.ready()
await using sql = query(driver)
// ...

instrumentation.disable()
await sdk.shutdown()
```

Alternatively, use `--import` for auto-loading before starting the application:

```
node --import @opentelemetry/sdk-node/register --import @ydbjs/telemetry/register your-app.js
```

Enabling tracing in Jaeger

Below are code examples for enabling tracing in Jaeger in different YDB SDK.

C++

This functionality is not currently supported.

Go

Native SDK

```
package main

import (
    "context"
    "time"

    "github.com/opentracing/opentracing-go"
    jaegerConfig "github.com/uber/jaeger-client-go/config"

    "github.com/ydb-platform/ydb-go-sdk/v3"
    "github.com/ydb-platform/ydb-go-sdk/v3/trace"

    tracing "github.com/ydb-platform/ydb-go-sdk-opentracing"
)

const (
    tracerURL   = "localhost:5775"
    serviceName = "ydb-go-sdk"
)

func main() {
    tracer, closer, err := jaegerConfig.Configuration{
        ServiceName: serviceName,
        Sampler: &jaegerConfig.SamplerConfig{
            Type:  "const",
            Param: 1,
        },
        Reporter: &jaegerConfig.ReporterConfig{
            LogSpans:            true,
            BufferFlushInterval: 1 * time.Second,
            LocalAgentHostPort:  tracerURL,
        },
    }.NewTracer()
    if err != nil {
        panic(err)
    }

    defer closer.Close()

    // set global tracer of this application
    opentracing.SetGlobalTracer(tracer)

    span, ctx := opentracing.StartSpanFromContext(context.Background(), "client")
    defer span.Finish()

    db, err := ydb.Open(ctx,
        os.Getenv("YDB_CONNECTION_STRING"),
        tracing.WithTraces(tracing.WithDetails(trace.DetailsAll)),
    )
    if err != nil {
        panic(err)
    }
    defer db.Close(ctx)
    ...
}
```

database/sql

```
package main

import (
    "context"
    "database/sql"
    "time"

    "github.com/opentracing/opentracing-go"
    jaegerConfig "github.com/uber/jaeger-client-go/config"

    "github.com/ydb-platform/ydb-go-sdk/v3"
    "github.com/ydb-platform/ydb-go-sdk/v3/trace"

    tracing "github.com/ydb-platform/ydb-go-sdk-opentracing"
)

const (
    tracerURL   = "localhost:5775"
    serviceName = "ydb-go-sdk"
)

func main() {
    tracer, closer, err := jaegerConfig.Configuration{
        ServiceName: serviceName,
            Sampler: &jaegerConfig.SamplerConfig{
            Type:  "const",
            Param: 1,
        },
        Reporter: &jaegerConfig.ReporterConfig{
            LogSpans:            true,
            BufferFlushInterval: 1 * time.Second,
            LocalAgentHostPort:  tracerURL,
        },
    }.NewTracer()
    if err != nil {
        panic(err)
    }

    defer closer.Close()

    // set global tracer of this application
    opentracing.SetGlobalTracer(tracer)

    span, ctx := opentracing.StartSpanFromContext(context.Background(), "client")
    defer span.Finish()

    nativeDriver, err := ydb.Open(ctx,
        os.Getenv("YDB_CONNECTION_STRING"),
        tracing.WithTraces(tracing.WithDetails(trace.DetailsAll)),
    )
    if err != nil {
        panic(err)
    }
    defer nativeDriver.Close(ctx)

    connector, err := ydb.Connector(nativeDriver)
    if err != nil {
        panic(err)
    }

    db := sql.OpenDB(connector)
    defer db.Close()
    ...
}
```

Convert a table between row-oriented and column-oriented

YDB supports two main types of tables: row-oriented and column-oriented. The chosen table type determines the physical representation of data on disks, so changing the type in place is impossible. However, you can create a new table of a different type and copy the data. This recipe consists of the following steps:

1. Prepare a new table
2. Copy data
3. Switch the workload *(optional)*

These instructions assume that the source table is row-oriented, and the goal is to obtain a similar column-oriented destination table; however, the table roles could be swapped.

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Prepare a new table

Take a copy of the original `CREATE TABLE` statement used for the source table. Modify the following to create a file with the `CREATE TABLE` query for the destination table:

1. Change the table name to a desired new name.
2. Set the `STORE` setting value to `COLUMN` to make it a column-oriented table.

Run this query (assuming it is saved in a file named `create_column_oriented_table.yql`):

```
$ ydb -p quickstart yql -f create_column_oriented_table.yql
```

Example test data and table schemas

Row-oriented source table:

```
CREATE TABLE `row_oriented_table` (
    id Int64 NOT NULL,
    metric_a Double,
    metric_b Double,
    metric_c Double,
    PRIMARY KEY (id)
)
```

Column-oriented destination table:

```
CREATE TABLE `column_oriented_table` (
    id Int64 NOT NULL,
    metric_a Double,
    metric_b Double,
    metric_c Double,
    PRIMARY KEY (id)
)
PARTITION BY HASH(id)
WITH (STORE = COLUMN)
```

> **Note**
>
> Refer to the documentation for application developers to learn more about partitioning column-oriented tables and choosing a partitioning key (`PARTITION BY` clause).

Fill the source row-oriented table with random data:

```
INSERT INTO `row_oriented_table` (id, metric_a, metric_b, metric_c)
SELECT
    id,
    Random(id + 1),
    Random(id + 2),
    Random(id + 3)
FROM (
    SELECT ListFromRange(1, 1000) AS id
) FLATTEN LIST BY id
```

Copy data

Currently, the recommended way to copy data between YDB tables of different types is to export and import:

1. Export data to the local filesystem:

```
$ ydb -p quickstart dump -p row_oriented_table -o tmp_backup/
```

2. Import it back into another YDB table:

```
ydb -p quickstart import file csv -p column_oriented_table tmp_backup/row_oriented_table/*.csv
```

Make sure you have enough free space in the file system to store all the data.

Switch the workload

It is currently impossible to seamlessly replace the original table with a newly created column-oriented one. However, if necessary, you can gradually switch your queries to work with the new table by replacing the original table path in the queries with the new one.

If the original table is no longer needed, it can be dropped with `ydb -p quickstart table drop row_oriented_table` or `yql -p quickstart yql -s "DROP TABLE row_oriented_table"`.

Conducting load testing

YDB CLI has a built-in toolkit for performing load testing using standard benchmarks:

Benchmark	Reference
TPC-C	tpcc
TPC-H	tpch
TPC-DS	tpcds
ClickBench	clickbench

Also, there is a possibility to run user-defined testing scenarios, which are initiated via the `ydb workload query` command, see the description. The details are provided in the corresponding section.

All mentioned methods emulate the user's workload under the given scenarios. The detailed description of each method is provided in the corresponding sections, the links to which are provided above.

All commands for working with benchmarks are organized into corresponding groups, and the database path is specified in the same way for all commands:

```
ydb workload tpcc --path path/in/database ...
ydb workload tpch --path path/in/database ...
ydb workload tpcds --path path/in/database ...
ydb workload clickbench --path path/in/database ...
ydb workload query --path path/in/database ...
```

Load testing consists of three stages:

1. Data preparation
2. Testing
3. Cleanup

Data preparation

It consists of two steps: initializing tables and filling them with data.

Initialization

Initialization is performed by the `init` command:

```
ydb workload tpcc --path tpcc/10wh init
ydb workload clickbench --path clickbench/hits init --store=row
ydb workload tpch --path tpch/s1 init --store=column
ydb workload tpcds --path tpcds/s1 init --store=external-s3
ydb workload query --path user/suite1 init --suite-path /home/user/user_suite
```

At the stage of creating tables, for `tpch`, `tpcds`, and `clickbench`, you can configure the tables to be created:

- Select the type of tables to be used: row, column, external, etc. (parameter `--store`);
- Select the types of columns to be used: some data types from the original benchmarks can be represented by multiple YDB data types. In such cases, it is possible to select a specific one with `--string`, `--datetime`, and `--float-mode` parameters.

You can also specify that tables should be deleted before creation if they already exist using the `--clear` parameter.

For more details, see the relevant reference sections:

- tpcc init
- clickbench init
- tpch init
- tpcds init
- query init

Loading data into the tables

The `import` command is used to load data into the benchmark tables. This command is specific to each benchmark, and its behavior depends on the subcommands. However, there are also parameters common to all benchmarks.

For more details, see the relevant reference sections:

- tpcc import
- tpch import
- tpcds import
- clickbench import

Examples:

```
ydb workload tpcc --path tpcc/10wh import
ydb workload clickbench --path clickbench/hits import files --input hits.csv.gz
ydb workload tpch --path tpch/s1 import generator --scale 1
ydb workload tpcds --path tpcds/s1 import generator --scale 1
ydb workload query --path user/suite1 import --suite-path /home/user/user_suite
```

Testing

The performance testing is performed using the `run` command. Its behavior is mostly the same across different benchmarks, though some differences do exist.

Examples:

```
ydb workload tpcc --path tpcc/10wh run
ydb workload clickbench --path clickbench/hits run --include 1-5,8
ydb workload tpch --path tpch/s1 run --exclude 3,4 --iterations 3
ydb workload tpcds --path tpcds/s1 run --plan ~/query_plan --include 2 --iterations 5
ydb workload query --path user/suite1 run --plan ~/query_plan --include first_query_set.1.sql,second_query_se
t.2.sql --iterations 5
```

The command 'run' for each benchmark has a number of additional parameters for configuring the types of reports generated, collecting statistics, and other results of load testing.

For more details, see the relevant reference sections:

- tpcc run
- clickbench run
- tpch run
- tpcds run
- query run

Cleanup

After all necessary testing has been completed, the benchmark's data can be removed from the database using the `clean` command:

```
ydb workload tpcc --path tpcc/10wh clean
ydb workload clickbench --path clickbench/hits clean
ydb workload tpch --path tpch/s1 clean
ydb workload tpcds --path tpcds/s1 clean
ydb workload query --path user/suite1 clean
```

For more details, see the relevant reference sections:

- tpcc clean
- clickbench clean
- tpch clean
- tpcds clean
- query clean

Configuring Time to Live (TTL)

This section contains recipes for configuration of table's TTL with YDB CLI.

Enabling TTL for an existing table

In the example below, the items of the `mytable` table will be deleted an hour after the time set in the `created_at` column:

```
$ ydb -e <endpoint> -d <database> table ttl set --column created_at --expire-after 3600 mytable
```

The example below shows how to use the `modified_at` column with a numeric type (`Uint32`) as a TTL column. The column value is interpreted as the number of seconds since the Unix epoch:

```
$ ydb -e <endpoint> -d <database> table ttl set --column modified_at --expire-after 3600 --unit seconds mytab
le
```

Enabling data eviction to S3-compatible external storage

> **Warning**
>
> Supported only for column-oriented tables. Support for row-oriented tables is currently under development.

To enable data eviction, an external data source object that describes a connection to the external storage is needed. Refer to YQL recipe for examples of creating an external data source.

The example below shows how to enable data eviction by executing a YQL-query from YDB CLI. Rows of the table `mytable` will be moved to the bucket described in the external data source `/Root/s3_cold_data` one hour after the time recorded in the column `created_at` and will be deleted after 24 hours.

```
$ ydb -e <endpoint> -d <database> sql -s '
    ALTER TABLE `mytable` SET (
        TTL =
            Interval("PT1H") TO EXTERNAL DATA SOURCE `/Root/s3_cold_data`,
            Interval("PT24H") DELETE
        ON modified_at AS SECONDS
    );
'
```

Disabling TTL

```
$ ydb -e <endpoint> -d <database> table ttl reset mytable
```

Getting TTL settings

The current TTL settings can be obtained from the table description:

```
$ ydb -e <endpoint> -d <database> scheme describe mytable
```

YQL recipes

This section contains query recipes for various tasks that can be solved with YQL, YDB's SQL dialect.

Table of contents:

- Accessing values inside JSON with YQL
- Modifying JSON with YQL
- Configuring Time to Live (TTL)

See also:

- YQL - Overview
- YDB for Application Developers / Software Engineers

Accessing values inside JSON with YQL

YQL provides two main ways to retrieve values from JSON:

- Using **JSON functions from the SQL standard**. This approach is recommended for simple cases and for teams that are familiar with them from other DBMSs.
- Using **Yson UDF**, list and dict builtins, and lambdas. This approach is more flexible and tightly integrated with YDB's data type system, thus recommended for complex cases.

Below are the recipes that will use the same input JSON to demonstrate how to use each option to check whether a key exists, get a specific value, and retrieve a subtree.

JSON functions

```
$json = @@{
    "friends": [
        {
            "name": "James Holden",
            "age": 35
        },
        {
            "name": "Naomi Nagata",
            "age": 30
        }
    ]
}@@j;

SELECT
    JSON_EXISTS($json, "$.friends[*].name"), -- True
    CAST(JSON_VALUE($json, "$.friends[0].age") AS Int32), -- 35
    JSON_QUERY($json, "$.friends[0]"); -- {"name": "James Holden", "age": 35}
```

`JSON_*` functions expect the `Json` data type as an input to run. In this example, the string literal has the suffix `j`, marking it as `Json`. In tables, data could be stored in either JSON format or as a string representation. To convert data from `String` to `JSON` data type, use the `CAST` function, such as `CAST(my_string AS JSON)`.

Yson UDF

This approach typically combines multiple functions and expressions, so a query might leverage different specific strategies.

Convert the whole JSON to YQL containers

```
$json = @@{
    "friends": [
        {
            "name": "James Holden",
            "age": 35
        },
        {
            "name": "Naomi Nagata",
            "age": 30
        }
    ]
}@@j;

$containers = Yson::ConvertTo($json, Struct<friends:List<Struct<name:String?,age:Int32?>>>);
$has_name = ListAny(
    ListMap($containers.friends, ($friend) -> {
        return $friend.name IS NOT NULL;
    })
);
$get_age = $containers.friends[0].age;
$get_first_friend = Yson::SerializeJson(Yson::From($containers.friends[0]));

SELECT
    $has_name, -- True
    $get_age, -- 35
    $get_first_friend; -- {"name": "James Holden", "age": 35}
```

It is **not** necessary to convert the whole JSON object to a structured combination of containers. Some fields can be omitted if not used, while some subtrees could be left in an unstructured data type like `Json`.

Work with in-memory representation

```
$json = @@{
    "friends": [
        {
            "name": "James Holden",
            "age": 35
        },
        {
            "name": "Naomi Nagata",
            "age": 30
        }
    ]
}@@j;

$has_name = ListAny(
    ListMap(Yson::ConvertToList($json.friends), ($friend) -> {
        return Yson::Contains($friend, "name");
    })
);
$get_age = Yson::ConvertToInt64($json.friends[0].age);
$get_first_friend = Yson::SerializeJson($json.friends[0]);

SELECT
    $has_name, -- True
    $get_age, -- 35
    $get_first_friend; -- {"name": "James Holden", "age": 35}
```

See also

- Modifying JSON with YQL

Modifying JSON with YQL

In memory, YQL operates on immutable values. Thus, when a query needs to change something inside a JSON value, the mindset should be about constructing a new value from pieces of the old one.

This example query takes an input JSON named `$fields`, parses it, substitutes key `a` with 0, drops key `d`, and adds a key `c` with value 3:

```
$fields = '{"a": 1, "b": 2, "d": 4}'j;
$pairs = DictItems(Yson::ConvertToInt64Dict($fields));
$result_pairs = ListExtend(ListNotNull(ListMap($pairs, ($item) -> {
    $item = if ($item.0 == "a", ("a", 0), $item);
    return if ($item.0 == "d", null, $item);
})), [("c", 3)]);
$result_dict = ToDict($result_pairs);
SELECT Yson::SerializeJson(Yson::From($result_dict));
```

- Yson
- Functions for lists
- Functions for dictionaries
- Accessing values inside JSON with YQL

Configuring Time to Live (TTL)

This section contains recipes for configuration of table's TTL with YQL.

Enabling TTL for an existing table

In the example below, the items of the `mytable` table will be deleted an hour after the time set in the `created_at` column:

```
ALTER TABLE `mytable` SET (TTL = Interval("PT1H") ON created_at);
```

> **Tip**
>
> An `Interval` is created from a string literal in ISO 8601 format with some restrictions.

The example below shows how to use the `modified_at` column with a numeric type (`Uint32`) as a TTL column. The column value is interpreted as the number of seconds since the Unix epoch:

```
ALTER TABLE `mytable` SET (TTL = Interval("PT1H") ON modified_at AS SECONDS);
```

Enabling data eviction to S3-compatible external storage

> **Warning**
>
> Supported only for column-oriented tables. Support for row-oriented tables is currently under development.

In the following example, rows of the table `mytable` will be moved to the bucket described in the external data source `/Root/s3_cold_data` one hour after the time recorded in the column `created_at` and will be deleted after 24 hours:

```
ALTER TABLE `mytable` SET (
  TTL =
      Interval("PT1H") TO EXTERNAL DATA SOURCE `/Root/s3_cold_data`,
      Interval("PT24H") DELETE
  ON modified_at AS SECONDS
);
```

> **Warning**
>
> Supported only for column-oriented tables. Support for row-oriented tables is currently under development.

To enable data eviction, an external data source object that describes a connection to the external storage is needed.
In the example below, an external data source `/Root/s3_cold_data` is created. It describes a connection to bucket `test_cold_data` located in Yandex Object Storage with authorization by static access keys provided via secrets `access_key` and `secret_key`.

```
CREATE SECRET access_key WITH (value="...");
CREATE SECRET secret_key WITH (value="...");

CREATE EXTERNAL DATA SOURCE `/Root/s3_cold_data` WITH (
    SOURCE_TYPE="ObjectStorage",
    AUTH_METHOD="AWS",
    LOCATION="http://storage.yandexcloud.net/test_cold_data",
    AWS_ACCESS_KEY_ID_SECRET_PATH="access_key",
    AWS_SECRET_ACCESS_KEY_SECRET_PATH="secret_key",
    AWS_REGION="ru-central1"
)
```

Follow examples below to enable data eviction using an external data source.

In the following example, rows of the table `mytable` will be moved to the bucket described in the external data source `/Root/s3_cold_data` one hour after the time recorded in the column `created_at` and will be deleted after 24 hours:

```
ALTER TABLE `mytable` SET (
    TTL =
        Interval("PT1H") TO EXTERNAL DATA SOURCE `/Root/s3_cold_data`,
        Interval("PT24H") DELETE
    ON modified_at AS SECONDS
);
```

In the following example, rows of the table `mytable` will be moved to buckets `/Root/s3_cold` and `/Root/s3_frozen` one hour and 30 days respectively after the time recorded in the column `created_at`:

```
ALTER TABLE `mytable` SET (
    TTL =
        Interval("PT1H") TO EXTERNAL DATA SOURCE `/Root/s3_cold`,
        Interval("PT30D") TO EXTERNAL DATA SOURCE `/Root/s3_frozen`
    ON modified_at AS SECONDS
);

## Enabling TTL for a newly created table {#enable-for-new-table}

For a newly created table, you can pass TTL settings along with the table description:

```yql
CREATE TABLE `mytable` (
  id Uint64,
  expire_at Timestamp,
  PRIMARY KEY (id)
) WITH (
  TTL = Interval("PT1H") ON expire_at
);
```

Disabling TTL

```
ALTER TABLE `mytable` RESET (TTL);
```
```

Vector index recipes

This section of YDB documentation contains vector index recipes:

- Vector Index — Quick Start

Vector Index — Quick Start

This article will help you quickly get started with vector indexes in YDB using a simple model example.

The article will cover the following steps for working with vector indexes:

- creating a table with vectors;
- populating the table with data;
- building a vector index;
- performing vector search without an index;
- performing vector search with an index.

Step 1. Creating a table with vectors

First, you need to create a table in YDB that will store vectors. This can be done using an SQL query:

```
CREATE TABLE Vectors (
  id Uint64,
  embedding String,
  PRIMARY KEY (id)
);
```

This `Vectors` table has two columns:

- `id` — a unique identifier for each vector
- `embedding` — a vector of real numbers packed into a string

Step 2. Populating the table with data

After creating the table, you should add vectors to it using an `UPSERT INTO` query:

```
UPSERT INTO Vectors(id, embedding)
VALUES
    (1, Untag(Knn::ToBinaryStringFloat([1.f, 1.f, 1.f, 1.f, 1.f]), "FloatVector")),
    (2, Untag(Knn::ToBinaryStringFloat([1.f, 1.f, 1.f, 1.f, 1.25f]), "FloatVector")),
    (3, Untag(Knn::ToBinaryStringFloat([1.f, 1.f, 1.f, 1.f, 1.5f]), "FloatVector")),
    (4, Untag(Knn::ToBinaryStringFloat([-1.f, -1.f, -1.f, -1.f, -1.f]), "FloatVector")),
    (5, Untag(Knn::ToBinaryStringFloat([-2.f, -2.f, -2.f, -2.f, -4.f]), "FloatVector")),
    (6, Untag(Knn::ToBinaryStringFloat([-3.f, -3.f, -3.f, -3.f, -6.f]), "FloatVector"));
```

For a description of the `Knn::ToBinaryStringFloat` function, see KNN.

These examples convert YQL vector literals. When passing vectors as C++ SDK query parameters, serialize them on the client with `NYdb::NValueHelpers::Embedding` (C++ SDK v3.24.0 or later) and declare the parameters as `Bytes`; see the SDK recipe.

Step 3. Building a vector index

To create a vector index `EmbeddingIndex` on the `Vectors` table, use the following command:

```
ALTER TABLE Vectors
ADD INDEX EmbeddingIndex
GLOBAL USING vector_kmeans_tree
ON (embedding)
WITH (
  distance=cosine)
```

This command creates an index of the `vector_kmeans_tree` type. For more information about indexes of this type, see Vector Index Type `vector_kmeans_tree`. In this model example, only the `distance=cosine` parameter is specified — it sets the distance function used by the index. This is an important parameter: the distance function must match the one the embedding model was trained for. The parameters `clusters`, `levels`, and `overlap_clusters` are autodetected and not shown here; if you have a large dataset and want to tune the index, see the detailed parameter reference in Vector index.

For general information about vector indexes, their creation parameters, and current limitations, see the section Vector Indexes.

Step 4. Searching the table without using a vector index

At this step, an exact search for the 3 nearest neighbors for the given vector `[1.f, 1.f, 1.f, 1.f, 4.f]` is performed **without** using an index.

First, the target vector is encoded into a binary representation using `Knn::ToBinaryStringFloat`.

Then, the cosine distance from the `embedding` of each row to the target vector is calculated.

Records are sorted by increasing distance, and the first three (`$K`) records are selected, which are the nearest ones.

```
$K = 3;
$TargetEmbedding = Knn::ToBinaryStringFloat([1.f, 1.f, 1.f, 1.f, 4.f]);

SELECT id, Knn::CosineDistance(embedding, $TargetEmbedding) As CosineDistance
FROM Vectors
ORDER BY Knn::CosineDistance(embedding, $TargetEmbedding)
LIMIT $K;
```

Query execution result:

```
id CosineDistance
3  0.1055728197
2  0.1467181444
1  0.1999999881
```

For detailed information about exact vector search without using vector indexes, see KNN.

Step 5. Searching the table using a vector index

To search for the 3 nearest neighbors of the vector `[1.f, 1.f, 1.f, 1.f, 4.f]` using the `EmbeddingIndex` index that was created in step 3, execute the following query:

```
$K = 3;
$TargetEmbedding = Knn::ToBinaryStringFloat([1.f, 1.f, 1.f, 1.f, 4.f]);

SELECT id, Knn::CosineDistance(embedding, $TargetEmbedding) As CosineDistance
FROM Vectors VIEW EmbeddingIndex
ORDER BY Knn::CosineDistance(embedding, $TargetEmbedding)
LIMIT $K;
```

Note that in this query, after the table name, it is specified that record selection should be performed using the vector index: `FROM Vectors VIEW EmbeddingIndex`.

Query execution result:

```
id CosineDistance
3  0.1055728197
2  0.1467181444
1  0.1999999881
```

Thanks to using the index, searching for the nearest vectors happens significantly faster on large datasets.

Conclusion

This article provides a simple example of working with vector indexes: creating a table with vectors, populating the table with vectors, building a vector index for such a table, and searching for vectors in the table using a vector index or without it.

In the case of a small table, as in this model example, it's impossible to see the difference in query performance. These examples are intended to illustrate the syntax when working with vector indexes.

For more information about vector indexes, see Vector Indexes.

Vector index with a prepared external dataset

This article walks you through working with vector indexes in YDB. It uses an English Wikipedia text dataset (485,859 rows) prepared by the Hugging Face community.

The article covers:

- creating a table for loading data;
- downloading the dataset;
- importing data into the table;
- building the vector index;
- running vector search without the index;
- running vector search with the index.

Prerequisites

To run the examples in this article you need:

- A YDB database with vector index support enabled. For a simple single-node cluster setup, see here. For production deployment options, see here.
- On your machine:
  - The YDB CLI;
  - Python 3;
- Network access from your machine to the hosts where YDB is running.

Step 1. Creating a table

First, create a table in YDB to store the data. You can do this with an SQL query:

```
CREATE TABLE wikipedia (
  id Uint64 NOT NULL,
  title Utf8,
  text Utf8,
  url Utf8,
  wiki_id Uint32,
  views Float,
  paragraph_id Uint32,
  langs Uint32,
  emb Utf8,
  embedding String,
  PRIMARY KEY (id)
);
```

Step 2. Downloading the dataset

Download the dataset from Hugging Face. It contains English Wikipedia texts split into paragraphs, with an embedding vector for each paragraph.

In your working directory, create a file `import_dataset.py` with this Python script:

```
#!/usr/bin/env python
from datasets import load_dataset

# Load the dataset
dataset = load_dataset("Cohere/wikipedia-22-12-simple-embeddings")

# Save it as CSV or another format locally
dataset['train'].to_csv('wikipedia_embeddings_train.csv', index=False)
```

Install the `datasets` package and run the script:

```
pip3 install datasets
python3 import_dataset.py
```

This creates `wikipedia_embeddings_train.csv` in your working directory with the Wikipedia texts and embeddings.

Step 3. Importing data from file into the table

Use the YDB CLI to import the file `wikipedia_embeddings_train.csv` into the table `wikipedia` created in Step 1.

In the command below:

- `<endpoint>` — endpoint of your YDB database
- `<database>` — database path of your YDB database

```
ydb -e <endpoint> -d <database> -v import file csv --path wikipedia --header wikipedia_embeddings_train.csv --timeout 30
```

In this example the test YDB server runs without authentication, so no user credentials are passed to the CLI. For CLI authentication, see here.

The file `wikipedia_embeddings_train.csv` is about 6.26 GB, so the upload may take a while. When it finishes, you can verify that all rows were loaded into the `wikipedia` table from Step 1 with:

```
SELECT COUNT(*) AS row_count FROM wikipedia
```

Query result:

```
row_count
485859
```

For YDB vector indexes, vectors must be in string format (see data types). The embeddings in the imported dataset (stored in the `emb` column) can be converted into the `embedding` column in the required format by running this script on your machine:

```
for (( i=0; i <= 490000; i+=10000 ))
do
echo $i
echo "{\"begin\":$i}" | ydb -e <endpoint> -d <database> table query execute -q 'declare $begin As Int32; UPDATE wikipedia SET embedding = Unwrap(Untag(Knn::ToBinaryStringFloat(Cast(String::SplitToList(String::ReplaceAll(String::RemoveAll(String::RemoveFirst(String::RemoveLast(emb, "]"), "["), "\n"), "  ", " "), " ") AS List<Float>)), "FloatVector")) WHERE id>=$begin AND id < $begin + 10000;'
done
```

Step 4. Building the vector index

To create the vector index `idx_vector` on the `wikipedia` table, run:

```
ALTER TABLE wikipedia
ADD INDEX idx_vector
GLOBAL USING vector_kmeans_tree
ON (embedding)
WITH (
  distance=cosine);
```

This creates a `vector_kmeans_tree` index. For more on this index type, see here.

For general information on vector indexes, creation parameters, and current limitations, see Vector Indexes.

Step 5. Search in the table without using the vector index

This step runs exact search for the 3 nearest neighbors of a given vector **without** using the index. The query vector is assumed to be produced from the search text by an encoder model (e.g. Embed from cohere.com).

First, the target vector is encoded to binary with `Knn::ToBinaryStringFloat`.

Here the search vector is a YQL literal. When passing it as a C++ SDK query parameter, serialize it on the client with `NYdb::NValueHelpers::Embedding` (C++ SDK v3.24.0 or later) and declare the parameter as `Bytes`; see the SDK recipe.

Then cosine distance is computed from each row's `embedding` to the target vector.

Rows are ordered by distance ascending, and the first three (`$K`) rows are returned as the nearest neighbors.

```
$K = 3;
$TargetEmbedding = Knn::ToBinaryStringFloat(Cast([0.1961289,0.51426697,...] AS List<Float>));

SELECT id, title, text, wiki_id, Knn::CosineDistance(embedding, $TargetEmbedding) as CosineDistance
FROM wikipedia VIEW PRIMARY KEY
ORDER BY Knn::CosineDistance(embedding, $TargetEmbedding)
LIMIT $K;
```

For details on exact vector search without vector indexes, see the Knn UDF documentation.

Step 6. Search in the table using the vector index

To search for the 3 nearest neighbors of a given vector using the index `idx_vector` created in Step 4, run:

```
$K = 3;
$TargetEmbedding = Knn::ToBinaryStringFloat(Cast([0.1961289,0.51426697,...] AS List<Float>));

SELECT id, title, text, wiki_id, Knn::CosineDistance(embedding, $TargetEmbedding) as CosineDistance
FROM wikipedia VIEW idx_vector
ORDER BY Knn::CosineDistance(embedding, $TargetEmbedding)
LIMIT $K;
```

The result when using the vector index can differ from the result without it.

Vector indexes provide **approximate** search and are optimized for speed. To improve performance, some data is pruned from consideration, so a few vectors that would have been among the nearest may be missed. Thus approximate search results can differ from exact search results.

Depending on data size, the same query can be orders of magnitude faster with the vector index than without it.

Conclusion

This article demonstrated working with a vector index and an external dataset: creating a table for vectors, loading it from an external dataset, building a vector index on that table, and running vector search with and without the index.

Exact vector search returns the true nearest neighbors but can be expensive, especially on large data. Approximate search returns results much faster with some loss in accuracy, which is often acceptable in practice.

For more on vector indexes, see here.

Fulltext search recipes

This section contains recipes for using fulltext indexes and fulltext search functions.

- Fulltext index - quick start

Fulltext index - quick start

This quick start shows how to create a fulltext index and execute fulltext queries in YDB.

Create a table and a fulltext index

```
CREATE TABLE articles (
  id Uint64,
  title String,
  body String,
  PRIMARY KEY (id)
);

ALTER TABLE articles ADD INDEX ft_idx
  GLOBAL USING fulltext_relevance
  ON (body) COVER (title)
  WITH (tokenizer=standard, use_filter_lowercase=true);
```

Insert sample data

```
UPSERT INTO articles (id, title, body) VALUES
  (1, "Intro",  "Machine learning is a field of AI"),
  (2, "Search", "Fulltext search finds documents by words"),
  (3, "Notes",  "Neural networks are used in machine learning");
```

Filter documents

```
SELECT id, title
FROM articles VIEW ft_idx
WHERE FulltextMatch(body, "machine learning")
LIMIT 20;
```

Query execution result:

```
id title
1  Intro
3  Notes
```

Rank documents

```
SELECT id, title, FulltextScore(body, "machine learning") AS relevance
FROM articles VIEW ft_idx
WHERE FulltextScore(body, "machine learning") > 0
ORDER BY relevance DESC
LIMIT 10;
```

Query execution result:

```
id title relevance
1  Intro  0.8762718444094963
3  Notes  0.8762718444094963
```

- VIEW (Fulltext index)
- Fulltext built-in functions

Recipes for searching JSON documents

This section contains ready-made recipes for using JSON indexes to efficiently select data based on the contents of columns of type `Json` and `JsonDocument`.

The recipes are built around the JSON_EXISTS and JSON_VALUE functions with JsonPath expressions. To guarantee index usage, all examples use explicit access via `VIEW IndexName`.

- JSON index – quick start — minimal scenario: creating a table, an index, inserting data, and basic queries.
- Catalog with nested attributes — example of a product catalog with nested attributes, range conditions, and searching nested arrays.
- Parameterized queries and JsonPath variables — parameterized queries and passing variables to JsonPath via the `PASSING` section.
- Checking field type and path existence — checking the field type and path existence using JsonPath methods.

Before running the examples, make sure that JSON index support is enabled on the cluster.

JSON index – quick start

This guide shows how to create a JSON index and run queries using the JSON_EXISTS and JSON_VALUE functions in YDB.

Create a table and a JSON index

```
CREATE TABLE documents (
    id Uint64,
    payload JsonDocument,
    PRIMARY KEY (id),
    INDEX json_idx GLOBAL USING json ON (payload)
);
```

The column type `JsonDocument` stores JSON in a compact binary format and is preferred for an indexed column. Alternatively, the type `Json` (text representation) can be used.

The primary key of the table must consist of a single column of an integer type (`Uint64`, `Uint32`, `Int64`, or `Int32`) — this is a current limitation of the JSON index implementation.

Add test data

```
UPSERT INTO documents (id, payload) VALUES
    (1, JsonDocument(@@{"user": {"id": 100, "name": "Alice"}, "active": true}@@)),
    (2, JsonDocument(@@{"user": {"id": 101, "name": "Bob"}, "active": false}@@)),
    (3, JsonDocument(@@{"user": {"id": 102, "name": "Charlie"}, "archived": true}@@));
```

Here, the `@@...@@` construct is a multiline string literal, convenient for writing JSON without escaping quotes. The `JsonDocument(...)` function converts text into a value of type `JsonDocument`.

Filter by the presence of a path in the document

The JSON_EXISTS function checks whether a path specified by a JsonPath expression exists in the document.

```
SELECT id
FROM documents VIEW json_idx
WHERE JSON_EXISTS(payload, '$.user.id');
```

Result:

```
id
1
2
3
```

The path token `$.user.id` is used for index search. The index returns the result without scanning the main table.

Selecting rows with a specific document field value

The JSON_VALUE function extracts a scalar value by JsonPath; to use the index, you must specify the return type in the `RETURNING` clause:

```
SELECT id
FROM documents VIEW json_idx
WHERE JSON_VALUE(payload, '$.user.name' RETURNING Utf8) = "Alice"u;
```

Result:

```
id
1
```

When checking equality, the token «path + value» (`$.user.name = "Alice"`) is placed into the index, which ensures the highest selectivity.

Combination of conditions

Multiple calls `JSON_EXISTS` / `JSON_VALUE` on a single indexed JSON column can be combined using the `AND` and `OR` operators:

```
SELECT id
FROM documents VIEW json_idx
WHERE JSON_EXISTS(payload, '$.user.id')
  AND JSON_VALUE(payload, '$.active' RETURNING Bool);
```

Result:

```
id
1
```

See also

- JSON indexes — a complete overview of capabilities and limitations.
- VIEW (JSON index) — query syntax through `VIEW`.
- INDEX (CREATE TABLE) — syntax for creating a JSON index.

- Catalog with nested attributes — example of a product catalog with nested attributes.

Catalog with nested attributes

This recipe shows how to use a JSON index to speed up access to a product catalog where product characteristics are stored as a JSON document with an arbitrary set of fields. This schema is convenient when:

- The set of product attributes is unknown in advance or differs for different categories.
- Adding new attributes via `ALTER TABLE ADD COLUMN` is undesirable.
- You need to efficiently filter products by various combinations of attributes.

A JSON index enables efficient retrieval by any path and value inside a JSON document without a full table scan.

Create a table and index

```
CREATE TABLE products (
    sku_id Uint64,
    attrs JsonDocument,
    PRIMARY KEY (sku_id),
    INDEX attrs_json_idx GLOBAL USING json ON (attrs)
);
```

In this schema:

- `sku_id` — numeric product identifier.
- `attrs` — product attributes in `JsonDocument` format. Storing as `JsonDocument` saves space and speeds up deserialization compared to `Json`.
- `attrs_json_idx` — JSON index on column `attrs`. It is updated synchronously together with the main table.

Load test data

```
UPSERT INTO products (sku_id, attrs) VALUES
    (10, JsonDocument(@@{
        "brand": "ACME",
        "price": 49.90,
        "category": "tools",
        "warehouses": [{"id": 1, "stock": 12}, {"id": 2, "stock": 0}]
    }@@)),
    (11, JsonDocument(@@{
        "brand": "ACME",
        "price": 199.00,
        "category": "electronics",
        "warehouses": [{"id": 1, "stock": 3}]
    }@@)),
    (12, JsonDocument(@@{
        "brand": "Globex",
        "price": 25.00,
        "category": "tools",
        "warehouses": [{"id": 2, "stock": 0}]
    }@@));
```

Filter by brand and price range

```
SELECT sku_id, attrs
FROM products VIEW attrs_json_idx
WHERE JSON_VALUE(attrs, '$.brand' RETURNING Utf8) = "ACME"u
  AND JSON_VALUE(attrs, '$.price' RETURNING Double) BETWEEN 10.0 AND 100.0;
```

What happens:

- For the `$.brand = "ACME"` condition, the token «path + value» goes into the index — this gives an exact match and maximum selectivity.
- For the `BETWEEN 10.0 AND 100.0` condition, only the path token `$.price` goes into the index. This narrows the set of rows to those where the `price` field is present, after which the query execution engine checks the range with an exact comparison (post-filter).
- The conditions are combined via `AND` — this allows the index to be used to check both fragments at once, resulting in minimal index reads.

Result:

```
sku_id attrs
10     {"brand":"ACME","price":49.9,...}
```

Search by nested array

JsonPath supports accessing array elements and filters within the path. For example, you can find products that have stock in at least one warehouse:

```
SELECT sku_id
FROM products VIEW attrs_json_idx
WHERE JSON_EXISTS(attrs, '$.warehouses ? (@.stock > 0)');
```

For index search, the path token `$.warehouses.stock` is used, and the `@.stock > 0` condition is checked by a post-filter on each found record. This is efficient when the corresponding field is present in a relatively small portion of documents.

Result:

```
sku_id
10
11
```

Search by category and attribute presence

Conditions can be combined with any `AND` and `OR` operators. Search for products in category `tools` that have the `price` field specified:

```
SELECT sku_id
FROM products VIEW attrs_json_idx
WHERE JSON_VALUE(attrs, '$.category' RETURNING Utf8) = "tools"u
  AND JSON_EXISTS(attrs, '$.price');
```

Result:

```
sku_id
10
12
```

- Parameterized queries and JsonPath variables — parameterized versions of the same queries.

Parameterized queries and JsonPath variables

In most applications, query input data is not substituted into SQL text but is passed via parameters. Typical use cases for parameters when working with JSON indexes:

1. direct comparison of the result of `JSON_VALUE` with a parameter.
2. checking whether the result is in a list of values using the `IN` expression.
3. passing a parameter to a JsonPath expression via the `PASSING` clause.

Prerequisites

Below is an example of a table, a JSON index, and data population.

```
CREATE TABLE documents (
    id Uint64,
    payload JsonDocument,
    PRIMARY KEY (id),
    INDEX json_idx GLOBAL USING json ON (payload)
);

UPSERT INTO documents (id, payload) VALUES
    (1, JsonDocument(@@{
        "owner_id": 100,
        "tag": "active",
        "archived": false,
        "content": {"x": 1, "y": 1}
    }@@)),
    (2, JsonDocument(@@{
        "owner_id": 100,
        "tag": "draft",
        "archived": false,
        "content": {"x": 1, "y": 2}
    }@@)),
    (3, JsonDocument(@@{
        "owner_id": 101,
        "tag": "active",
        "archived": true,
        "content": {"x": 2, "y": 1}
    }@@)),
    (4, JsonDocument(@@{
        "owner_id": 102,
        "tag": "pending",
        "archived": false,
        "content": {"x": 2, "y": 2}
    }@@));
```

Direct comparison with a parameter

The most common case is that the parameter is substituted as the right operand of the comparison, and the left operand is a call to `JSON_VALUE` with an explicit `RETURNING`:

```
DECLARE $owner_id AS Int64;

SELECT id, payload
FROM documents VIEW json_idx
WHERE JSON_VALUE(payload, '$.owner_id' RETURNING Int64) = $owner_id
  AND JSON_EXISTS(payload, '$.archived ? (@ == false)');
```

The index receives a token «path + value» (`$.owner_id = $owner_id`) — the parameter is treated as a regular value. This allows performing a query with the same selectivity as when comparing with a literal.

Running with `$owner_id = 100` returns rows `1` and `2`.

Search by a list of values

To search by multiple values of a single field, you can use `IN`:

```
DECLARE $tags AS List<Utf8>;

SELECT id
FROM documents VIEW json_idx
WHERE JSON_VALUE(payload, '$.tag' RETURNING Utf8) IN $tags;
```

The behavior of the index differs depending on whether it is a literal or a parameter:

- `IN ("active"u, "pending"u)` — a list of literals is converted into `OR` of several «path + value» tokens, one for each value in the list.
- `IN $tags` — for each parameter value during query execution, a «path + value» token is formed (`$.tag` + value from the list). At the compilation stage, the parameter values are not yet known, so in the query plan (`EXPLAIN`) such a condition is displayed as a «path + parameter» pair (`{"path": "$.tag", "param": "$tags"}`).

Any collection of scalar values can serve as a parameter for `IN`: `List<T>`, `Tuple<T, ...>`, `Dict<K, V>`, or `Set<T>`.

Running with `$tags = ["active"u, "pending"u]` returns rows `1`, `3`, and `4`.

Parameters inside JsonPath (PASSING)

If a parameter must be used inside a JsonPath filter (`? (...)`), it is passed in the `PASSING` clause:

```
DECLARE $min_stock AS Int64;

SELECT id
FROM documents VIEW json_idx
WHERE JSON_EXISTS(
    payload,
    '$.content ? (@.y > $threshold)'
    PASSING $min_stock AS threshold
);
```

For index search, the path token `$.content.y` is used, and the condition `@.y > $threshold` is checked by a post-filter.

Similarly, `PASSING` works in `JSON_VALUE`:

```
DECLARE $v AS Int64;

SELECT id
FROM documents VIEW json_idx
WHERE JSON_VALUE(
    payload,
    '$.content ? (@.y == $val)'
    PASSING $v AS val
    RETURNING Int64
) = 10;
```

Supported parameter types

For all three methods, parameters with the following types are supported: `Int8` … `Int64`, `Uint8` … `Uint64`, `Float`, `Double`, `Bytes` (`String`), `Text` (`Utf8`), `Bool`. Optional types (`Optional<T>`) are not supported in parameters.

For more details about types, see JSON_VALUE.

See also

- JSON index – quick start — basic use case for a JSON index.
- Passing parameters to JSON index predicates — detailed description of all options.
- JsonPath — JsonPath language syntax.

Checking field type and path existence

This recipe shows how a JSON index is used to check document structure: the presence of a specific path, the type of value at the path, etc. These tasks are common when working with heterogeneous JSON documents where some fields are optional or may have different types.

Prerequisites

```
CREATE TABLE documents (
    id Uint64,
    payload JsonDocument,
    PRIMARY KEY (id),
    INDEX json_idx GLOBAL USING json ON (payload)
);

UPSERT INTO documents (id, payload) VALUES
    (1, JsonDocument(@@{"archived": false, "value": 1,    "data": [1, 2, 3]}@@)),
    (2, JsonDocument(@@{"archived": false, "value": 2,    "data": "plain text"}@@)),
    (3, JsonDocument(@@{"archived": true,  "value": 3,    "data": {"nested": true}}@@)),
    (4, JsonDocument(@@{"archived": false, "value": null, "meta": "no data field"}@@));
```

Find documents where a field contains an array

The JsonPath method `.type()` returns a string name of the value type at the specified path. This allows filtering documents by content type:

```
SELECT id
FROM documents VIEW json_idx
WHERE JSON_VALUE(payload, '$.data.type()' RETURNING Utf8) = "array"u;
```

The path token `$.data` is added to the index — the method `.type()` completes the path token construction. The exact check of the string value `"array"` is performed by a post-filter.

Result:

```
id
1
```

The full list of values returned by the method `.type()` is given in the JsonPath syntax description.

Find documents where a field is a non-empty array

The method `.size()` returns the number of array elements (or 1 for a scalar, 0 for a missing path). In combination with a type filter:

```
SELECT id
FROM documents VIEW json_idx
WHERE JSON_VALUE(payload, '$.data.type()' RETURNING Utf8) = "array"u
  AND JSON_VALUE(payload, '$.data.size()' RETURNING Int64) > 0;
```

Both fragments are indexed by the corresponding paths, and the exact values are checked by a post-filter. Result: `id = 1`.

Find documents with value `false` or `null`

To check for "value equals `false`" or "value equals `null`", use JsonPath inside `JSON_EXISTS`, not `JSON_VALUE(...) IS NULL`:

```
-- The value of the 'archived' field is false
SELECT id
FROM documents VIEW json_idx
WHERE JSON_EXISTS(payload, '$.archived ? (@ == false)');

-- The value of the 'value' field is null
SELECT id
FROM documents VIEW json_idx
WHERE JSON_EXISTS(payload, '$.value ? (@ == null)');
```

The index search operation includes the path `$.archived` (or `$.value`) and the values `false` or `null`, respectively.

> **Note**
>
> The above conditions select documents where the specified attribute is explicitly set to false or null. Checking for the absence of an attribute cannot be done using a JSON index.

Local index recipes

Practical examples of local indexes.

- Bloom skip index quickstart
- Quick start with the min_max index

Bloom skip index quickstart

Column-oriented (OLAP) table: bloom_filter

Below is a minimal example: a column-oriented table with a primary key and a local `bloom_filter` index on a column that is frequently used in filters.

```
CREATE TABLE events (
    id Uint64 NOT NULL,
    resource_id Utf8 NOT NULL,
    payload String,
    message Utf8,
    PRIMARY KEY (id),
    INDEX idx_res LOCAL USING bloom_filter
        ON (resource_id)
        WITH (false_positive_probability = 0.01)
)
WITH (
    STORE = COLUMN
);
```

Extending the example: n-gram index

You can add `bloom_ngram_filter` on a string column to the same table from the example above (column-oriented tables):

```
ALTER TABLE events
  ADD INDEX idx_msg LOCAL USING bloom_ngram_filter
  ON (message)
  WITH (
    ngram_size = 3,
    false_positive_probability = 0.01,
    case_sensitive = true
  );
```

Queries and the effect

After you load data, selective queries that filter on indexed columns may read less data: while scanning storage, the Bloom skip index skips fragments that cannot contain the requested value (compared to reading the full column without this filter).

Sample data and queries for the column-oriented table above:

```
INSERT INTO events (id, resource_id, payload, message) VALUES
    (1, "res-1", "{}", "started"),
    (2, "res-42", "{}", "error: timeout"),
    (3, "res-2", "{}", "done");
```

Equality on the column protected by `bloom_filter` — the engine can prune irrelevant fragments when reading `resource_id` and related columns:

```
SELECT id, message
FROM events
WHERE resource_id = "res-42";
```

Substring search on the column with `bloom_ngram_filter` — the n-gram index helps drop fragments that cannot contain matching n-grams in `message`:

```
SELECT id, message
FROM events
WHERE message LIKE '%timeout%';
```

Row-oriented (OLTP) table: prefix bloom filter

On a row-oriented table, a `bloom_filter` index is built over a left prefix of the primary key. The indexed columns must be a contiguous leading subset of the primary key columns:

```
CREATE TABLE orders (
    customer_id Utf8 NOT NULL,
    order_id Utf8 NOT NULL,
    amount Decimal(10,2),
    PRIMARY KEY (customer_id, order_id),
    -- Prefix bloom filter on the first key column
    INDEX idx_customer LOCAL USING bloom_filter
        ON (customer_id)
        WITH (false_positive_probability = 0.001),
    -- Prefix bloom filter on the full primary key
    INDEX idx_full_key LOCAL USING bloom_filter
        ON (customer_id, order_id)
);
```

Point lookups and range scans that constrain the leading key columns can skip irrelevant data fragments. A query that filters on `customer_id` only uses the prefix bloom filter `idx_customer`:

```
SELECT amount FROM orders WHERE customer_id = "cust-42";
```

A query that filters on the full primary key uses `idx_full_key`:

```
SELECT amount FROM orders WHERE customer_id = "cust-42" AND order_id = "ord-1001";
```

How to verify index effectiveness

To check that the Bloom skip index actually helps, run the same selective query on a table with enough data before and after creating the index and compare execution time.

Further reading:

- Details and limitations: Bloom skip indexes
- Parameter tuning: Parameter tuning
- Full syntax: ALTER TABLE ADD INDEX

Quick start with the min_max index

Creating a table with the min_max index

Below is a minimal example: a columnar table with a primary key and a local index of type `min_max` on columns that are often used in filters.

```
CREATE TABLE events (
    id Uint64 NOT NULL,
    created_at Timestamp,
    level Int32,
    resource_id Utf8,
    PRIMARY KEY (id),
    INDEX idx_created_at LOCAL USING min_max
        ON (created_at),
    INDEX idx_level LOCAL USING min_max
        ON (level)
)
WITH (
    STORE = COLUMN
);
```

Queries and effect

After data is loaded, selective queries with filters on indexed columns can read less data: during a storage scan, the min_max index skips fragments whose value range cannot contain matching rows.

Example data and queries for the table above:

```
INSERT INTO events (id, created_at, level, resource_id) VALUES
    (1, Timestamp("2024-01-01T00:00:00.000000Z"), 1, "res-1"),
    (2, Timestamp("2024-01-01T00:01:00.000000Z"), 3, "res-42"),
    (3, Timestamp("2024-01-02T00:00:00.000000Z"), 5, "res-2");
```

Range filter on the timestamp column:

```
SELECT id, resource_id
FROM events
WHERE created_at >= Timestamp("2024-01-01T00:00:00.000000Z")
  AND created_at <  Timestamp("2024-01-02T00:00:00.000000Z");
```

Range filter on the numeric column:

```
SELECT id, resource_id
FROM events
WHERE level BETWEEN 2 AND 4;
```

How to check index efficiency

To verify that the min_max index really helps, run the same selective query on a table with a sufficient amount of data before and after creating the index and compare the execution time.

Additionally:

- Details and limitations: min_max index
- Full syntax: ALTER TABLE ADD INDEX

Topic-to-Table Data Transfer Recipes

This section provides practical examples for setting up a transfer from topics to tables.

Contents:

- Transfer — quick start
- Transfer — streaming NGINX access logs to a table

Transfer — quick start

This guide helps you get started with transfer in YDB using a basic example.

This guide covers the following steps for working with transfers:

- creating a topic, for the transfer to read from;
- creating a table, for the transfer to write data to;
- creating the transfer;
- populating the topic with data;
- verifying the table contents.

Step 1. Create a topic

First, you need to create a topic in YDB that the transfer will read data from. You can do this using a YQL query:

```
CREATE TOPIC `transfer_recipe/source_topic`;
```

The `transfer_recipe/source_topic` topic lets you transfer any unstructured data.

Step 2. Create a table

After creating the topic, you need to create a table that will receive data from the `source_topic` topic. You can do this using a YQL query:

```
CREATE TABLE `transfer_recipe/target_table` (
  partition Uint32 NOT NULL,
  offset Uint64 NOT NULL,
  data String,
  PRIMARY KEY (partition, offset)
);
```

The `transfer_recipe/target_table` table has three columns:

- `partition` — the ID of the topic partition the message was received from;
- `offset` — the sequence number that identifies the message within its partition;
- `data` — the message body.

Step 3. Create a transfer

After creating the topic and the table, you need to create a data transfer that will move messages from the topic to the table. You can do this using a YQL query:

```
$transformation_lambda = ($msg) -> {
    return [
        <|
            partition: $msg._partition,
            offset: $msg._offset,
            data: $msg._data
        |>
    ];
};

CREATE TRANSFER `transfer_recipe/example_transfer`
  FROM `transfer_recipe/source_topic` TO `transfer_recipe/target_table`
  USING $transformation_lambda;
```

In this example:

- `$transformation_lambda` - a transformation rule for converting a topic message into table columns. In this case, the topic message is transferred to the table without any changes. To learn more about configuring transformation rules, see the documentation;
- `$msg` - a variable that contains the topic message being processed.

Step 4. Populate the topic with data

After creating the transfer, you can write messages to the topic, for example, using the YDB CLI.

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

```
echo "Message 1" | ydb --profile quickstart topic write 'transfer_recipe/source_topic'
echo "Message 2" | ydb --profile quickstart topic write 'transfer_recipe/source_topic'
echo "Message 3" | ydb --profile quickstart topic write 'transfer_recipe/source_topic'
```

Step 5. Verify the table contents

After writing messages to the `source_topic` topic, records will appear in the `transfer_recipe/target_table` table after a short delay. You can verify this using a YQL query:

```
SELECT *
FROM `transfer_recipe/target_table`;
```

Query result:

partition	offset	data
0	0	Message 1
0	1	Message 2
0	2	Message 3

Rows are not added to the table for each message received from the topic; instead, they are buffered and inserted in batches. By default, data is written to the table every 60 seconds or when the volume of accumulated data reaches 8 MB. These parameters can be explicitly configured when creating a transfer or modified later.

Conclusion

This guide provides a basic example of working with a transfer: creating a topic, table, and transfer, writing data to the topic, and verifying the result.

These examples are designed to illustrate the syntax for working with transfers. For a more realistic example, see the article that describes how to stream NGINX access logs.

Transfer — streaming NGINX access logs to a table

This guide explains how to set up streaming of NGINX access logs to a YDB table for further analysis. It covers the default NGINX access log format. To learn more about the NGINX log format and how to configure it, see the NGINX documentation.

The default NGINX access log format is as follows:

```
$remote_addr - $remote_user [$time_local] "$request" $status $body_bytes_sent "$http_referer" "$http_user_agent"
```

Example:

```
::1 - - [01/Sep/2025:15:02:47 +0500] "GET /favicon.ico HTTP/1.1" 404 181 "-" "Mozilla/5.0 (X11; Linux x86_64) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/136.0.0.0 YaBrowser/25.6.0.0 Safari/537.36"
::1 - - [01/Sep/2025:15:02:51 +0500] "GET / HTTP/1.1" 200 409 "-" "Mozilla/5.0 (X11; Linux x86_64) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/136.0.0.0 YaBrowser/25.6.0.0 Safari/537.36"
::1 - - [01/Sep/2025:15:02:51 +0500] "GET /favicon.ico HTTP/1.1" 404 181 "http://localhost/" "Mozilla/5.0 (X11; Linux x86_64) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/136.0.0.0 YaBrowser/25.6.0.0 Safari/537.36"
```

This guide covers the following steps:

- creating a table to write the data to;
- creating the transfer;
- verifying the table contents.

Prerequisites

To complete the examples in this guide, it needs:

- A YDB cluster, version 25.2 or later. For instructions on how to install a single-node YDB cluster, see the guide. For recommendations on deploying YDB for production use, see this guide.
- An installed NGINX HTTP server with access logging enabled, or access to NGINX access logs from another server.
- A configured process to stream NGINX access logs from a file to the `transfer_recipe/access_log_topic` topic. For example, you can use Kafka Connect configured to stream data from a file to a topic.

Step 1. Create a table

Create a table that will receive data from the `transfer_recipe/access_log_topic` topic. You can do this using a YQL query:

```
CREATE TABLE `transfer_recipe/access_log` (
  partition Uint32 NOT NULL,
  offset Uint64 NOT NULL,
  line Uint64 NOT NULL,
  remote_addr String,
  remote_user String,
  time_local Timestamp,
  request_method String,
  request_path String,
  request_protocol String,
  status Uint32,
  body_bytes_sent Uint64,
  http_referer String,
  http_user_agent Utf8,
  PRIMARY KEY (partition, offset, line)
);
```

The `transfer_recipe/access_log` table has three service columns:

- `partition` — the ID of the topic partition the message was received from;
- `offset` — the sequence number that identifies the message within its partition;
- `line` — the sequence number of the log line within the message.

Together the `partition`, `offset` and `line` columns uniquely identify each line from the access log file.

If you need to store access log data for a limited time, you can configure the automatic deletion of old table rows. For example, to set a retention period of 24 hours, you can use a YQL query:

```
ALTER TABLE `transfer_recipe/access_log` SET (TTL = Interval("PT24H") ON time_local);
```

Step 2. Create a transfer

After creating the topic and the table, you need to create a data transfer that will move messages from the topic to the table. You can do this using a YQL query:

```
$transformation_lambda = ($msg) -> {
    -- Function to convert a log line into a table row
    $line_lambda = ($line) -> {
        -- First, split the line by the " (double quote) character to separate strings that may contain space
s.
        -- The strings themselves cannot contain double quotes; instead, they are replaced with the \x22 char
acter sequence.
        $parts = String::SplitToList($line.1, '"');
        -- Split each resulting part that isn't a quoted string by spaces.
        $info_parts = String::SplitToList($parts[0], " ");
        $request_parts = String::SplitToList($parts[1], " ");
        $response_parts = String::SplitToList($parts[2], " ");
        -- Convert the date to the Datetime type
        $dateParser = DateTime::Parse("%d/%b/%Y:%H:%M:%S");
        $date = $dateParser(SUBSTRING($info_parts[3], 1));

        -- Return a structure where each named field corresponds to a table column.
        -- Important: The data types of the named fields must match the data types of the table columns. For
example, if a column is of type Uint32,
        -- the value of the named field must also be of type Uint32. Otherwise, an explicit CAST is required.
        -- Values for NOT NULL columns must be extracted from optional types using the Unwrap function.
        return <|
            partition: $msg._partition,
            offset: $msg._offset,
            line: $line.0,
            remote_addr: $info_parts[0],
            remote_user: $info_parts[2],
            time_local: DateTime::MakeTimestamp($date),
            request_method: $request_parts[0],
            request_path: $request_parts[1],
            request_protocol: $request_parts[2],
            status: CAST($response_parts[1] AS Uint32),
            body_bytes_sent: CAST($response_parts[2] AS Uint64),
            http_referer: $parts[3],
            http_user_agent: CAST(String::CgiUnescape($parts[5]) AS Utf8) -- Explicitly cast to Utf8, because
the http_user_agent column is of type Utf8, not String
        |>;
    };

    $split = String::SplitToList($msg._data, "\n"); -- If a message contains multiple log lines, split it int
o individual lines
    $lines = ListFilter($split, ($line) -> { -- Filter out empty lines, which can be caused by a trailing \n
character
        return LENGTH($line) > 0;
    });

    -- Convert each access log line into a table row
    return ListMap(ListEnumerate($lines), $line_lambda);
};

CREATE TRANSFER `transfer_recipe/access_log_transfer`
  FROM `transfer_recipe/access_log_topic` TO `transfer_recipe/access_log`
  USING $transformation_lambda;
```

In this example:

- `$transformation_lambda` - a transformation rule for converting a topic message into table columns. Each access log line within the message is processed individually using `line_transformation_lambda`;
- `$line_lambda` - a transformation rule for converting a single access log line into a table row;
- `$msg` - variable that contains the topic message being processed.

Step 3. Verify the table contents

After writing messages to the `transfer_recipe/access_log_topic` topic, records will appear in the `transfer_recipe/access_log` table after a short delay. You can verify this using a YQL query:

```
SELECT *
FROM `transfer_recipe/access_log`;
```

Query result:

#	partition	offset	line	remote_addr	remote_user	time_local	request_method	request_path	request_protocol	status	bo
1	0	2	0	::1	-	2025-09-01T15:02:51.000000Z	GET	/favicon.ico	HTTP/1.1	404	18

2	0	1	0	::1	-	2025-09-01T15:02:51.000000Z	GET	/	HTTP/1.1	200	40
3	0	0	0	::1	-	2025-09-01T15:02:47.000000Z	GET	/favicon.ico	HTTP/1.1	404	18

Rows are not added to the table for each message received from the topic; instead, they are buffered and inserted in batches. By default, data is written to the table every 60 seconds or when the volume of accumulated data reaches 8 MB. These parameters can be explicitly configured when creating a transfer or modified later.

Conclusion

This guide demonstrates how to stream NGINX access logs to a YDB table. You can process logs of any other text format in a similar way: create a table to store the required data from the log, and write a lambda function to correctly transform the log lines into table rows.

Backup and restore via NFS

This recipe describes preparing NFS for the server commands `export nfs` and `import nfs`: cluster requirements, access rights, step-by-step configuration of the NFS server and clients, feature flags, performance, and diagnostics. See the reference for command syntax: export to NFS, import from NFS.

Prerequisites

The `export nfs` / `import nfs` operations are performed by **server processes** YDB, not by the CLI client. This means the file system must be accessible from each cluster node:

- The NFS directory must be mounted on **all nodes** of the YDB cluster at the same absolute path.
- The YDB process must have **write** permissions for export and **read** permissions for import to this directory.
- The `--fs-path` path must be absolute. Relative paths, paths containing `..` or `.`, and paths with null bytes will be rejected by the server.
- The functionality must be enabled using the feature flag `enable_fs_backups`.

> **Warning**
>
> This functionality is compatible with the NFSv4 network file system protocol.

Access rights

File operations are performed by server processes YDB, not by the CLI client. Therefore, permissions to the NFS directory must be granted to the OS user under which the `ydbd` process runs.

POSIX permissions:

- For **export** (writing files): `rwx` on the directory (read for traversal, write for creating files and subdirectories, execute for navigation) and `rw` on files.
- For **import** (reading files): `rx` on the directory (read for traversal, execute for navigation) and `r` on files.

NFSv4 ACL:

NFSv4 uses an extended permission model instead of POSIX `rwx`. The same letter in an NFSv4 ACE has different meanings for files and directories:

Letter	For files	For directories
`r`	`read-data` — read content	`list-directory` — view content
`w`	`write-data` — write data	`create-file` — create files
`a`	`append-data` — append data	`create-subdirectory` — create subdirectories
`x`	`execute` — execute	`change-directory` — navigate
`D`	—	`delete-child` — delete child objects
`t`	`read-attributes`	`read-attributes`

Permissions on the NFS directory for **export** (creating files and subdirectories):

- On the directory itself: `w` (create-file), `a` (create-subdirectory), `x` (change-directory), `t` (read-attributes), `D` (delete-child).
- On created files: `w` (write-data), `a` (append-data), `t` (read-attributes).

Permissions on the NFS directory for **import** (reading files):

- On the directory itself: `r` (list-directory), `x` (change-directory), `t` (read-attributes).
- On files: `r` (read-data), `t` (read-attributes).

Since files are created by the `ydbd` process during export, permissions on them cannot be set in advance. In NFSv4, **ACE inheritance** is used for this — the `f` (file-inherit) and `d` (directory-inherit) flags on the parent directory's ACE. When a new file or subdirectory is created, the ACE with these flags is automatically copied to the new object.

Step-by-step setup NFS-server and clients

Below are instructions for configuring the NFS server and YDB client nodes for two permission management options: standard POSIX permissions and extended NFSv4 ACL.

Option 1: POSIX permissions

Configuring the NFS server

1. Install the NFS server package:

```
sudo apt install nfs-kernel-server
```

2. Create a directory for export and assign the owner:

```
sudo mkdir -p /mnt/ydb-backup
sudo chown ydb:ydb /mnt/ydb-backup
sudo chmod 755 /mnt/ydb-backup
```

Options of the `chmod` command:

- `7` (rwx) — the owner (`ydb`) can read, write, and enter the directory.
- `5` (r-x) — the group and others can read and enter, but not write.

3. Add the directory to `/etc/exports`:

   ```
   /mnt/ydb-backup ydb-node-*.example.com(rw,sync,root_squash)
   ```

   Export options:

   - `rw` — allow read and write.
   - `sync` — synchronous write (data is written to disk before acknowledging the client).
   - `root_squash` — map `root` on the client to an anonymous user.

4. Apply the changes and start the NFS server:

   ```
   sudo exportfs -arv
   sudo systemctl enable --now nfs-server
   ```

   Options of `exportfs`:

   - `-a` — export all directories from `/etc/exports`.
   - `-r` — re-export all directories (synchronization with `/etc/exports`).
   - `-v` — verbose output.

Configuring clients (YDB nodes)

1. Install the NFS client package:

   ```
   sudo apt install nfs-common
   ```

2. Create a mount point:

   ```
   sudo mkdir -p /mnt/ydb-backup
   ```

3. Mount the NFS directory:

   ```
   sudo mount -t nfs4 -o rw nfs-server.example.com:/mnt/ydb-backup /mnt/ydb-backup
   ```

   Mount options:

   - `-t nfs4` — NFSv4 file system type.
   - `-o rw` — mount with read and write permissions.

   In this example, the host server does not belong to the YDB cluster, but backup and restore will work correctly if one of the cluster hosts is designated as the NFS server.

4. To enable automatic mounting at boot, add a line to `/etc/fstab`:

   ```
   nfs-server.example.com:/mnt/ydb-backup /mnt/ydb-backup nfs4 rw,hard,timeo=600,retrans=2,_netdev 0 0
   ```

   `fstab` options:

   - `rw` — read and write.
   - `hard` — retry requests indefinitely if the server is unavailable (do not lose data).
   - `timeo=600` — request timeout in tenths of a second (60 seconds).
   - `retrans=2` — number of retries before reporting an error.
   - `_netdev` — mount only after network initialization.

Verification

On the server (or any client), create a test file as user `ydb`:

```
sudo -u ydb touch /mnt/ydb-backup/test-file
```

On all client nodes, verify that the file is visible:

```
sudo -u ydb ls /mnt/ydb-backup/test-file
```

After verification, delete the test file:

```
sudo -u ydb rm /mnt/ydb-backup/test-file
```

Option 2: NFSv4 ACL

NFSv4 ACLs allow you to set more granular access permissions and configure permission inheritance for newly created files and directories.

Configuring the NFS server

1. Install the NFS server package and utilities for working with NFSv4 ACLs:

   ```
   sudo apt install nfs-kernel-server nfs4-acl-tools
   ```

2. Create a directory for export:

```
sudo mkdir -p /mnt/ydb-backup-server
```

3. Add the directory to `/etc/exports`:

```
/mnt/ydb-backup-server ydb-node-*.example.com(rw,sync,no_subtree_check,root_squash)
```

4. Apply the changes:

```
sudo exportfs -arv
sudo systemctl enable --now nfs-server
```

Configuring clients (YDB nodes)

Unlike POSIX permissions, which are set on the NFS server, NFSv4 ACLs are configured on each client after mounting the directory. If the NFS server is also a YDB cluster node, all the steps described below must be performed on it.

1. Install the NFS client packages and utilities for working with NFSv4 ACLs:

```
sudo apt install nfs-common nfs4-acl-tools
```

2. Create a mount point:

```
sudo mkdir -p /mnt/ydb-backup
```

3. Mount the NFS directory using the NFSv4 protocol:

```
sudo mount -t nfs4 -o rw nfs-server.example.com:/mnt/ydb-backup /mnt/ydb-backup
```

   Options:

   - `-t nfs4` — explicitly specify the NFSv4 protocol (required for correct ACL operation).
   - `-o rw` — mount with read and write permissions.

4. To enable automatic mounting, add a line to `/etc/fstab`:

```
nfs-server.example.com:/mnt/ydb-backup-server /mnt/ydb-backup nfs4 rw,hard,timeo=600,retrans=2,_netde
v 0 0
```

5. Determine the UID of user `ydb`:

```
id -u ydb
```

   Example output: `1871`

6. Configure NFSv4 ACLs on the directory:

```
sudo nfs4_setfacl -s A::<uid>:rwaxtD,A:fi:OWNER@:rwat,A:di:OWNER@:rwaxtD /mnt/ydb-backup
```

   ACE structure (`A:flags:who:permissions`):

   - `A` — ACE type: Allow.
   - Inheritance flags:
     - `f` (file-inherit) — inherit to created files.
     - `d` (directory-inherit) — inherit to created subdirectories.
     - `i` (inherit-only) — apply only to descendants, not to the directory itself.
   - `who` — who the permissions are granted to:
     - `1871` — UID of user `ydb`.
     - `OWNER@` — object owner.
   - Permissions:
     - `r` — read-data / list-directory.
     - `w` — write-data / create-file.
     - `a` — append-data / create-subdirectory.
     - `t` — read-attributes.
     - `D` — delete-child.

   This command sets:

   - Permissions for user `ydb` on the directory itself.
   - Inherited permissions for files and subdirectories (`fi` , `di`), which will apply only to descendants.
   - Owner permissions (`OWNER@`) with inheritance to files and directories.

Verification

Check the configured ACLs:

```
nfs4_getfacl /mnt/ydb-backup
```

Create a test file as user `ydb`:

```
sudo -u ydb touch /mnt/ydb-backup/test-file
```

Verify that the file inherited the ACL:

```
nfs4_getfacl /mnt/ydb-backup/test-file
```

On all client nodes, check access:

```
sudo -u ydb ls /mnt/ydb-backup/test-file
```

After verification, delete the test file:

```
sudo -u ydb rm /mnt/ydb-backup/test-file
```

Feature flags

To use export and import via NFS, you need to enable the `enable_fs_backups` feature flag in the cluster configuration. By default, this flag is **disabled**.

Performance configuration

Two mechanisms affect the performance of export and import operations via NFS: the **resource broker** (manages the parallelism of scan and data load tasks) and the **actor system IO pool** (handles file write and read operations).

Resource broker

Export and import via NFS use the same resource broker queues as S3: `queue_backup` for export and `queue_restore` for import. Increasing the limits speeds up operations but increases CPU load. Default values and configuration method are described in the resource_broker_config section.

Actor system IO pool

File operations (write during export, read during import) are performed by actors in the pool of the actor system. By default, this pool contains `1` thread. Since file system operations are blocking, the `IO` pool can become a bottleneck during intensive export or import.

To increase the number of `threads` in the IO pool, change the parameter in the actor system configuration:

```
actor_system_config:
  executor:
  - name: IO
    threads: 3
    time_per_mailbox_micro_secs: 100
    type: IO
```

Tip

Recommendations for choosing the number of IO pool threads when using NFS export/import:

- Start with `2` threads and monitor the load.
- Keep in mind that the IO pool handles not only NFS operations but also other blocking tasks (e.g., writing logs).
- Monitor the pool load via the YDB UI.

Logging

The progress of export and import operations is reflected in the YDB server logs. The main logging components are:

- `EXPORT` — logging of the export process on SchemeShard: creating directories, copying tables, starting backup tasks, loading the schema.
- `IMPORT` — logging of the import process on SchemeShard: reading metadata, creating tables, restoring data.
- `FS_WRAPPER` — logging of file operations on each node. This component records I/O errors (file unavailability, insufficient space, locking errors), which helps identify issues with NFS mounting on specific nodes.

When diagnosing issues, it is recommended to:

- Check the operation status via `ydb operation get`.
- Search the server logs for entries with components `EXPORT` or `IMPORT` and the operation ID.
- For file write or read errors, search the logs for entries with component `FS_WRAPPER` — they contain the file path and error description, which helps determine on which host and with which file the problem occurred.
- Verify that the NFS directory is accessible and has enough free space on **all** cluster nodes.

Limitations

- Export and import via NFS support the same object types as export to S3. A detailed list of supported objects is provided in the export command documentation.
- Import always creates objects from scratch — you cannot import into existing tables.
- The `--list` parameter for listing export objects is available only for import from S3 in the current version.
- The operation is not supported on the Windows platform.

Recipes for streaming queries

This section contains recipes for working with streaming queries.

Contents:

- Quick start: reading and writing to topics
- Debug reads from a topic

Quick start: reading and writing to topics

In this guide, you will create your first streaming query.

The query will:

- read events from the input topic
- filter only errors
- count the number of errors per server over 10 minutes
- write the result to the output topic.

Events arrive in JSON format with fields: time, logging level, and server name.

You will perform the following steps:

- Create topics;
- Create the streaming query;
- Check query state;
- Produce sample input;
- Read the output topic;
- Delete the streaming query.

Prerequisites

To run the examples, you will need:

- A running YDB database — see quick start;
- The `enable_streaming_queries` feature flag enabled.

Docker

```
docker run -d --rm --name ydb-local -h localhost \
  --platform linux/amd64 \
  -p 2135:2135 -p 2136:2136 -p 8765:8765 -p 9092:9092 \
  -v $(pwd)/ydb_certs:/ydb_certs \
  -e GRPC_TLS_PORT=2135 -e GRPC_PORT=2136 -e MON_PORT=8765 \
  -e YDB_FEATURE_FLAGS=enable_streaming_queries \
  ydbplatform/local-ydb:25.4
```

local_ydb

```
./local_ydb deploy \
  --ydb-working-dir=/absolute/path/to/working/directory \
  --ydb-binary-path=/path/to/kikimr/driver \
  --enable-feature-flag=enable_streaming_queries
```

> **Note**
>
> The examples use the `quickstart` profile. To learn more, see Creating a profile to connect to a test database.

Step 1. Creating topics

Create the input and output topics:

```
CREATE TOPIC input_topic;
CREATE TOPIC output_topic;
```

Verify that the topics are created:

```
./ydb --profile quickstart scheme ls
```

Step 2. Create the streaming query

Create a streaming query with CREATE STREAMING QUERY:

```
CREATE STREAMING QUERY query_example AS
DO BEGIN

$number_errors = SELECT
    Host,
    COUNT(*) AS ErrorCount,
    CAST(HOP_START() AS String) AS Ts  -- Start time of the window corresponding to the aggregation result
FROM
    input_topic
WITH (
    FORMAT = json_each_row,
    SCHEMA = (
        Time String NOT NULL,
        Level String NOT NULL,
        Host String NOT NULL
    )
)
WHERE
    Level = "error"
GROUP BY
    HOP(CAST(Time AS Timestamp), "PT600S", "PT600S", "PT0S"),  -- Number of errors on non-overlapping windows
of 10 minutes length
    Host;

INSERT INTO
    output_topic
SELECT
    ToBytes(Unwrap(Yson::SerializeJson(Yson::From(TableRow()))))  -- Serialization of all columns into JSON
FROM
    $number_errors;

END DO
```

More details:

- `GROUP BY HOP` aggregation and `HOP_START` — GROUP BY ... HOP.
- Writing to a topic — Formats for writing data.
- JSON serialization: TableRow, Yson::From, Yson::SerializeJson, Unwrap, ToBytes.

Step 3. Check query state

Check query state in the streaming_queries system table:

```
SELECT
    Path,
    Status,
    Issues,
    Run
FROM
    `.sys/streaming_queries`
```

Make sure that the `Status` field has the value `RUNNING`. Otherwise, check the `Issues` field.

If the query is in `SUSPENDED` status or the `Issues` field contains errors, see the error diagnostics section.

Step 4. Produce sample input

Write test messages to the topic using the YDB CLI:

```
echo '{"Time": "2025-01-01T00:00:00.000000Z", "Level": "error", "Host": "host-1"}' | ./ydb --profile quicksta
rt topic write input_topic
echo '{"Time": "2025-01-01T00:04:00.000000Z", "Level": "error", "Host": "host-2"}' | ./ydb --profile quicksta
rt topic write input_topic
echo '{"Time": "2025-01-01T00:08:00.000000Z", "Level": "error", "Host": "host-1"}' | ./ydb --profile quicksta
rt topic write input_topic
echo '{"Time": "2025-01-01T00:12:00.000000Z", "Level": "error", "Host": "host-2"}' | ./ydb --profile quicksta
rt topic write input_topic
echo '{"Time": "2025-01-01T00:12:00.000000Z", "Level": "error", "Host": "host-1"}' | ./ydb --profile quicksta
rt topic write input_topic
```

Results appear in the output topic after the 10-minute aggregation window closes.

Step 5. Read the output topic

Read data from the output topic:

```
./ydb --profile quickstart topic read output_topic --partition-ids 0 --start-offset 0 --limit 10 --format new
line-delimited
```

Expected result:

```
{"ErrorCount":1,"Host":"host-2","Ts":"2025-01-01T00:00:00Z"}
{"ErrorCount":2,"Host":"host-1","Ts":"2025-01-01T00:00:00Z"}
```

Step 6. Delete the query

Delete the query with DROP STREAMING QUERY:

```
DROP STREAMING QUERY query_example;
```

What's next

- Explore the data formats supported in streaming queries.
- Learn how to enrich data with a reference from a local table or from S3.
- Learn how to write results to tables.

See also

- Streaming queries
- Data formats for reading/writing from topics.

Debug reads from a topic

When developing streaming queries, it is often useful to inspect what arrives in a topic without creating a full streaming query. Run a regular `SELECT` with `STREAMING = "TRUE"`.

> **Warning**
>
> For debugging and inspection only. For production, create streaming queries with CREATE STREAMING QUERY.

> **Note**
>
> In the examples, `ydb_source` is a pre-created external data source, and `topic_name` / `input_topic` are topics available through it.

Raw reads

Simplest option — read messages in `raw` format without parsing:

```
SELECT
    Data
FROM
    ydb_source.topic_name
WITH (
    FORMAT = raw,
    SCHEMA = (
        Data String
    ),
    STREAMING = "TRUE"
)
LIMIT 1
```

`LIMIT` is required; without it the query never completes because it waits for new messages indefinitely.

JSON parsing

If the topic stores JSON, parse fields directly:

```
SELECT
    *
FROM
    ydb_source.topic_name
WITH (
    FORMAT = json_each_row,
    SCHEMA = (
        Time String NOT NULL,
        Level String NOT NULL,
        Host String NOT NULL
    ),
    STREAMING = "TRUE"
)
LIMIT 5
```

- Data formats for reading/writing from topics — supported data formats
- Streaming read from a topic — `STREAMING = "TRUE"` in the YQL reference

Troubleshooting

This section of the YDB documentation provides guidance on troubleshooting issues related to YDB databases and the applications that interact with them.

- Troubleshooting performance issues

Troubleshooting performance issues

Addressing database performance issues often requires a holistic approach, which includes optimizing queries, properly configuring hardware resources, and ensuring that both the database and the application are well-designed. Regular monitoring and maintenance are essential for proactively identifying and resolving these issues.

Tools to troubleshoot performance issues

Troubleshooting performance issues in YDB involves the following tools:

- YDB metrics

  Diagnostic steps for most performance issues involve analyzing Grafana dashboards that use YDB metrics collected by Prometheus For information about how to set up Grafana and Prometheus, see Setting Up YDB Cluster Monitoring.
- YDB logs
- Tracing
- YDB CLI
- YDB UI
- Query execution optimization;
- Parameterized queries and recompilation;
- Third-party observability tools

Classification of YDB performance issues

Database performance issues can be classified into several categories based on their nature. This documentation section provides a high-level overview of these categories, starting with the lowest layers of the system and going all the way to the client. Below is a separate section for the actual performance troubleshooting instructions.

Hardware infrastructure issues

- **Network issues**. Network congestion in data centers and especially between data centers can significantly affect YDB performance.
- **Data center outages**: Disruptions in data center operations that can cause service or data unavailability. To address this concern, YDB cluster can be configured to span three data centers or availability zones, but the performance aspect needs to be taken into account too.
- **Data center maintenance and drills**. Planned maintenance or drills, exercises conducted to prepare personnel for potential emergencies or outages, can also affect query performance. Depending on the maintenance scope or drill scenario, some YDB servers might become unavailable, which leads to the same impact as an outage.
- **Server hardware issues**. Malfunctioning CPU, memory modules, and network cards, until replaced, significantly impact database performance or lead to the unavailability of the affected server.

Insufficient resource issues

These issues refer to situations when the workload demands more physical resources — such as CPU, memory, disk space, and network bandwidth — than allocated to a database. In some cases, suboptimal allocation of resources, for example misconfigured control groups (cgroups) or actor system pools, may also result in insufficient resources for YDB and increase query latencies even though physical hardware resources are still available on the database server.

- **CPU bottlenecks**. High CPU usage can result in slow query processing and increased response times. When CPU resources are limited, the database may struggle to handle complex queries or large transaction loads.
- **Insufficient disk space**. A lack of available disk space can prevent the database from storing new data, resulting in the database becoming read-only. This might also cause slowdowns as the system tries to reclaim disk space by compacting existing data more aggressively.
- **Insufficient memory (RAM)**. Queries require memory to temporarily store various intermediate data during execution. A lack of available memory can negatively impact database performance in multiple ways.
- **Insufficient disk I/O bandwidth**. A high rate of read/write operations can overwhelm the disk subsystem, causing increased data access latencies. When the distributed storage cannot read or write data quickly enough, queries requiring disk access will take longer to execute.

Operating system issues

- **System clock drift**. If the system clocks on the YDB servers start to drift apart, it will lead to increased distributed transaction latencies. In severe cases, YDB might even refuse to process distributed transactions and return errors.
- Other processes running on the same servers or virtual machines as YDB, such as antiviruses, observability agents, etc.
- Kernel misconfiguration.

YDB-related issues

- **Updating YDB versions**. There are two main related aspects: restarting all nodes within a relatively short timeframe, and the behavioral differences between versions.
- Actor system pools misconfiguration.

Schema design issues

- **Overloaded shards**. Data shards serving row-oriented tables may become overloaded for several reasons. Such overload leads to increased latencies for the transactions processed by the affected data shards.
- **Excessive tablet splits and merges**. YDB supports automatic splitting and merging of data shards, which allows it to seamlessly adapt to changes in workloads. However, these operations are not free and might have a short-term negative impact on query latencies.

Client application-related issues

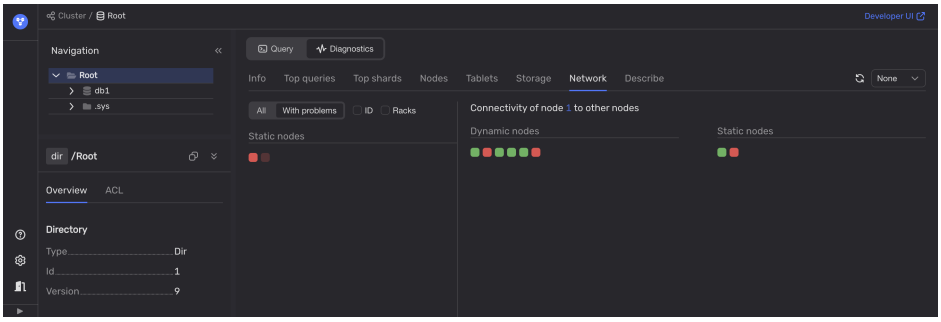
- **Query design issues**. Inefficiently designed database queries may execute slower than expected.
- **SDK usage issues**. Issues related to improper or suboptimal use of the SDK.

Instructions

To troubleshoot YDB performance issues, treat each potential cause as a hypothesis. Systematically review the list of hypotheses and verify whether they apply to your situation. The documentation for each cause provides a description, guidance on how to check diagnostics, and recommendations on what to do if the hypothesis is confirmed.

If any known changes occurred in the system around the time the performance issues first appeared, investigate those first. Otherwise, follow this recommended order for evaluating potential root causes. This order is loosely based on the descending frequency of their occurrence on large production YDB clusters.

1. Overloaded shards and errors
2. Excessive tablet splits and merges
3. Frequent tablet moves between nodes
4. Insufficient hardware resources:
    - Disk I/O bandwidth
    - Disk space
    - Insufficient CPU
    - Insufficient memory
5. Hardware issues and data center outages
6. Network issues
7. Rolling restart
8. System clock drift
9. Transaction lock invalidation
10. Data center maintenance and drills



Network issues

Network performance issues, such as limited bandwidth, packet loss, and connection instability, can severely impact database performance by slowing query response times and leading to retriable errors like timeouts.

Diagnostics

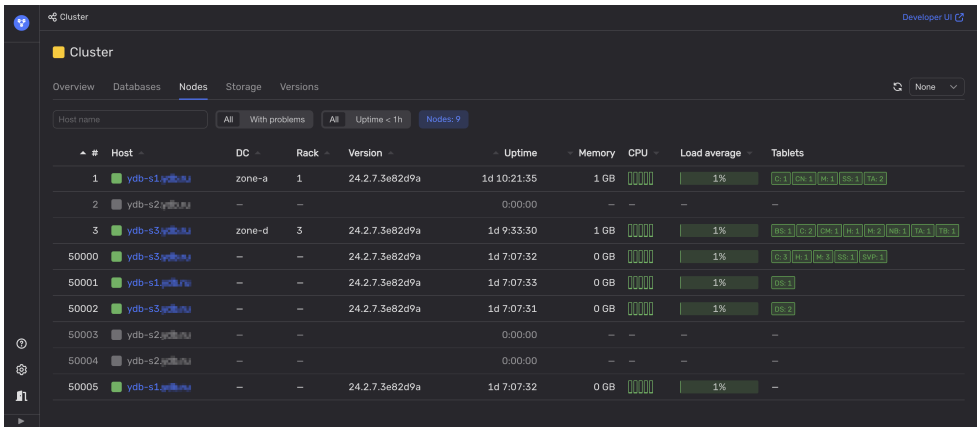
To diagnose network issues, use the healthcheck in the YDB UI:

1. Open the YDB UI:
   1.1. Navigate to the **Databases** tab and click on the desired database.
   1.2. In the **Navigation** tab, confirm the required database is selected.
   1.3. Switch to the **Diagnostics** tab.
   1.4. Under the **Network** tab, apply the **With problems** filter.

2. Use available third-party tools to monitor network performance metrics such as latency, jitter, packet loss, throughput, and others.

Recommendations

Contact the responsible party for the network infrastructure the YDB cluster uses. If you are part of a larger organization, this could be an in-house network operations team. Otherwise, contact the cloud service or hosting provider's support service.



Data center outages

Data center outages are disruptions in data center operations that could cause service or data unavailability, but YDB has means to avoid it. Various factors, such as power failures, natural disasters, or cyberattacks, may cause these outages. A common fault-tolerant setup for YDB spans three data centers or availability zones (AZs). In this case, YDB can maintain uninterrupted operation even if one data center and a server rack in another are lost. However, it will initiate the relocation of tablets from the offline AZ to the remaining online nodes, temporarily leading to higher query latencies.

Diagnostics

To determine if one of the data centers of the YDB cluster is not available, follow these steps:

1. Open YDB UI.
2. On the **Nodes** tab, analyze the health indicators in the **Host** and **DC** columns.

   If all of the nodes in one of the data centers (DC) are not available, this data center is most likely offline.

   If not, review the **Rack** column to check if all YDB nodes are unavailable in one or more server racks. This could indicate that these racks are offline, which could be treated as a partial data center outage.

Recommendations

Contact the responsible party for the affected data center to resolve the underlying issue. If you are part of a larger organization, this could be an in-house team managing low-level infrastructure. Otherwise, contact the cloud service or hosting provider's support service. Meanwhile, check the data center's status page if it has one.

Additionally, consider potential data center outages in the capacity planning process. YDB nodes in each data center should have sufficient spare hardware resources to take over the full workload typically handled by any data center experiencing an outage.

Data center maintenance and drills

Planned maintenance or drills, exercises conducted to prepare personnel for potential emergencies or outages, can also affect query performance. Depending on the maintenance scope or drill scenario, some YDB nodes might become unavailable, which leads to the same impact as an outage.

Diagnostics

Check the planned maintenance and drills schedules to see if their timelines match with observed performance issues, otherwise, check the datacenter outage recommendations.

Recommendations

Contact the person responsible for the current maintenance or drill to discuss whether the performance impact is severe enough for it to be finished/canceled early, if possible.

Hardware issues

Malfunctioning storage drives and network cards, until replaced, significantly impact database performance up to total unavailability of the affected server. CPU issues might lead to server failure and higher load on the remaining YDB nodes.

Diagnostics

Use the hardware monitoring tools that your operating system and data center provide to diagnose hardware issues.

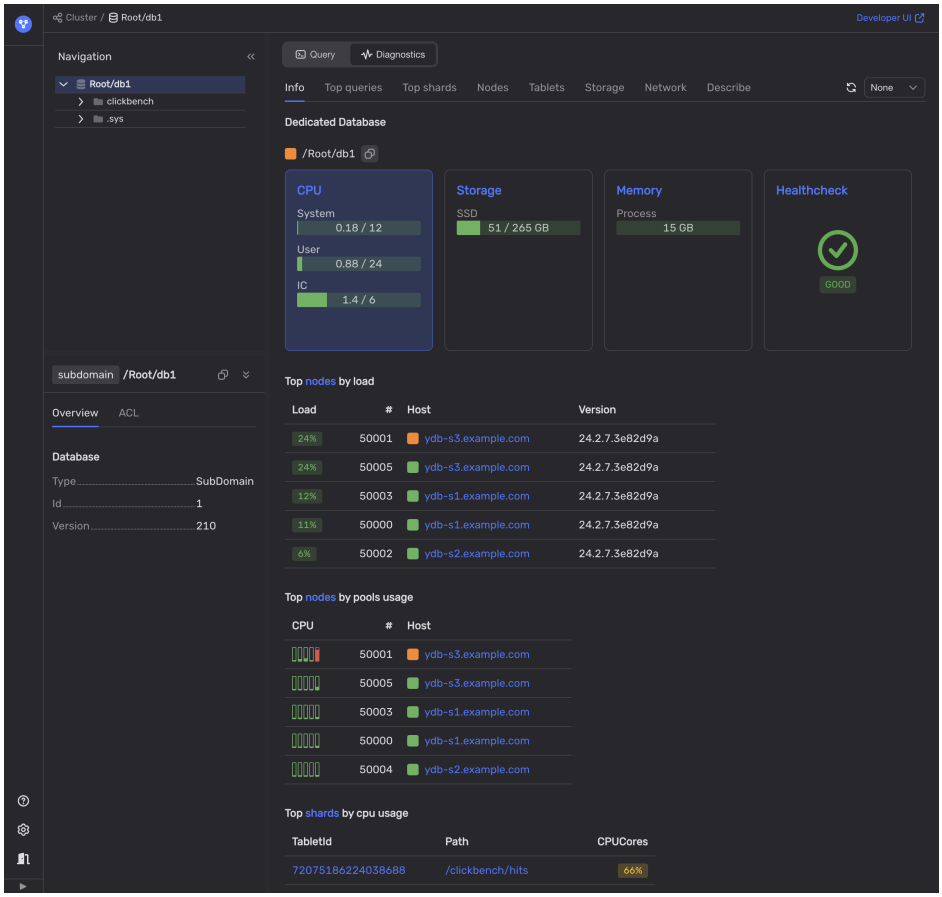
You can also use the **Healthcheck** in YDB UI to diagnose some hardware issues:

- **Storage issues**
  1. On the **Storage** tab, select the **Degraded** filter to list storage groups or nodes that contain degraded or failed storage.
  2. Check for any degradation in the storage system performance on the **Distributed Storage Overview** and **PDisk Device single disk** dashboards in Grafana.
- **Network issues**

  Refer to Network issues.

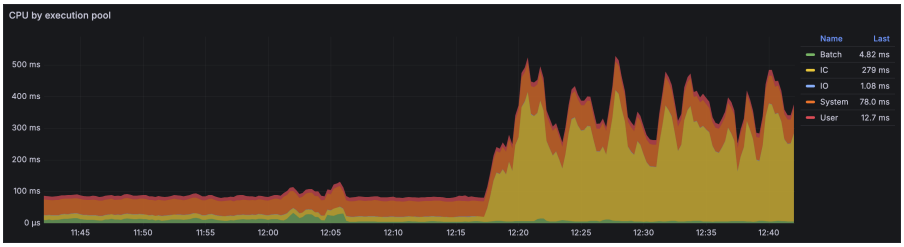
Recommendations

Contact the responsible party for the affected hardware to resolve the underlying issue. If you are part of a larger organization, this could be an in-house team managing low-level infrastructure. Otherwise, contact the cloud service or hosting provider's support service.



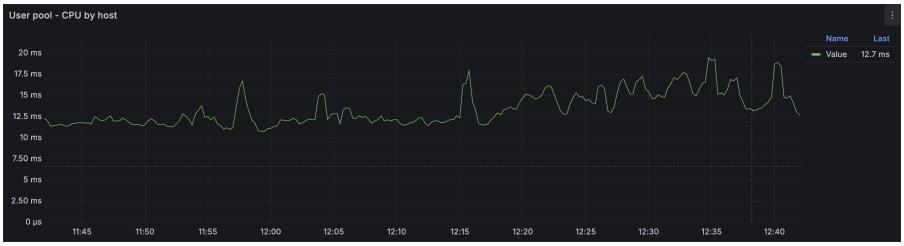
CPU bottleneck

High CPU usage can lead to slow query processing and increased response times. When CPU resources are constrained, the database may have difficulty handling complex queries or large transaction volumes.



YDB nodes primarily consume CPU resources for running actors. On each node, actors are executed using multiple actor system pools. The resource consumption of each pool is measured separately which allows to identify what kind of activity changed its behavior.

Diagnostics

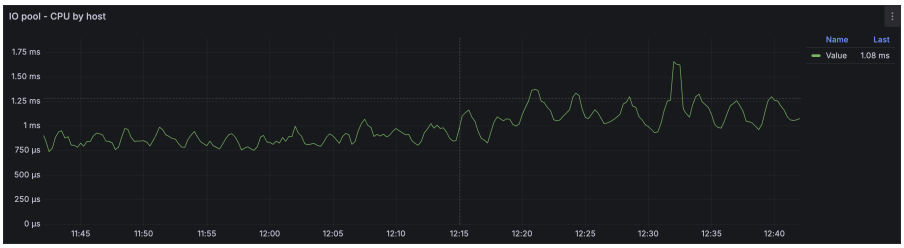


1. Use **Diagnostics** in the YDB UI to analyze CPU utilization in all pools:
   1.1. In the YDB UI, go to the **Databases** tab and click on the database.
   1.2. On the **Navigation** tab, ensure the required database is selected.
   1.3. Open the **Diagnostics** tab.
   1.4. On the **Info** tab, click the **CPU** button and see if any pools show high CPU usage.

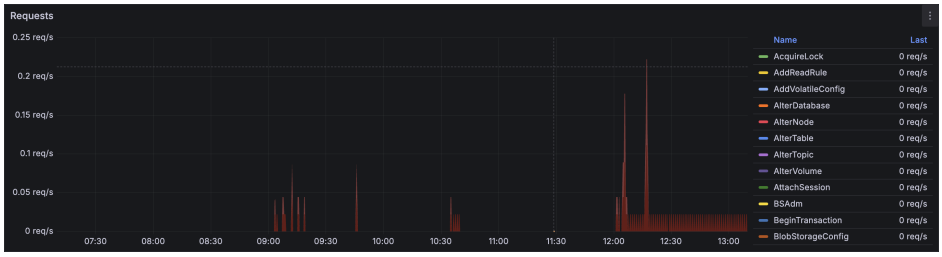
2. Use Grafana charts to analyze CPU utilization in all pools:
   2.1. Open the **CPU** dashboard in Grafana.
   2.2. See if the following charts show any spikes:
   - **CPU by execution pool** chart

   - **User pool - CPU by host** chart

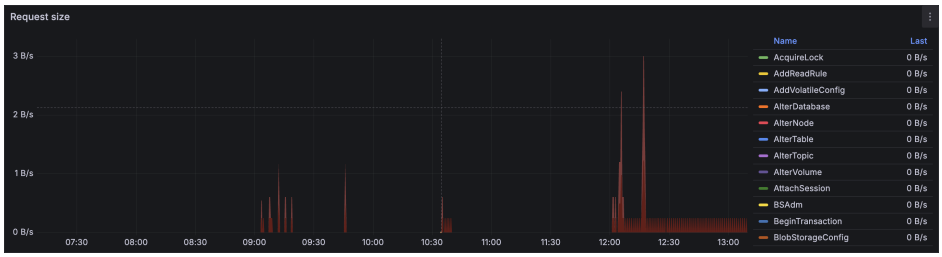
   - **System pool - CPU by host** chart



- **Batch pool - CPU by host** chart



- **IC pool - CPU by host** chart



- **IO pool - CPU by host** chart

3. If the spike is in the user pool, analyze changes in the user load that might have caused the CPU bottleneck. See the following charts on the **DB overview** dashboard in Grafana:
   - **Requests** chart

   - **Request size** chart

   - **Response size** chart

   Also, see all of the charts in the **Operations** section of the **DataShard** dashboard.
4. If the spike is in the batch pool, check if there are any backups running.

Recommendation

Add additional database nodes to the cluster or allocate more CPU cores to the existing nodes. If that's not possible, consider distributing CPU cores between pools differently.

Insufficient memory (RAM)

If swap (paging of anonymous memory) is disabled on the server running YDB, insufficient memory activates another kernel feature called the OOM killer, which terminates the most memory-intensive processes (often the database itself). This feature also interacts with cgroups if multiple cgroups are configured.

If swap is enabled, insufficient memory may cause the database to rely heavily on disk I/O, which is significantly slower than accessing data directly from memory.

> **Warning**
>
> If YDB nodes are running on servers with swap enabled, disable it. YDB is a distributed system, so if a node restarts due to lack of memory, the client will simply connect to another node and continue accessing data as if nothing happened. Swap would allow the query to continue on the same node but with degraded performance from increased disk I/O, which is generally less desirable.

Even though the reasons and mechanics of performance degradation due to insufficient memory might differ, the symptoms of increased latencies during query execution and data retrieval are similar in all cases.

Additionally, which components within the YDB process consume memory may also be significant.

Diagnostics

1. Determine whether any YDB nodes recently restarted for unknown reasons. Exclude cases of YDB version upgrades and other planned maintenance. This could reveal nodes terminated by OOM killer and restarted by `systemd`.
   1.1. Open YDB UI.
   1.2. On the **Nodes** tab, look for nodes that have low uptime.
   1.3. Chose a recently restarted node and log in to the server hosting it. Run the `dmesg` command to check if the kernel has recently activated the OOM killer mechanism.

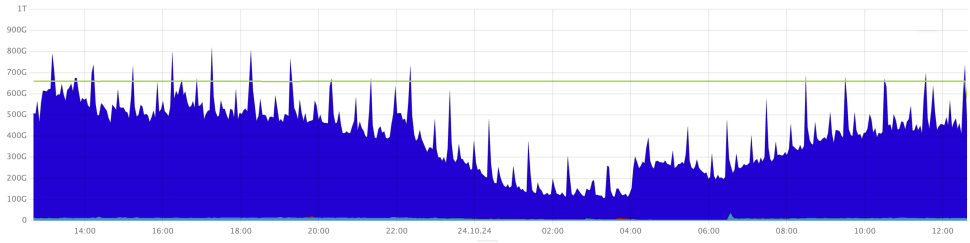
   Look for the lines like this:

   ```
   [ 2203.393223] oom-kill:constraint=CONSTRAINT_NONE,nodemask=(null),cpuset=user.slice,mems_allowed=0,
   global_oom,task_memcg=/user.slice/user-1000.slice/session-1.scope,task=ydb,pid=1332,uid=1000
   [ 2203.393263] Out of memory: Killed process 1332 (ydb) total-vm:14219904kB, anon-rss:1771156kB, fil
   e-rss:0kB, shmem-rss:0kB, UID:1000 pgtables:4736kB oom_score_adj:0
   ```

   Additionally, review the `ydbd` logs for relevant details.
2. Determine whether memory usage reached 100% of capacity.
   2.1. Open the **DB overview** dashboard in Grafana.
   2.2. Analyze the charts in the **Memory** section.
3. Determine whether the user load on YDB has increased. Analyze the following charts on the **DB overview** dashboard in Grafana:
   - **Requests** chart
   - **Request size** chart
   - **Response size** chart
4. Determine whether new releases or data access changes occurred in your applications working with YDB.

Recommendation

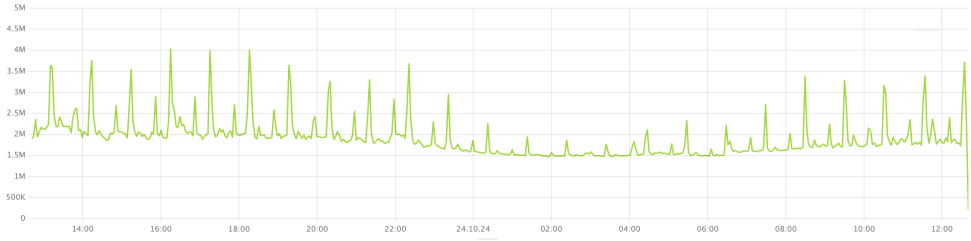
Consider the following solutions for addressing insufficient memory:



- If the load on YDB has increased due to new usage patterns or increased query rate, try optimizing the application to reduce the load on YDB or add more YDB nodes.
- If the load on YDB has not changed but nodes are still restarting, consider adding more YDB nodes or raising the hard memory limit for the nodes. For more information about memory management in YDB, see memory_controller_config.

I/O bandwidth

A high rate of read and write operations can overwhelm the disk subsystem, leading to increased data access latencies. When the system cannot read or write data quickly enough, queries that rely on disk access will experience delays.



Diagnostics

1. Open the **Distributed Storage Overview** dashboard in Grafana.
2. On the **DiskTimeAvailable and total Cost relation** chart, see if the **Total Cost** spikes cross the **DiskTimeAvailable** level.

This chart shows the estimated total bandwidth capacity of the storage system in conventional units (green) and the total usage cost in conventional units (blue). When the total usage cost exceeds the total bandwidth capacity, the YDB storage system becomes overloaded, leading to increased latencies.

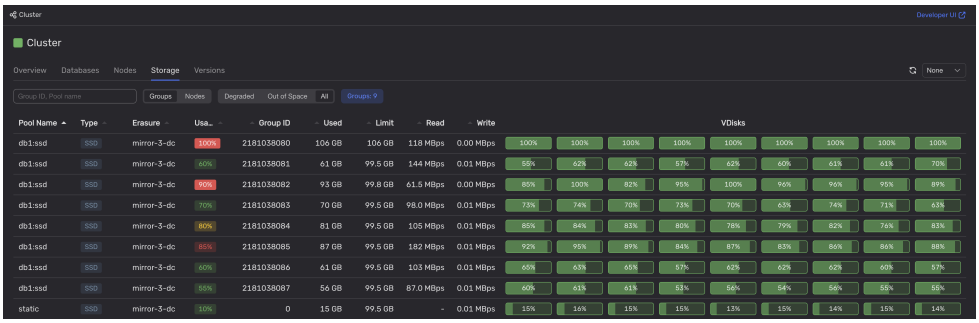
3. On the **Total burst duration** chart, check for any load spikes on the storage system. This chart displays microbursts of load on the storage system, measured in microseconds.

> **Note**
>
> This chart might show microbursts of the load that are not detected by the average usage cost in the **Cost and DiskTimeAvailable relation** chart.

Recommendations

Add more storage groups to the database.

In cases of high microburst rates, balancing the load across storage groups might help.



Disk space

A lack of available disk space can prevent the database from storing new data, resulting in the database becoming read-only. This can also cause slowdowns as the system tries to reclaim disk space by compacting existing data more aggressively.

Diagnostics

1. See if the **DB overview > Storage** charts in Grafana show any spikes.
2. In YDB UI, on the **Storage** tab, analyze the list of available storage groups and nodes and their disk usage.

> **Tip**
>
> Use the **Out of Space** filter to list only the storage groups with full disks.

> **Note**
>
> It is also recommended to use the Healthcheck API to get this information.

Recommendations

Add more storage groups to the database.

If the cluster doesn't have spare storage groups, configure them first. Add additional storage nodes, if necessary.

System clock drift

Synchronized clocks are critical for distributed databases. If system clocks on the YDB servers drift excessively, distributed transactions will experience increased latencies.

> **Alert**
>
> It is important to keep system clocks on the YDB servers in sync, to avoid high latencies.

Symptoms and thresholds

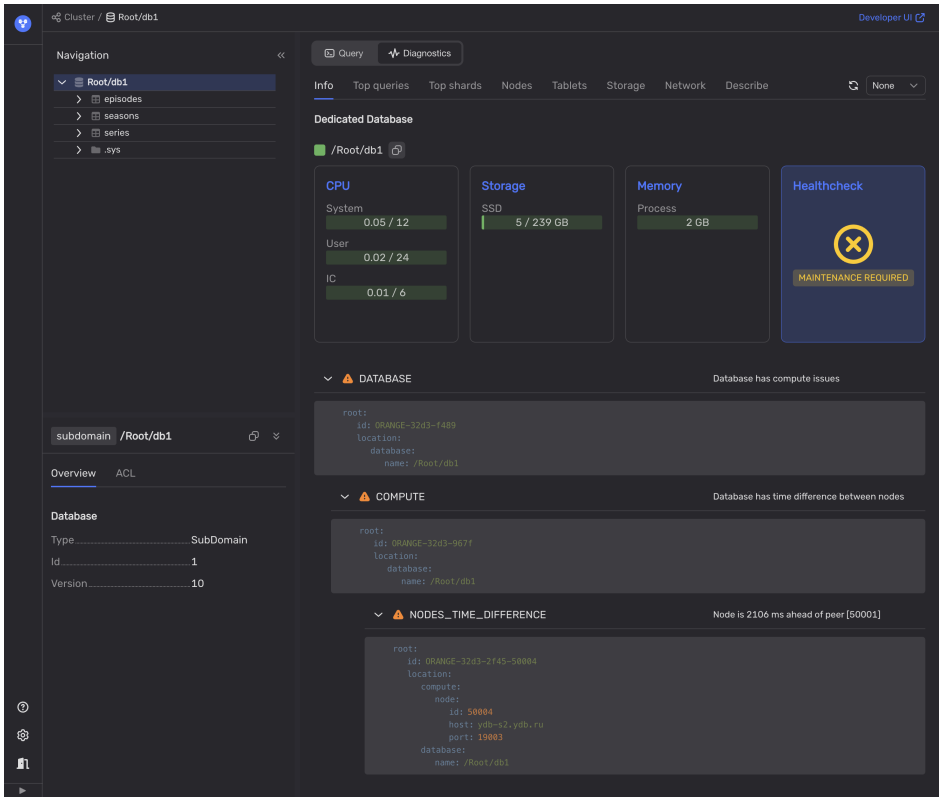
Typical symptoms of clock skew across nodes:

- **Slower distributed transactions** — end-to-end latency can increase roughly by the amount of clock skew (a node with a "faster" clock waits for coordination with nodes that lag behind).
- **Timeouts and deadline issues** — skew can cause spurious client/server timeouts and deadline failures.
- **Authentication issues** — large skew can break token validity windows and related checks.

When monitoring clock skew between nodes, use these thresholds (typical levels for cluster observability):

- **Less than 1 millisecond** — normal level for routine cluster operation.
- **1—5 milliseconds** — a range where it already makes sense to look for the cause of desynchronization and increase observability.
- **More than 5 milliseconds** — critical level: urgent diagnosis and time alignment are required.
- **25 milliseconds and above** — growing performance degradation; users see widespread latency issues and timeouts on distributed transactions.
- **30 seconds** — distributed transactions stop working (see below).

If the system clocks of the nodes running the coordinator tablets differ noticeably from one another, transaction latencies increase by the time difference between the fastest and slowest system clocks. This occurs because a transaction planned on a node with a faster system clock can only be executed once the node with the slowest clocks reaches the same time.



Furthermore, if the system clock drift exceeds 30 seconds, YDB will refuse to process distributed transactions. Before coordinators start planning a transaction, affected data shards determine an acceptable range of timestamps for the transaction. The start of this range is the current system time of the mediator tablet, and the end is defined by the 30-second planning timeout. If the coordinator's system clock falls outside this time range, it cannot plan a distributed transaction, resulting in errors for such queries.

Diagnostics

To diagnose system clock drift on YDB servers, use the following methods:

1. Use **Healthcheck** in the YDB UI:
   1.1. In the YDB UI, go to the **Databases** tab and click on the database.
   1.2. On the **Navigation** tab, ensure the required database is selected.
   1.3. Open the **Diagnostics** tab.
   1.4. On the **Info** tab, click the **Healthcheck** button.

   If the **Healthcheck** button displays a `MAINTENANCE REQUIRED` status, the YDB cluster might be experiencing issues, such as system clock drift. Any identified issues will be listed in the **DATABASE** section below the **Healthcheck** button.
   1.5. To see the diagnosed problems, expand the **DATABASE** section.

System clock drift problems are listed under `NODES_TIME_DIFFERENCE`.

> **Note**
>
> For more information, see Health Check API

2. Open the Interconnect overview page in the YDB UI. Interconnect metrics (including indicators related to clock skew across nodes) help assess the scope of the issue alongside the overall picture of connectivity latency and errors.

> **Note**
>
> An increase in system clock skew according to interconnect monitoring (as shown in the YDB UI and collected via cluster metrics) may be caused by actual clock drift, exhaustion of resources in the interconnect CPU pool, or network equipment overload.

3. Use such tools as `pssh` or `ansible` to run the command (for example, `date +%s%N`) on all YDB nodes to display the system clock value.

> **Warning**
>
> Network delays between the host that runs `pssh` or `ansible` and YDB hosts will influence the results.

If you use time synchronization utilities, you can also request their status instead of requesting the current timestamps. For example:

```
chronyc sources -v
```

It is also useful to review cluster monitoring metrics (if you collect them): transaction latency and gRPC success rates may degrade together with interconnect indicators when skew is present (in particular, the `interconnect.ClockSkewMicrosec` metric).

Recommendations

1. Manually synchronize the system clocks of servers running YDB nodes. For instance, use `pssh` or `ansible` to run the clock sync command across all nodes.
2. Ensure that system clocks on all YDB servers are regularly synchronized using `ntpd`, `chrony`, or a similar tool. Use the same logical time source for every server in the cluster (the same set of NTP servers or the same NTP hierarchy) and configure multiple independent upstream NTP sources.

> **Warning**
>
> Using the **systemd-timesyncd** service is not recommended, because this type of NTP client does not provide sufficient accuracy for system time synchronization. Use other tools instead, such as `chrony` or `ntpd`.

NTP configuration examples

Below are example settings for `chrony`. Replace the server list with values appropriate for your environment and security policy.

chrony (`/etc/chrony/chrony.conf`):

```
server ntp1.example.net iburst
server ntp2.example.net iburst
server ntp3.example.net iburst
server ntp4.example.net iburst
maxslewrate 10000
local stratum 10
```

Monitoring and alerting

Configure alerts on clock skew between nodes and related symptoms (including YDB UI data and external monitoring). See Symptoms and thresholds for threshold guidance.

Emergency recovery

If skew becomes critical, you may need forced synchronization (perform this deliberately and according to your cluster's agreed procedure):

```
# Example for chrony: stop the service and perform a one-shot sync
sudo systemctl stop chrony
sudo chronyd -q 'server ntp1.example.net iburst'
sudo systemctl start chrony
```

Suggested sequence on a cluster:

1. Verify NTP servers are correct and reachable.
2. Align time across nodes (without divergent per-node configuration).
3. Confirm convergence via Healthcheck and monitoring.
4. Identify the root cause of the synchronization failure (network, DNS, blocked NTP egress, etc.).

Prevention

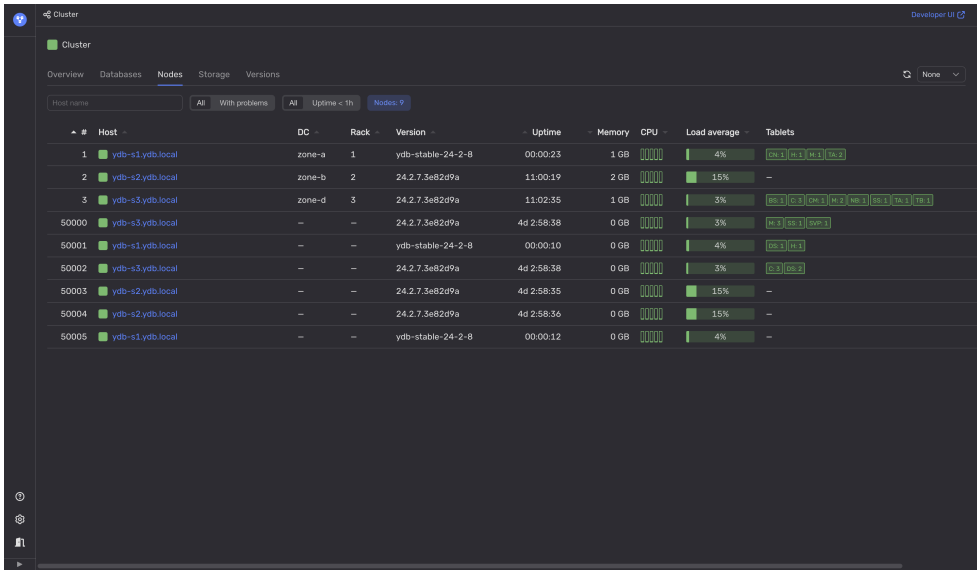
- Periodically review metrics and Healthcheck reports for growing skew.
- Validate NTP fault tolerance (multiple NTP servers; UDP/123 reachability if applicable).
- Keep the configuration of the NTP client you use consistent across all cluster nodes.

Rolling restart

YDB clusters can be updated without downtime, which is possible because YDB normally has redundant components and supports rolling restart procedure. To ensure continuous data availability, YDB includes Cluster Management System (CMS) that tracks all outages and nodes taken offline for maintenance, such as restarts. CMS halts new maintenance requests if they might risk data availability.

However, even if data is always available, the restart of all nodes in a relatively short period of time might have a noticeable impact on overall performance. Each tablet running on a restarted node is relaunched on a different node. Moving a tablet between nodes takes time and may affect latencies of queries involving it. See recommendations for rolling restart.

Furthermore, a new YDB version may handle queries differently. While performance generally improves with each update, certain corner cases may occasionally end up with degraded performance. See recommendations for new version performance.



Diagnostics

> **Warning**
>
> Diagnostics of YDB rolling restarts and updates relies only on secondary symptoms. To be absolutely sure, contact your database administrator.

To check if the YDB cluster is currently being updated:

1. Open YDB UI.
2. On the **Nodes** tab, see if YDB versions of the nodes differ.

   Also, see if the nodes with the higher YDB version have the lower uptime value.

> **Alert**
>
> Low uptime value of a YDB node might also indicate other problems. For example, see Insufficient memory (RAM).

Recommendations

For rolling restart

If the ongoing YDB cluster rolling restart significantly impacts applications to the point where they can no longer meet their latency requirements, consider slowing down the restart process:

1. If nodes are restarted in batches, reduce the batch size, up to one node at a time.
2. Space out in time the restarts for each data center and/or server rack.
3. Inject artificial pauses between restarts.

For new version performance

The goal is to detect any negative performance impacts from the new YDB version on specific queries in your particular workload as early as possible:

1. Review the YDB server changelog for any performance-related notes relevant to your workload.
2. Use a dedicated pre-production and/or testing YDB cluster to run a workload that closely mirrors your production workload. Always deploy the new YDB version to these clusters first. Monitor both client-side latencies and server-side metrics to identify any potential performance issues.
3. Implement canary deployment by updating only one node initially to observe any changes in its behavior. If everything appears stable, gradually expand the update to more nodes, such as an entire server rack or data center, and repeat checks for anomalies. If any issues arise, immediately roll back to the previous version and attempt to reproduce the issue in a non-production environment.

Report any identified performance issues on YDB's GitHub. Provide context and all the details that could help reproduce it.

Frequent tablet moves between nodes

YDB automatically balances the load by moving tablets from overloaded nodes to other nodes. This process is managed by Hive. When Hive moves tablets, queries affecting those tablets might experience increased latencies while they wait for the tablet to get initialized on the new node.

YDB considers usage of the following hardware resources for balancing nodes:

- CPU
- Memory
- Network
- Counter[14]

Autobalancing occurs in the following cases:

- **Imbalanced Hardware Resource Usage**

  YDB uses the Scatter metric to evaluate the balance of hardware resource usage. For more details on the Scatter metric's calculation logic and balancing triggers, see the Resource Usage Imbalance section.
- **Overloaded nodes (CPU and memory usage)**

  Hive initiates balancing in case of a significant load asymmetry (for example, > 90% on one node and < 70% on another). Learn more here: Node Overload.
- **Uneven distribution of database objects**

  For tablets with no explicit resource consumption, Hive uses a fake **Counter** resource to ensure their even distribution. Balancing is triggered if this distribution becomes skewed. Learn more: Even Distribution for a Specific Object.

Diagnostics

1. See if the **Tablets moved by Hive** chart in the **DB status** Grafana dashboard shows any spikes.

```
This chart displays the time-series data for the number of tablets moved per second.
```

2. See the Hive balancer stats.
   2.1. Open YDB UI.
   2.2. Click **Developer UI** in the upper right corner of the YDB UI.
   2.3. In the **Developer UI**, navigate to **Tablets > Hive > App**.

   See the balancer stats in the upper right corner.

Balancer	Runs	Moves	Last run	Last moves	Progress
Counter	0	0			
CPU	14	14	2024-10-18T12:05:44.342466Z	1	
Memory	0	0			
Network	0	0			
Emergency	0	0			
Spread	0	0			
Scatter	0	0			
Manual	0	0			
Storage	0	0			

   2.4. Additionally, to see the recently moved tablets, click the **Balancer** button.

   The **Balancer** window will appear. The list of recently moved tablets is displayed in the **Latest tablet moves** section.

Recommendations

Adjust Hive balancer settings:

1. Open YDB UI.
2. Click **Developer UI** in the upper right corner of the YDB UI.
3. In the **Developer UI**, navigate to **Tablets > Hive > App**.

4. Click **Settings**.
5. To reduce the likelihood of overly frequent balancing, increase the following Hive balancer thresholds:

Parameter	Description	Default value
MinCounterScatterToBalance	The threshold for the counter scatter value. When this value is reached, Hive starts balancing the load.	0.02
MinCPUScatterToBalance	The threshold for the CPU scatter value. When this value is reached, Hive starts balancing the load.	0.5
MinMemoryScatterToBalance	The threshold for the memory scatter value. When this value is reached, Hive starts balancing the load.	0.5
MinNetworkScatterToBalance	The threshold for the network scatter value. When this value is reached, Hive starts balancing the load.	0.5
MaxNodeUsageToKick	The threshold for the node resource usage. When this value is reached, Hive starts emergency balancing.	0.9
ObjectImbalanceToBalance	The threshold for the database object imbalance metric.	0.02

Note

These parameters use relative values, where 1.0 represents 100% and effectively disables balancing. If the total hardware resource value can exceed 100%, adjust the ratio accordingly.

[14] Counter - a fake resource representing a count of tablets of a certain type on a node, used to ensure such tablets are distributed evenly across nodes.

Overloaded shards

Data shards serving row-oriented tables may become overloaded for the following reasons:

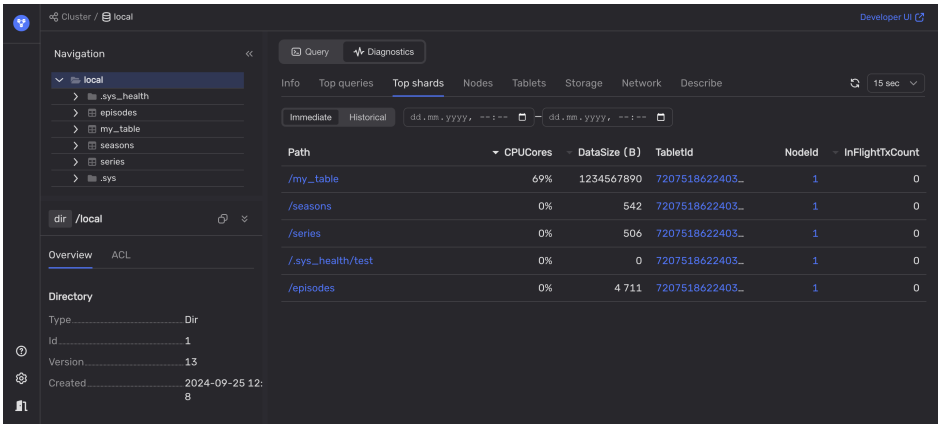
- A table is created without the AUTO_PARTITIONING_BY_LOAD clause.

  In this case, YDB does not split overloaded shards.

  Data shards are single-threaded and process queries sequentially. Each data shard can accept up to 10,000 operations. Accepted queries wait for their turn to be executed. So the longer the queue, the higher the latency.

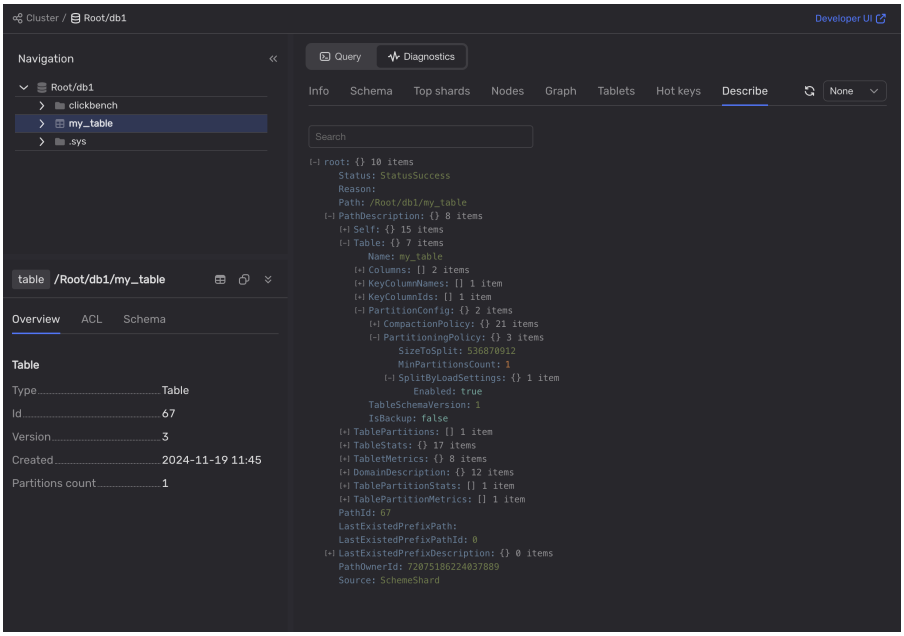
  If a data shard already has 10000 operations in its queue, new queries will return an "overloaded" error. Retry such queries using a randomized exponential back-off strategy. For more information, see Overloaded errors.
- A table was created with the AUTO_PARTITIONING_MAX_PARTITIONS_COUNT setting and has already reached its partition limit.
- An inefficient primary key that causes an imbalance in the distribution of queries across shards. A typical example is ingestion with a monotonically increasing primary key, which may lead to the overloaded "last" partition. For example, this could occur with an autoincrementing primary key using the serial data type.

Diagnostics



1. Use the YDB UI or Grafana to see if the YDB nodes are overloaded:
   - In the **DB overview** Grafana dashboard, analyze the **Overloaded shard count** chart.

The chart indicates whether the YDB cluster has overloaded shards, but it does not specify which table's shards are overloaded.



> **Tip**
>
> Use Grafana to set up alert notifications when YDB data shards get overloaded.

   - In the YDB UI:
     1. Go to the **Databases** tab and click on the database.
     2. On the **Navigation** tab, ensure the required database is selected.
     3. Open the **Diagnostics** tab.
     4. Open the **Top shards** tab.
     5. In the **Immediate** and **Historical** tabs, sort the shards by the **CPUCores** column and analyze the information.

Additionally, the information about overloaded shards is provided as a system table. For more information, see History of overloaded partitions.

2. To pinpoint the schema issue, use the YDB UI or YDB CLI:
   - In the YDB UI:
     1. On the **Databases** tab, click on the database.
     2. On the **Navigation** tab, select the required table.
     3. Open the **Diagnostics** tab.
     4. On the **Describe** tab, navigate to `root > PathDescription > Table > PartitionConfig > PartitioningPolicy`.

5. Analyze the **PartitioningPolicy** values:
   - `SizeToSplit`
   - `SplitByLoadSettings`
   - `MaxPartitionsCount`

   If the table does not have these options, see Recommendations for table configuration.

> **Note**
>
> You can also find this information on the **Diagnostics > Info** tab.

- In the YDB CLI:
  1. To retrieve information about the problematic table, run the following command:

     ```
     ydb scheme describe <table_name>
     ```

  2. In the command output, analyze the **Auto partitioning settings**:
     - `Partitioning by size`
     - `Partitioning by load`
     - `Max partitions count`

     If the table does not have these options, see Recommendations for table configuration.

3. Analyze whether primary key values increment monotonically:
   - Check the data type of the primary key column. `Serial` data types are used for autoincrementing values.
   - Check the application logic.
   - Calculate the difference between the minimum and maximum values of the primary key column. Then compare this value to the number of rows in a given table. If these values match, the primary key might be incrementing monotonically.

   If primary key values do increase monotonically, see Recommendations for the imbalanced primary key.

Recommendations

For table configuration

Consider the following solutions to address shard overload:

- If the problematic table is not partitioned by load, enable partitioning by load.

> **Tip**
>
> A table is not partitioned by load, if you see the `Partitioning by load: false` line on the **Diagnostics > Info** tab in the **YDB UI** or the `ydb scheme describe` command output.

- If the table has reached the maximum number of partitions, increase the partition limit.

> **Tip**
>
> To determine the number of partitions in the table, see the `PartCount` value on the **Diagnostics > Info** tab in the **YDB UI**.

Both operations can be performed by executing an `ALTER TABLE ... SET` query.

For the imbalanced primary key

Consider modifying the primary key to distribute the load evenly across table partitions. You cannot change the primary key of an existing table. To do that, you will have to create a new table with the modified primary key and then migrate the data to the new table.

> **Note**
>
> Also, consider changing your application logic for generating primary key values for new rows. For example, use hashes of values instead of values themselves.

Example

For a practical demonstration of how to follow these instructions, see Overloaded shard example.

Excessive tablet splits and merges

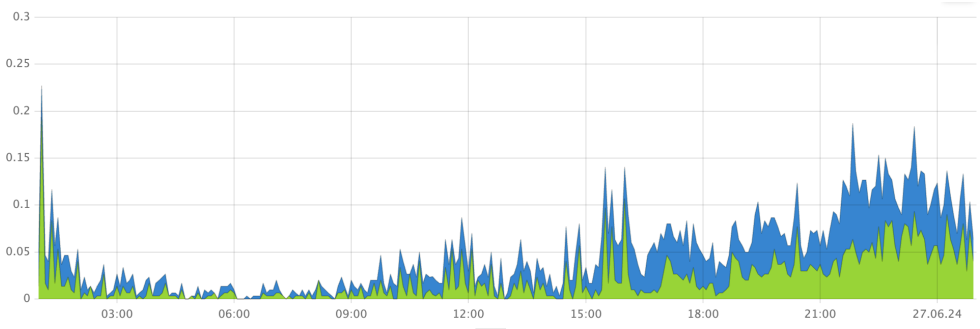
> **Warning**
>
> Supported only for row-oriented tables. Support for column-oriented tables is currently under development.

Each row-oriented table partition in YDB is processed by a data shard tablet. YDB supports automatic splitting and merging of data shards which allows it to seamlessly adapt to changes in workloads. However, these operations are not free and might have a short-term negative impact on query latencies.

When YDB splits a partition, it replaces the original partition with two new partitions covering the same range of primary keys. Now, two data shards process the range of primary keys that was previously handled by a single data shard, thereby adding more computing resources for the table.

By default, YDB splits a table partition when it reaches 2 GB in size. However, it's recommended to also enable partitioning by load, allowing YDB to split overloaded partitions even if they are smaller than 2 GB.

A scheme shard takes approximately 15 seconds to assess whether a data shard requires splitting. By default, the CPU usage threshold for splitting a data shard is set at 50%.

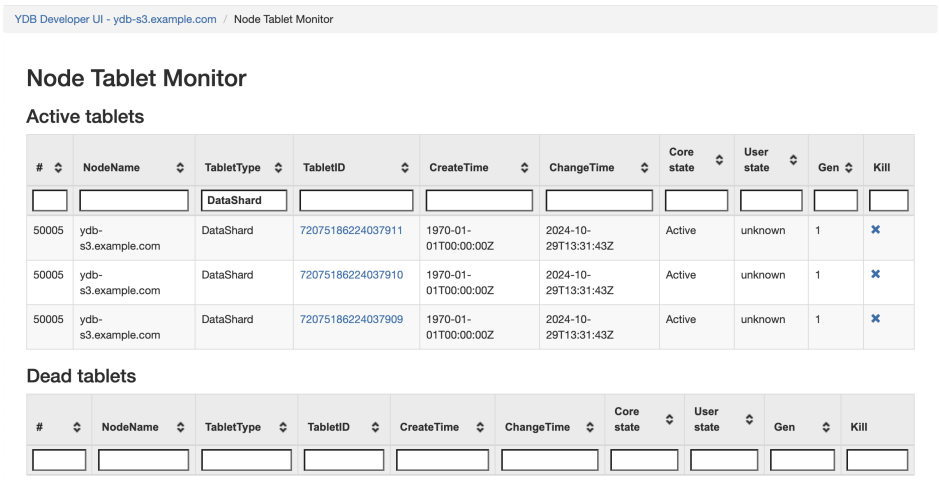


When YDB merges adjacent partitions in a row-oriented table, they are replaced with a single partition that covers their range of primary keys. TThe corresponding data shards are also consolidated into a single data shard to manage the new partition.

For merging to occur, data shards must have existed for at least 10 minutes, and their CPU usage over the last hour must not exceed 35%.

When configuring table partitioning, you can also set limits for the minimum and maximum number of partitions. If the difference between the minimum and maximum limits exceeds 20% and the table load varies significantly over time, Hive may start splitting overloaded tables and then merging them back during periods of low load.

Diagnostics



1. See if the **Split / Merge partitions** chart in the **DB status** Grafana dashboard shows any spikes.

```
This chart displays the time-series data for the following values:

- Number of split table partitions per second (blue)
- Number of merged table partitions per second (green)
```

2. Check whether the user load increased when the tablet splits and merges spiked.
   - Review the diagrams on the **DataShard** dashboard in Grafana for any changes in the volume of data read or written by queries.
   - Examine the **Requests** chart on the **Query engine** dashboard in Grafana for any spikes in the number of requests.
3. To identify recently split or merged tablets, follow these steps:
   3.1. In the YDB UI, click the **Developer UI** link in the upper right corner.
   3.2. Navigate to **Node Table Monitor** > **All tablets of the cluster**.
   3.3. To show only data shard tablets, in the **TabletType** filter, specify `DataShard`.

   3.4. Sort the tablets by the **ChangeTime** column and review tablets, which change time values coincide with the spikes on the **Split / Merge partitions** chart.
   3.5. To identify the table associated with the data shard, in the data shard row, click the link in the **TabletID** column.
   3.6. On the **Tablets** page, click the **App** link.

The information about the table is displayed in the **User table <table-name>** section.

4. To pinpoint the schema issue, follow these steps:

   4.1. Retrieve information about the problematic table using the YDB CLI. Run the following command:

   ```
   ydb scheme describe <table_name>
   ```

   4.2. In the command output, analyze the **Auto partitioning settings**:

   - `Partitioning by load`
   - `Max partitions count`
   - `Min partitions count`

Recommendations

If the user load on YDB has not changed, consider adjusting the gap between the min and max limits for the number of table partitions to the recommended 20% difference. Use the `ALTER TABLE table_name SET (key = value)` YQL statement to update the `AUTO_PARTITIONING_MIN_PARTITIONS_COUNT` and `AUTO_PARTITIONING_MAX_PARTITIONS_COUNT` parameters.

If you want to avoid splitting and merging data shards, you can set the min limit to the max limit value or disable partitioning by load.

Transaction lock invalidation

Transaction lock invalidation (TLI) occurs when one transaction (the breaker) writes data and breaks the optimistic locks of another transaction (the victim). The victim detects this at commit time and receives a `transaction locks invalidated` error. The transaction must be retried. Frequent retries degrade application performance.

> **Note**
>
> The YDB SDK provides a built-in mechanism for handling temporary failures. For more information, see Handling errors.

Preventing conflicts

- **Shorten transaction duration.** The longer a transaction holds locks, the higher the likelihood of a conflict. Where possible, avoid interactive transactions: the best approach is a single YQL query with `BEGIN;` and `COMMIT;` to read, modify, and commit data. If interactive transactions are necessary, execute `COMMIT` in the last query.
- **Reduce data overlap between transactions.** The fewer rows a transaction reads, the fewer locks it holds and the lower the chance of a conflict. Avoid reading unnecessary data. If multiple transactions compete for the same rows, reconsider your data model.
- **Use read-only transaction modes.** Transactions in `Snapshot Read-Only` mode read data from a consistent snapshot and do not acquire optimistic locks — such a transaction can never become a TLI victim. If a transaction does not modify data, explicitly set this mode in the SDK.

Example: transaction conflict during product reservation

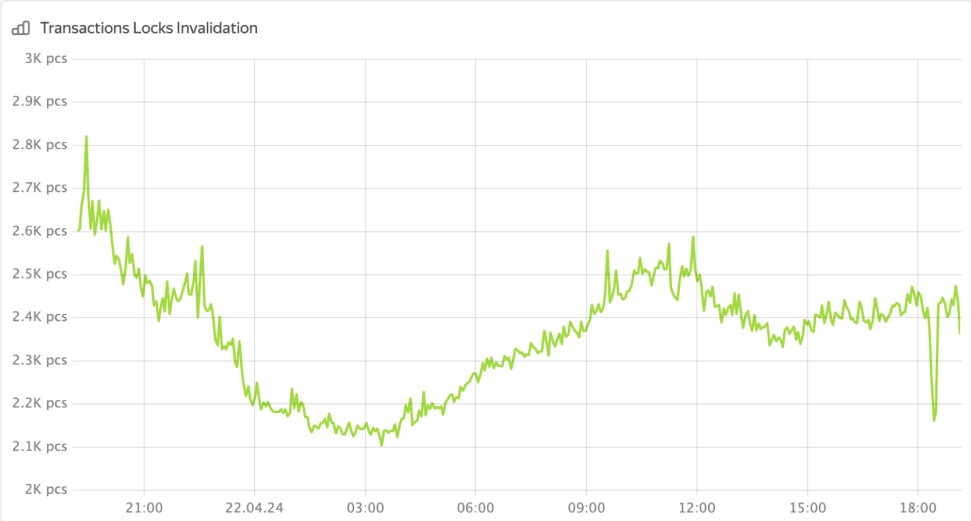
In an online store during a flash sale, hundreds of buyers may try to purchase the same product at the same time. A purchase transaction reads the current stock, then the application calculates discounts, waits for payment confirmation, and only after that decrements the stock:

```
SELECT available FROM stock WHERE sku = $sku AND warehouse_id = $warehouse_id;
-- application checks: available > 0
-- application calculates discounts, waits for payment ...
UPDATE stock SET available = available - 1 WHERE sku = $sku AND warehouse_id = $warehouse_id;
COMMIT;
```

The `SELECT` acquires an optimistic lock on the row. While the transaction is waiting for payment, another transaction may update the same row and commit. This invalidates the lock, and the first transaction fails at commit time with a TLI error.

The solution is to reserve the product immediately in a short transaction, and perform all slower operations afterwards (discount calculation, payment, external service calls):

```
BEGIN;
UPDATE stock SET available = available - 1, reserved = reserved + 1
WHERE sku = $sku AND warehouse_id = $warehouse_id AND available > 0;



UPSERT INTO orders (order_id, sku, qty, status)
VALUES ($order_id, $sku, 1, "RESERVED");
COMMIT;
-- afterwards: calculate discounts, process payment, arrange delivery
```

If the payment succeeds, a separate transaction sets `status = "PAID"`. If it fails, another short transaction moves the item from `reserved` back to `available` and sets the status to `"CANCELLED"`. Because the reservation transaction completes quickly, it minimizes the time locks are held and reduces the probability of conflicts.

Diagnostics

Monitoring in Grafana

1. Open the **DB overview** Grafana dashboard.
2. See if the **Transaction Lock Invalidation** chart shows any spikes.

This chart shows the number of queries that returned the "transaction locks invalidated" error per second.

Diagnostics via TLI logs

When a transaction fails with a TLI error, the error message contains the victim query identifier:

```
Transaction locks invalidated. ... VictimQuerySpanId: 1111111111111111.
```

Using this `VictimQuerySpanId`, you can find the full conflict context in the server logs: which query acquired the locks and which one broke them. For details on enabling logging, log entry format, event correlation, and the `find_tli_chain` utility for automated log analysis, see TLI Logging.

Analysis via system views

The following system views are available for analyzing lock conflicts:

Query-level analysis

To identify queries with the most conflicts, use the `.sys/query_metrics_one_minute` system view:

```
SELECT QueryText, LocksBrokenAsBreaker, LocksBrokenAsVictim
FROM `.sys/query_metrics_one_minute`
WHERE LocksBrokenAsBreaker > 0 OR LocksBrokenAsVictim > 0
ORDER BY LocksBrokenAsBreaker + LocksBrokenAsVictim DESC;
```

Column	Description
`LocksBrokenAsBreaker`	How many times this query broke other transactions' locks
`LocksBrokenAsVictim`	How many times this query's locks were broken

Queries with a high `LocksBrokenAsBreaker` are breakers: they cause other transactions to roll back. Queries with a high `LocksBrokenAsVictim` are victims.

Partition-level analysis

To analyze broken locks at the table partition level, use the following system views:

- `.sys/partition_stats` — current partition statistics, contains the cumulative `LocksBroken` field
- `.sys/top_partitions_by_tli_one_minute` — top 10 partitions with non-zero broken locks for one-minute intervals
- `.sys/top_partitions_by_tli_one_hour` — top 10 partitions with non-zero broken locks for one-hour intervals

Example query to find partitions with the most broken locks:

```
SELECT
    Path,
    SUM(LocksBroken) as TotalLocksBroken
FROM `.sys/partition_stats`
GROUP BY Path
ORDER BY TotalLocksBroken DESC
LIMIT 10;
```

Example query to view the history of broken locks by partition:

```
SELECT
    IntervalEnd,
    LocksBroken,
    Path
FROM `.sys/top_partitions_by_tli_one_hour`
WHERE IntervalEnd BETWEEN Timestamp("2000-01-01T00:00:00Z") AND Timestamp("2099-12-31T00:00:00Z")
ORDER BY IntervalEnd DESC, LocksBroken DESC
LIMIT 100;
```

TLI Logging

Transaction lock invalidation (`TLI`) logging lets you identify which query had its locks broken **(the victim)** and which query broke them **(the breaker)**.

Enabling Logging

To get detailed logs about lock conflicts, set the `INFO` level (numeric value `6`) for the `TLI` component.

Add the following to the cluster configuration:

```
log_config:
  entry:
    - component: "TLI"
      level: 6  # INFO
```

The `log_config` parameter supports dynamic updates without node restarts.

Once enabled, the server writes logs on every broken lock, and `VictimQuerySpanId` begins appearing in SDK error messages.

> **Note**
>
> The base log size for a single `TLI` event is 10–20 KB. The actual volume depends on the size of the text of the logged queries (the breaker and the victim) and the transactions of which they are part, since all this data is recorded in the log. If conflicts are infrequent, the logging overhead is negligible. At high `TLI` rates, the total log volume can be significant.
>
> To exclude tables with expected conflicts from `TLI` diagnostics, use the `tli_config.ignored_table_regexes` parameter.

Log Structure

When `TLI` occurs, the server writes log entries from each component (`DataShard` or `SessionActor`) for each side of the conflict (victim or breaker). The number of entries depends on the number of queries in the transactions.

Example scenario:

Two sessions are established to the DBMS: victim and breaker.

Time	QuerySpanId	Role	Query
T1	`1111111111111111`	Victim	`SELECT * FROM Orders WHERE OrderId = 42` (acquires lock)
T2	`2222222222222222`	Breaker	`UPDATE Orders SET Status = 'done' WHERE OrderId = 42` (breaks lock)
T3	`3333333333333333`	Victim	`UPDATE Orders SET Amount = 100 WHERE OrderId = 42` (commit fails)

> **Note**
>
> In the log content examples below, the order of individual fields within entries may differ.

Breaker log (DataShard):

```
component=DataShard tabletId=<tablet-id> message="Write transaction broke other locks" breakerQuerySpanId=222
2222222222222 victimQuerySpanId=1111111111111111
```

Breaker log (SessionActor):

```
component=SessionActor message="Query had broken other locks" breakerTxSpanId=2222222222222222 querySpanId=22
22222222222222 queryText="UPDATE Orders SET Status = 'done' WHERE OrderId = 42"
```

Victim log (DataShard):

```
component=DataShard tabletId=<tablet-id> message="Write transaction was a victim of broken locks" victimQuery
SpanId=1111111111111111
```

Victim log (SessionActor):

In this example, SessionActor writes two entries — one for each query of the victim transaction:

```
component=SessionActor message="Query was a victim of broken locks" victimTxSpanId=1111111111111111 querySpan
Id=1111111111111111 queryText="SELECT * FROM Orders WHERE OrderId = 42"

component=SessionActor message="Query was a victim of broken locks" victimTxSpanId=1111111111111111 querySpan
Id=3333333333333333 queryText="UPDATE Orders SET Amount = 100 WHERE OrderId = 42"
```

Log Fields

Field	Description	Where it appears
`component`	Source of the entry: `DataShard` or `SessionActor`	All `TLI` logs
`message`	Event type (see examples above)	All `TLI` logs

`tabletId`	Identifier of the DataShard tablet	DataShard logs
`victimQuerySpanId`	Identifier of the query whose locks were broken	Victim DataShard logs, breaker DataShard logs
`breakerQuerySpanId`	Identifier of the query that broke the locks	Breaker DataShard logs
`victimTxSpanId`	Identifier of the victim query whose locks were broken. Matches victimQuerySpanId in DataShard logs.	Victim SessionActor logs
`breakerTxSpanId`	Identifier of the breaker query that broke the locks. Matches breakerQuerySpanId in DataShard logs.	Breaker SessionActor logs
`querySpanId`	Identifier of a specific query in the SessionActor entry	SessionActor logs
`queryText`	SQL of a specific query in the SessionActor entry	SessionActor logs

Log Analysis

Using the `VictimQuerySpanId` from the SDK error message, you can find all related events:

1. **Find the victim query ID**: in the victim log, the `victimQuerySpanId` field contains the ID of the `SELECT` query that acquired the broken locks.
2. **Find the victim query text**: in the victim log, there is an entry whose `victimTxSpanId` matches `querySpanId`. The `queryText` field of this entry contains the text of the `SELECT` query that acquired the broken locks.
3. **Find the breaker query ID**: in the breaker DataShard log, there is an entry whose `victimQuerySpanId` field contains the same value (the victim query ID). From this entry, take the value of `breakerQuerySpanId`, which is the breaker query ID.
4. **Find the breaker query text**: in the breaker log, there is an entry whose `breakerTxSpanId` contains the breaker query ID and at the same time matches `querySpanId`. The `queryText` field of this entry contains the text of the breaker query.
5. **Get full transaction context**: all SessionActor entries with the same `victimTxSpanId` contain information about the queries of the victim transaction. Similarly, all SessionActor entries with the same `breakerTxSpanId` contain information about the queries of the breaker transaction.

find_tli_chain Utility

For automatic `TLI` log analysis, the YDB repository includes the `find_tli_chain.py` utility.

This utility takes the following parameters:

- `VictimQuerySpanId` - identifier of the broken query from the SDK error message;
- `LogFile` - name of the log file for log analysis.

It is assumed that `TLI` logging was previously enabled in the configuration, log files were collected from database nodes and merged into one file.

```
python3 find_tli_chain.py <VictimQuerySpanId> <LogFile>
```

Example:

```
python3 find_tli_chain.py 1111111111111111 ydb.log
```

```
================================================
  TLI Chain
================================================

VictimQuerySpanId: 1111111111111111

VictimQueryText: SELECT * FROM Orders WHERE OrderId = 42

BreakerQuerySpanId: 2222222222222222

BreakerQueryText: UPDATE Orders SET Status = 'done' WHERE OrderId = 42

================================================
  VictimTx
================================================

SELECT * FROM Orders WHERE OrderId = 42

UPDATE Orders SET Amount = 100 WHERE OrderId = 42

================================================
  BreakerTx
================================================

UPDATE Orders SET Status = 'done' WHERE OrderId = 42
```

The utility outputs:

- **TLI Chain** — `VictimQuerySpanId`, `VictimQueryText`, `BreakerQuerySpanId`, `BreakerQueryText`;
- **VictimTx** — all queries of the victim transaction;
- **BreakerTx** — all queries of the breaker transaction.

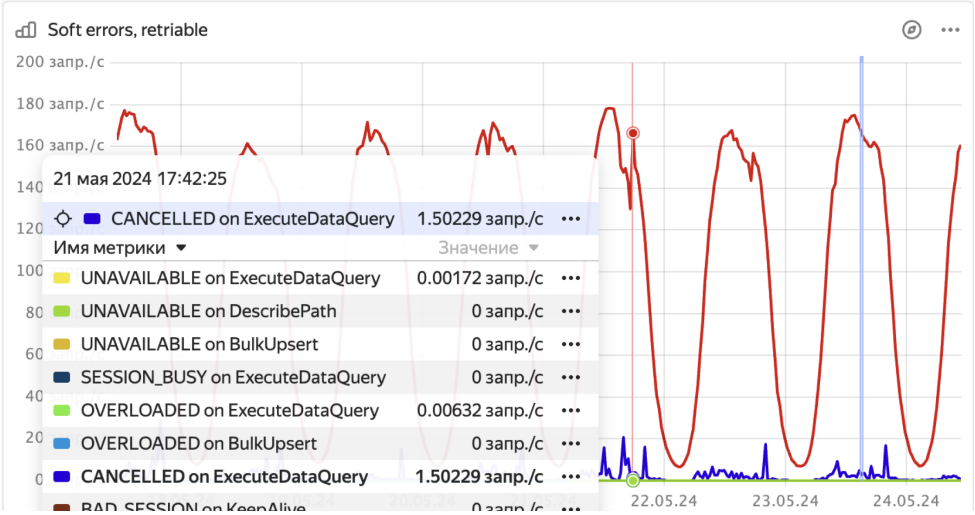
Additional parameters:

Parameter	Description

`--window-sec N`	Time window for searching around the event (default: 10 s)
`--no-color`	Disable colored output

Note

The utility correctly handles unsorted and mixed log files: filtering is based on timestamp values, not line positions.



Overloaded errors

YDB returns `OVERLOADED` errors in the following cases:

- Overloaded table partitions with over 15000 queries in their queue.
- The outbound CDC queue exceeds the limit of 10000 elements or 125 MB.
- Table partitions in states other than normal, for example partitions in the process of splitting or merging.
- The number of sessions with a YDB node has reached the limit of 1000.

Diagnostics

1. Open the **DB overview** Grafana dashboard.
2. In the **API details** section, see if the **Soft errors (retriable)** chart shows any spikes in the rate of queries with the `OVERLOADED` status.

3. To check if the spikes in overloaded errors were caused by exceeding the limit of 15000 queries in table partition queues:
   3.1. In the YDB UI, go to the **Databases** tab and click on the database.
   3.2. On the **Navigation** tab, ensure the required database is selected.
   3.3. Open the **Diagnostics** tab.
   3.4. Open the **Top shards** tab.
   3.5. In the **Immediate** and **Historical** tabs, sort the shards by the **InFlightTxCount** column and see if the top values reach the 15000 limit.
4. To check if the spikes in overloaded errors were caused by tablet splits and merges, see Excessive tablet splits and merges.
5. To check if the spikes in overloaded errors were caused by exceeding the 1000 limit of open sessions, in the Grafana **DB status** dashboard, see the **Session count by host** chart.
6. See the overloaded shards issue.

Recommendations

If a YQL query returns an `OVERLOADED` error, retry the query using a randomized exponential backoff strategy. The YDB SDK provides a built-in mechanism for handling temporary failures. For more information, see Handling errors.

Exceeding the limit of open sessions per node may indicate a problem in the application logic.

Retry cascade effect

A cascade effect occurs when a client starts frequently retrying queries whose execution time exceeds the configured timeout.

Mechanism

Query execution time exceeds client timeout. Client starts repeating requests, but original queries continue executing on the server. Each subsequent retry takes longer than the previous one as the server processes more concurrent requests. At some point, query latency permanently exceeds client timeout. Client continues retrying, increasing load and further raising latency.

YDB specifics

In YDB's actor model, canceling in-flight requests has limitations. This is especially evident with client timeouts - when a client closes the gRPC stream before receiving a response, the request may continue executing on the server.

Recovery

A shard can recover normal operation only through temporary complete load removal, shard restart, or load-based shard splitting.

Recommendations

Avoid retrying timeouts or use them with caution. Apply exponential backoff with sufficiently large delays. Ensure the load actually decreases before retrying. Aggressive retries in an overloaded state have the opposite effect - the load on the shard increases by times.
For more information on proper error handling, see Handling errors.

Spilling Troubleshooting

This section provides troubleshooting information for common spilling issues in YDB. Spilling is a memory management mechanism that temporarily saves intermediate computation data to disk when the system runs out of RAM. These errors can occur during query execution when the system attempts to use spilling functionality and can be observed in logs and query responses.

Common Issues

- Permission denied - Insufficient access permissions to the spilling directory
- Spilling Service not started - Attempt to use spilling when the Spilling Service is disabled
- Total size limit exceeded - Maximum total size of spilling files exceeded

See Also

- Spilling Configuration
- Spilling Concept
- Memory Controller Configuration
- YDB Monitoring
- Performance Diagnostics

Permission Denied

Insufficient access permissions to the spilling directory prevent YDB from writing data to disk during spilling operations. This can cause queries to fail when they require spilling to handle large data volumes.

Diagnostics

Check if the spilling directory exists and has proper permissions:

- Verify that the spilling directory exists (see Spilling Configuration for information on how to find the spilling directory)
- Ensure the directory has read and write permissions for the user under which `ydbd` is running
- Check access permissions to the spilling directory
- Verify that the user under which `ydbd` runs can read and write to the directory

Recommendations

If permissions are incorrect:

1. Change the directory owner to the user under which `ydbd` runs.
2. Ensure read/write permissions are set for the directory owner.
3. Restart the `ydbd` process to apply the changes.

> **Note**
>
> The spilling directory is automatically created by YDB when the process starts. If the directory doesn't exist, check that the `root` parameter in the spilling configuration is set correctly.

Spilling Service Not Started

Spilling is disabled, but the system ran out of memory during query execution. When spilling is disabled, YDB cannot offload intermediate data to disk, which leads to query failure when available memory is exhausted.

Diagnostics

Check the spilling service configuration:

- Verify that `table_service_config.spilling_service_config.local_file_config.enable` is set to `true`.

Recommendations

To fix this error, enable spilling:

1. Set `table_service_config.spilling_service_config.local_file_config.enable`: `true` in your configuration.

For more details on enabling spilling, see the Enable section.

> **Note**
>
> Read more about the spilling architecture in Spilling in YDB.

Total Size Limit Exceeded

The maximum total size of spilling files has been exceeded (parameter `max_total_size`). This occurs when the total size of all spilling files reaches the configured limit, preventing new spilling operations.

Diagnostics

Check the current spilling usage:

- Monitor the total size of spilling files in the spilling directory.
- Check the current value of the `max_total_size` parameter.
- Review available disk space in the spilling directory location.
- Check if there are any stuck spilling files that should have been cleaned up.

Recommendations

To resolve this issue:

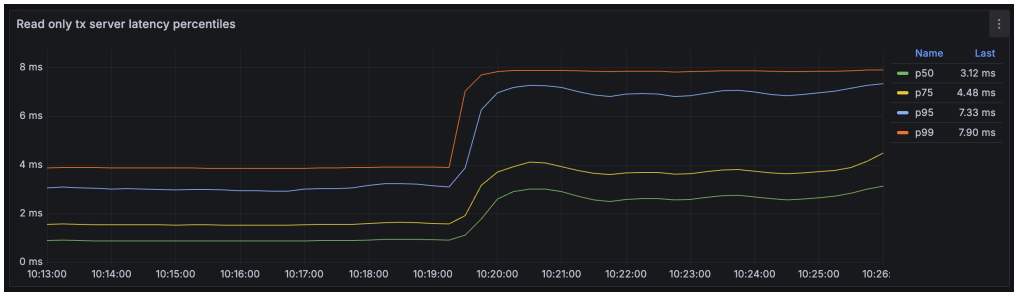
1. **Increase the spilling size limit:**
   - If there is sufficient free disk space, increase the `max_total_size` parameter in the configuration.
   - Increase the value by 20–50% from the current one.
2. **Expand disk space:**
   - If there is insufficient free disk space, add additional disk space.
   - Ensure that the spilling directory is located on a disk with sufficient capacity.
3. **Try repeating the query:**
   - Wait for other resource-intensive queries to complete.
   - Repeat the query execution during less busy times.

Overloaded shard example

This article describes an example of how to diagnose overloaded shards and resolve the issue.

For more information about overloaded shards and their causes, see Overloaded shards.

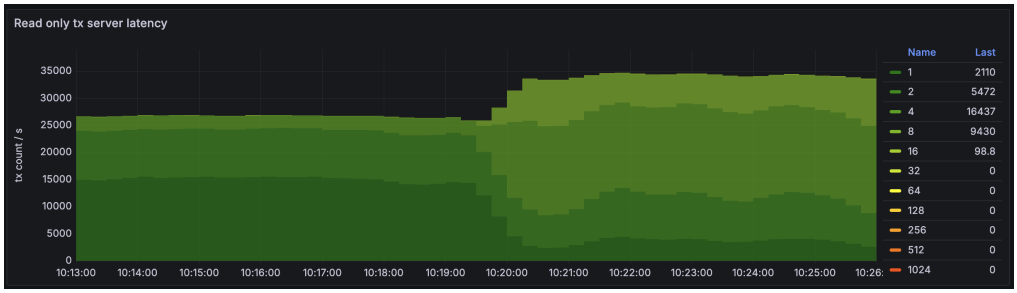
The article begins by stating the problem. Then, we'll examine diagrams in Grafana and information on the **Diagnostics** tab in the YDB UI to solve the problem and observe the solution in action.



At the end of the article, you can find the steps to reproduce the situation.

Initial issue

You were notified that your system has started taking too long to process user requests.



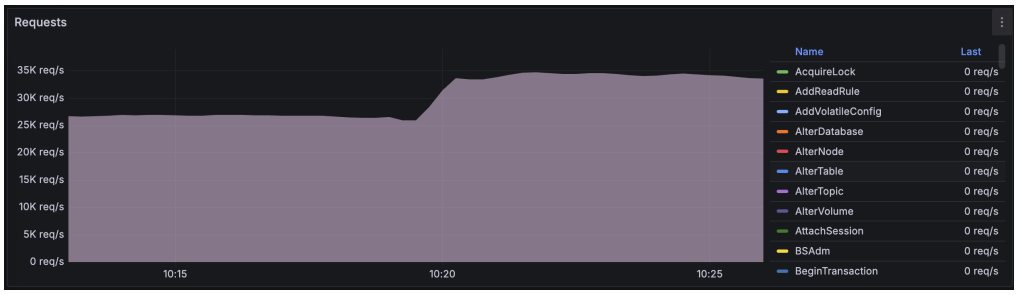
> **Note**
>
> These requests access a row-oriented table, which is managed by data shards.

Let's examine the **Latency** diagrams in the DB overview Grafana dashboard to determine whether the problem is related to the YDB cluster:

See the diagram description

The diagram shows transaction latency percentiles. At approximately `10:19:30`, these values increased by two to three times.

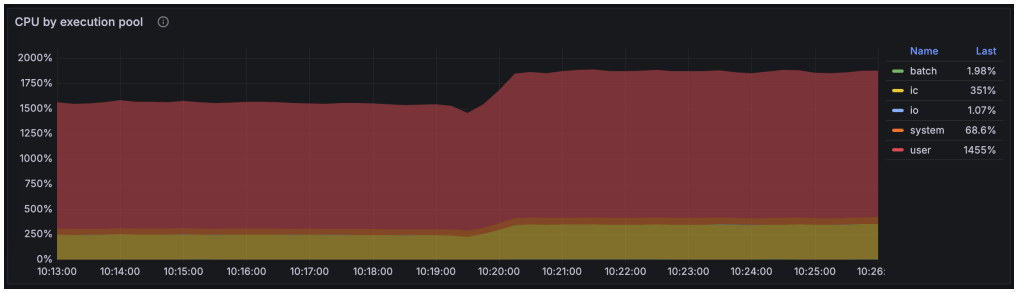
See the diagram description



The diagram shows a heatmap of transaction latencies. Transactions are grouped into buckets based on their latency, with each bucket represented by a different color. This diagram displays both the number of transactions processed by YDB per second (on the vertical axis) and the latency distribution among them (with color).

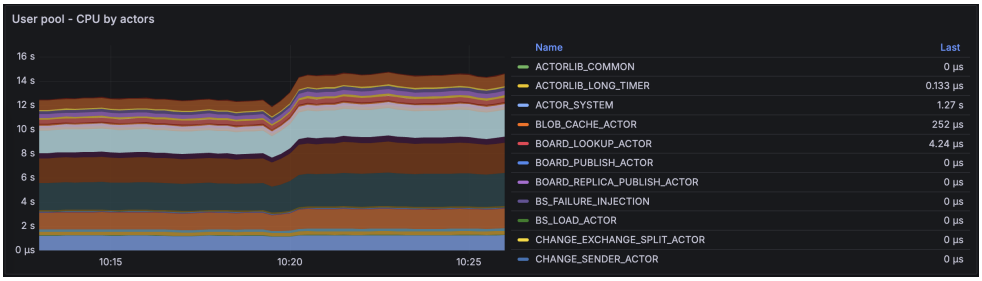
By `10:20:30`, the share of transactions with the lowest latencies (`Bucket 1`, dark green) had dropped by four to five times. `Bucket 4` grew by approximately five times, and a new group of slower transactions, `Bucket 8`, appeared.

Indeed, the latencies have increased. Now, we need to localize the problem.

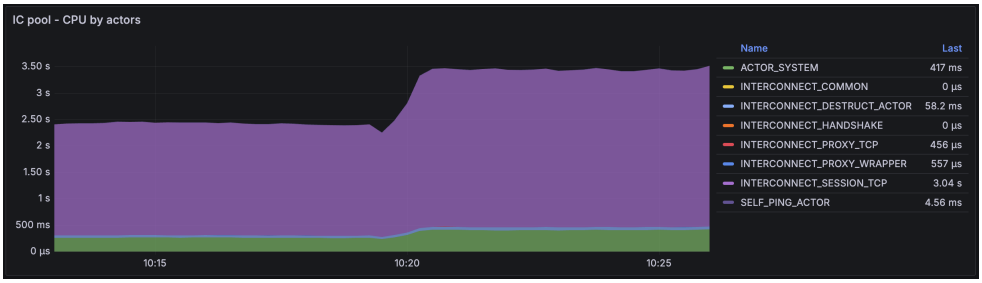


Diagnostics

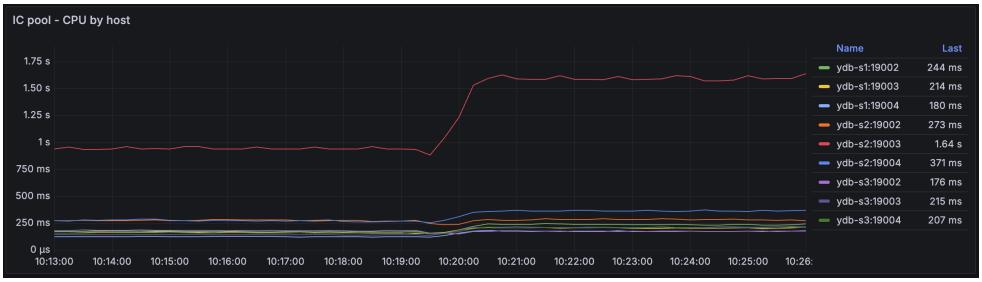
Let's determine why the latencies increased. Could the cause be an increased workload? Here is the **Requests** diagram from the **API details** section of the DB overview Grafana dashboard:



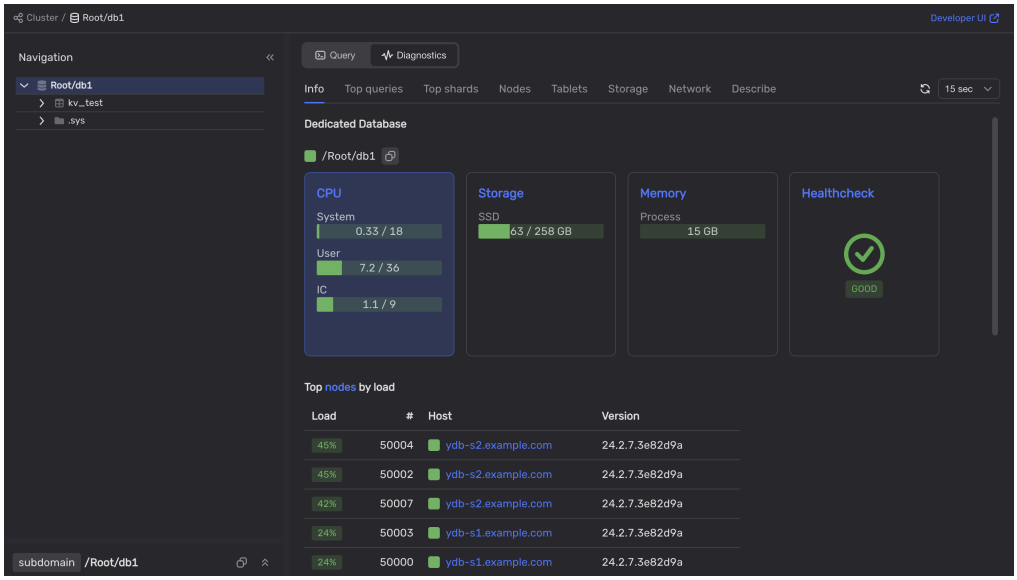
The number of user requests increased from approximately 27,000 to 35,000 at around `10:20:00`. But can YDB handle the increased load without additional hardware resources?



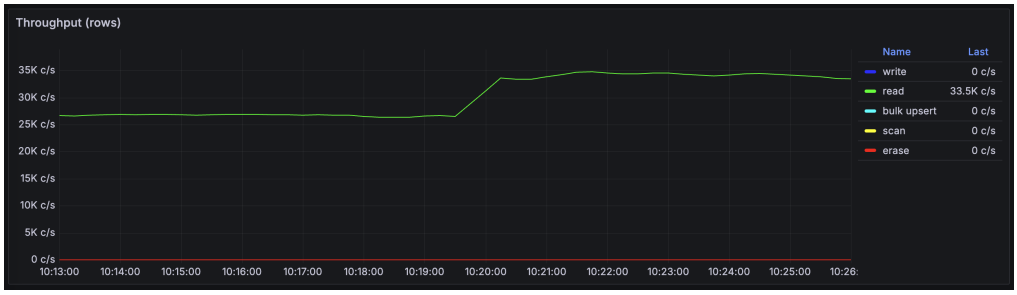
The CPU load has increased, as shown in the **CPU by execution pool** diagram.



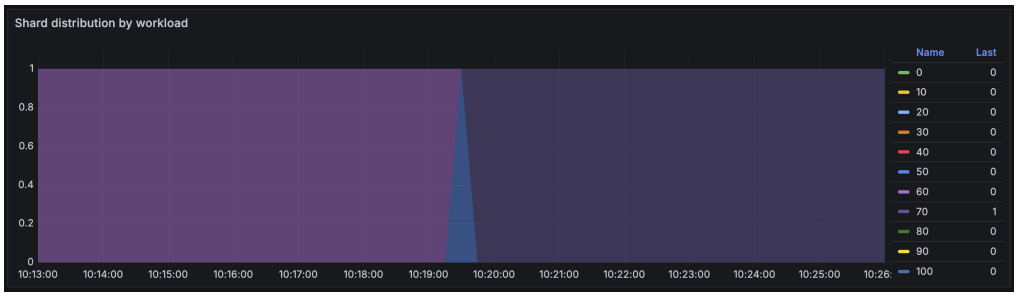
See the details on the CPU Grafana dashboard



Examining the **CPU** Grafana dashboard reveals that CPU usage increased in the user pool and the interconnect pool:



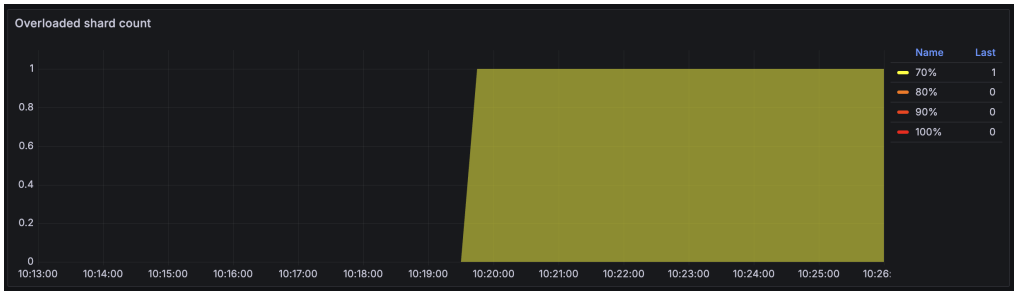
We can also observe overall CPU usage on the **Diagnostics** tab of the YDB UI:



The YDB cluster appears not to utilize all of its CPU capacity.

By inspecting the **DataShard** and **DataShard details** sections of the DB overview Grafana dashboard, we can see that after the cluster load increased, one of its data shards became overloaded.

See the diagram description

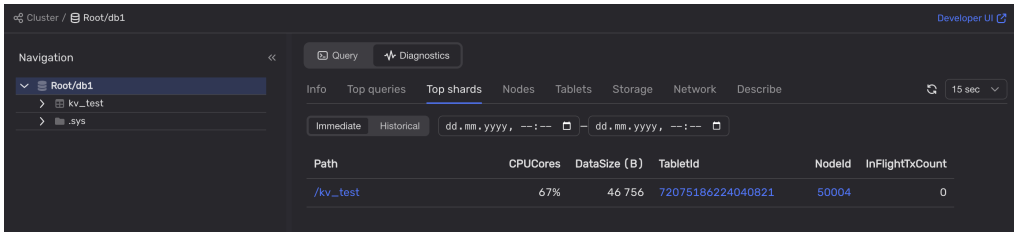


This diagram shows that the number of rows read per second in the YDB database increased from approximately 26,000 to 33,500 rows per second.

See the diagram description

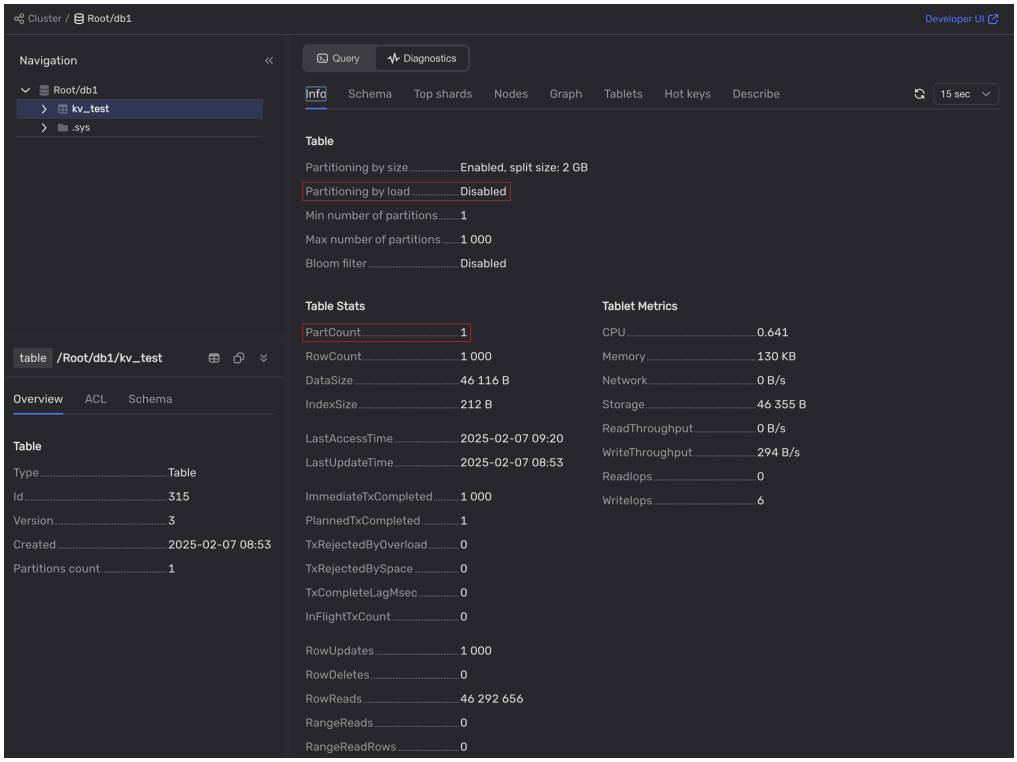
This diagram shows a heatmap of data shard distribution by workload. Data shards are grouped into ten buckets based on the ratio of their current workload to full computing capacity. This allows you to see how many data shards your YDB cluster currently runs and how loaded they are.

The diagram shows only one data shard whose workload changed at approximately `10:19:30`—the data shard moved to `Bucket 70`, which contains shards loaded to between 60% and 70% of their capacity.



See the diagram description

Similar to the previous diagram, the **Overloaded shard count** is a heatmap of data shard distribution by load. However, it displays only data shards with a workload exceeding 60%.



This diagram shows that the workload on one data shard increased to 70% at approximately `10:19:30`.

To determine which table the overloaded data shard is processing, let's open the **Diagnostics > Top shards** tab in the YDB UI:

We can see that one of the data shards processing queries for the `kv_test` table is loaded at 67%.

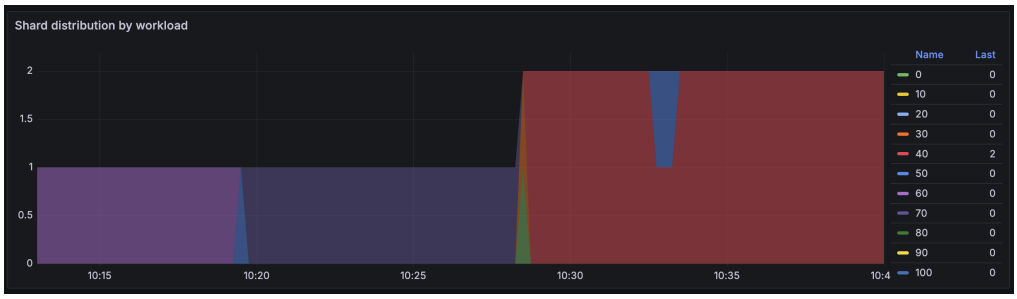
Next, let's examine the `kv_test` table on the **Info** tab:

Warning

The `kv_test` table was created with partitioning by load disabled and has only one partition.

This means that a single data shard processes all requests to this table. Since data shards are single-threaded and thus can handle only one request at a time, this is a poor practice.

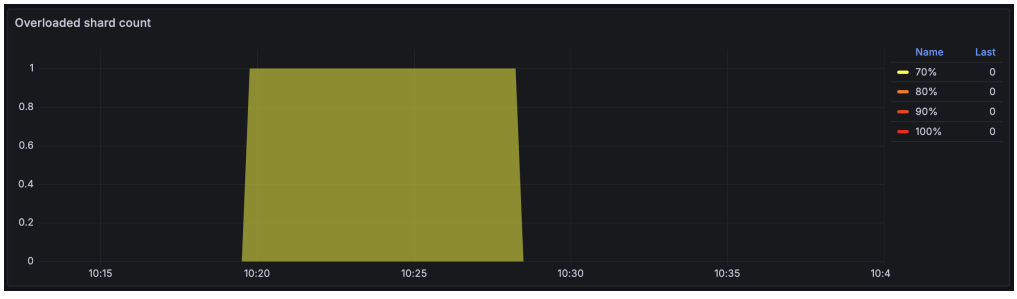
Solution



We should enable partitioning by load for the `kv_test` table:

1. In the YDB UI, select the database.
2. Open the **Query** tab.
3. Run the following query:

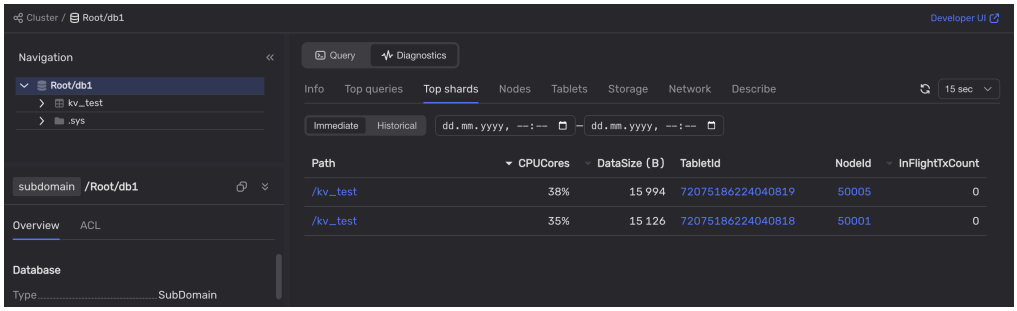
```
ALTER TABLE kv_test SET (
    AUTO_PARTITIONING_BY_LOAD = ENABLED
);
```



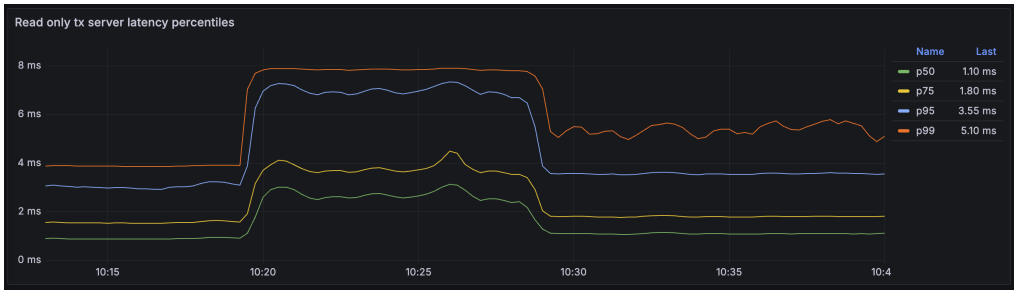
Aftermath

When we enable automatic partitioning for the `kv_test` table, the overloaded data shard splits into two.

See the diagram description



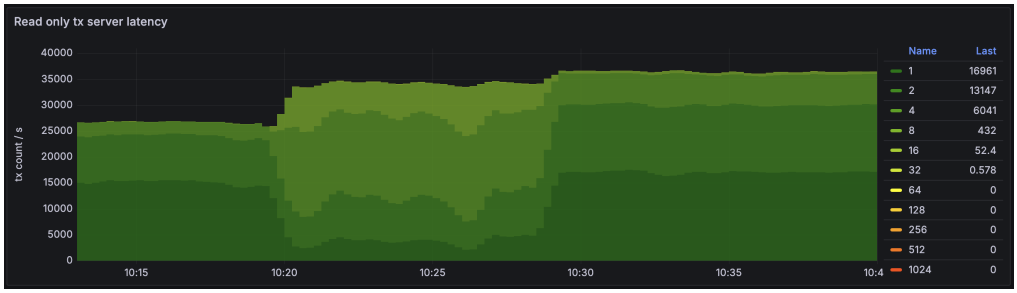
The diagram shows that the number of data shards increased at about `10:28:00`. Based on the bucket color, their workload does not exceed 40%.



See the diagram description

The overloaded shard disappeared from the diagram at approximately `10:28:00`.

Now, two data shards are processing queries to the `kv_test` table, and neither is overloaded:



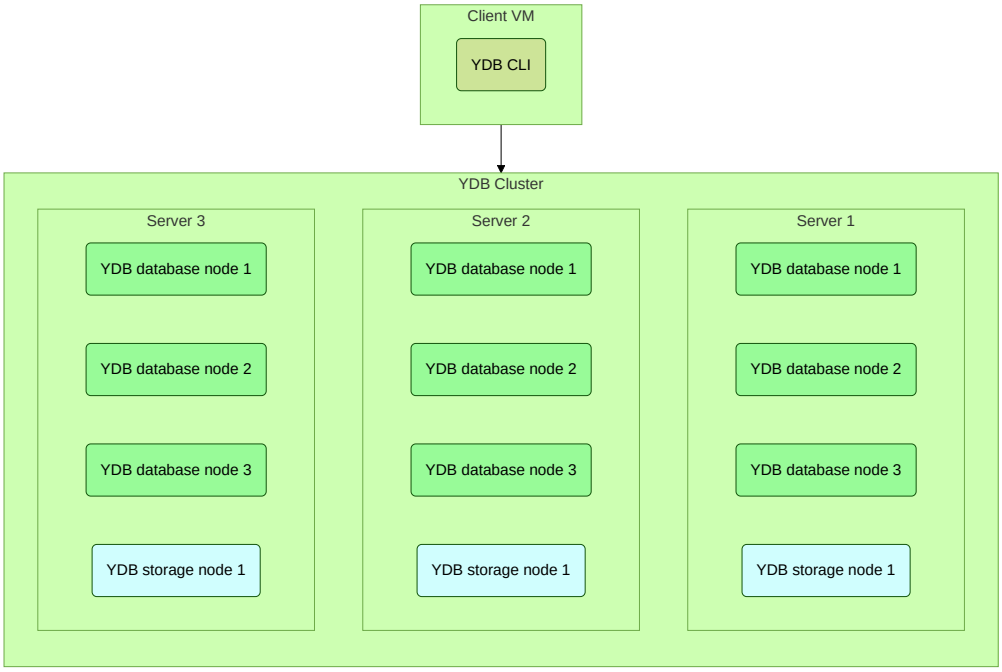
Let's confirm that latencies have returned to normal:

See the diagram description

At approximately `10:28:00`, the p50, p75, and p95 latency percentiles dropped almost to their original levels. The decrease in p99 latency is less pronounced but still shows a twofold reduction.

See the diagram description

The diagram shows that transactions are now grouped into six buckets. Approximately half of the transactions have returned to `Bucket 1`, meaning their latency is less than one millisecond. More than a third of the transactions are in `Bucket 2`, with latencies between one and two milliseconds. One-sixth of the transactions are in `Bucket 4`. The sizes of the other buckets are insignificant.



The latencies are almost as low as they were before the workload increased. We did not increase the system costs by introducing additional hardware resources. We've only enabled automatic partitioning by the load, which allowed us to use the existing resources more efficiently.

Bucket name	Latencies, ms	Single overloaded data shard, transactions per second	Multiple data shards, transactions per second
1	0-1	2110	▲ 16961
2	1-2	5472	▲ 13147
4	2-4	16437	▼ 6041
8	4-8	9430	▼ 432
16	8-16	98.8	▼ 52.4
32	16-32	—	▲ 0.578

Testbed

Topology

For this example, we used a YDB cluster consisting of three servers running Ubuntu 22.04 LTS. Each server runs one storage node and three database nodes belonging to the same database.

Hardware configuration

The servers are virtual machines with the following computing resources:

- Platform: Intel Broadwell
- Guaranteed vCPU performance: 100%
- vCPU: 28
- RAM: 32 GB
- Storage:
  - 3 x 93 GB SSD per storage node
  - 20 GB HDD for the operating system

Test

The load on the YDB cluster was generated using the `ydb workload` CLI command. For more information, see Load testing.

To reproduce the load, follow these steps:

1. Initialize the tables for the workload test:

   ```
   ydb workload kv init --min-partitions 1 --auto-partition 0
   ```

   We deliberately disable automatic partitioning for the created tables by using the `--min-partitions 1 --auto-partition 0` options.

2. Emulate the standard workload on the YDB cluster:

   ```
   ydb workload kv run select -s 600 -t 100
   ```

   We ran a simple load type using a YDB database as a key-value storage. Specifically, we used the `select` load to create SELECT queries and retrieve rows based on an exact match of the primary key.

   The `-t 100` parameter is used to run the test in 100 threads.

3. Overload the YDB cluster:

   ```
   ydb workload kv run select -s 1200 -t 250
   ```

   As soon as the first test ended, we ran the same load test in 250 threads to simulate the overload.

General questions about YDB

What is YDB?

YDB is a distributed fault-tolerant SQL DBMS. YDB offers high availability and scalability, while ensuring strong consistency and support for ACID transactions. Queries are made using an SQL dialect (YQL).

YDB is a fully managed database. DB instances are created through the YDB database management service.

What features does YDB provide?

YDB provides high availability and data security through synchronous replication in three availability zones. YDB also ensures even load distribution across available hardware resources. This means you don't need to order resources, YDB automatically provisions and releases resources based on the user load.

What consistency model does YDB use?

To read data, YDB uses a model of strict data consistency.

How do I design a primary key?

To design a primary key properly, follow the rules below.

- Avoid situations where most of the load falls on a single partition of a table. With even load distribution, it's easier to achieve high overall performance.This rule implies that you shouldn't use a monotonically increasing sequence, such as timestamp, as a table's primary key.
- The fewer table partitions a query uses, the faster it runs. For greater performance, follow the one query — one partition rule.
- Avoid situations where a small part of the DB is under much heavier load than the rest of the DB.

For more information, see choosing a primary key.

How do I evenly distribute load across table partitions?

You can use the following techniques to distribute the load evenly across table partitions and increase overall DB performance.

- To avoid using uniformly increasing primary key values, you can:
  - Change the order of its components.
  - use a hash of the key column values as the primary key.
- Reduce the number of partitions used in a single query.

For more information, see choosing a primary key.

Can I use NULL in a key column?

In YDB, all columns, including key ones, may contain a `NULL` value, but we don't recommend using `NULL` as values in key columns.

Per the SQL standard (ISO/IEC 9075), you can't compare `NULL` with other values. Therefore, the use of concise SQL statements with simple comparison operators may result in rows containing NULL being skipped during filtering, for example.

Is there an optimal size of a database row?

To achieve high performance, we don't recommend writing rows larger than 8 MB and key columns larger than 2 KB to the DB.

For more information about limits, see Database limits.

How are secondary indexes used in YDB?

Secondary indexes in YDB are global and can be non-unique.

For more information, see Secondary indexes.

How are paginated results printed?

To print paginated results, we recommend selecting data sorted by primary key sequentially, limiting the number of rows with the `LIMIT` keyword. We do not recommend using the `OFFSET` keyword to solve this problem.

For more information, see Paginated results.

How do I delete expired data?

To efficiently delete outdated data, we recommend using TTL.

Syncing two data centers in geographically distributed clusters

The lead tablet writes data to a distributed network storage that saves copies to several data centers. YDB does not commit a user query until after the required number of copies are saved to the required number of data centers.

SDK

What should I do if the SDK crashes when shutting down an application?

Make sure not to wrap SDK components in a singleton, since their lifetime shouldn't exceed the execution time of the `main()` function. When a client is destroyed, session pools are emptied, so network navigation is required. But gRPC contains global static variables that might already be destroyed by this time. This disables gRPC. If you need to declare a driver as a global object, invoke the `Stop(true)` function on the driver before exiting the `main()` function.

What should I do if, when using a `fork()` system call, a program does not work properly in a child process?

Using `fork()` in multithreaded applications is an antipattern. Since both the SDK and the gRPC library are multithreaded applications, their stability is not guaranteed.

What do I do if I get the "Active sessions limit exceeded" error even though the current number of active sessions is within limits?

The limit applies to the number of active sessions. An active session is a session passed to the client to be used in its code. A session is returned to the pool in a destructor. In this case, the session itself is a replicated object. You may have saved a copy of the session in the code.

Is it possible to make queries to different databases from the same application?

Yes, the C++ SDK lets you override the DB parameters and token when creating a client. There is no need to create separate drivers.

What should I do if a VM has failed and it's impossible to make a query?

To detect that a VM is unavailable, set a client timeout. All queries contain the client timeout parameters. The timeout value should be an order of magnitude greater than the expected query execution time.

Errors

Possible causes for "Status: OVERLOADED Error: Pending previous query completion" in the C++ SDK

Q: When running two queries, I try to get a response from the future method of the second one. It returns: `Status: OVERLOADED Why: <main>: Error: Pending previous query completion`.

A: Sessions in the SDK are single-threaded. To run multiple queries at once, you need to create multiple sessions.

What do I do if I frequently get the "Transaction locks invalidated" error?

Typically, if you get this error, repeat a transaction, as YDB uses optimistic locking. If this error occurs frequently, this is the result of a transaction reading a large number of rows or of many transactions competing for the same "hot" rows. It makes sense to view the queries running in the transaction and check if they're reading unnecessary rows.

What causes the "Exceeded maximum allowed number of active transactions" error?

The logic on the client side should try to keep transactions as short as possible.

No more than 10 active transactions are allowed per session. When starting a transaction, use either the commit flag for autocommit or an explicit commit/rollback.

What do I do if I get the Datashard: Reply size limit exceeded error in response to a query?

This error means that, as a query was running, one of the participating data shards attempted to return over 50 MB of data, which exceeds the allowed limit.

Recommendations:

- A general recommendation is to reduce the amount of data processed in a transaction.
- If a query involves a `Join`, it's a good idea to make sure that the method used is Index lookup Join.
- If a simple selection is performed, make sure that it is done by keys, or add `LIMIT` in the query.

What do I do is I get the "Datashard program size limit exceeded" in response to a query?

This error means that the size of a program (including parameter values) exceeded the 50-MB limit for one of the data shards. In most cases, this indicates an attempt to write over 50 MB of data to database tables in a single transaction. All modifying operations in a transaction such as `UPSERT`, `REPLACE`, `INSERT`, or `UPDATE` count as records.

You need to reduce the total size of records in one transaction. Normally, we don't recommend combining queries that logically don't require transactionality in a single transaction. When adding/updating data in batches, we recommend reducing the size of one batch to values not exceeding a few megabytes.

YQL

General questions

How do I select table rows by a list of keys?

You can select table rows based on a specified list of table primary key (or key prefix) values using the `IN` operator:

```
DECLARE $keys AS List<UInt64>;

SELECT * FROM some_table
WHERE Key1 IN $keys;
```

If a selection is made using a composite key, the query parameter must have the type of a list of tuples:

```
DECLARE $keys AS List<Tuple<UInt64, String>>;

SELECT * FROM some_table
WHERE (Key1, Key2) IN $keys;
```

To select rows effectively, make sure that the value types in the parameters match the key column types in the table.

Is search by index performed for conditions containing the LIKE operator?

You can only use the `LIKE` operator to search a table index if it specifies a row prefix:

```
SELECT * FROM string_key_table
WHERE Key LIKE "some_prefix%";
```

Why does a query return only 1000 rows?

1000 rows is the response size limit per YQL query. If a response is shortened, it is flagged as `Truncated`. To output more table rows, you can use paginated output or the `ReadTable` operation.

How to escape quotes of JSON strings when adding them to a table?

Consider an example with two possible options for adding a JSON string to a table:

```
UPSERT INTO test_json(id, json_string)
VALUES
    (1, Json(@@[{"name":"Peter \"strong cat\" Kourbatov"}]@@)),
    (2, Json('[{"name":"Peter \\\"strong cat\\\" Kourbatov"}]'))
;
```

To insert a value in the first line, use `raw string` and the escape method using `\"`. To insert the second line, escaping through `\\\"` is used.

We recommend using `raw string` and the escape method using `\"`, as it is more visual.

How do I update a JSON value in a table?

Partial updates of a JSON field are not supported, so it is necessary to construct a new value from parts of the old and new data. This is done using the `Yson` UDF combined with dictionary functions.

The example below adds a new field `new_field` to the JSON object stored in the `column` column:

```
UPDATE table
SET column = Yson::SerializeJson(
    Yson::From(
        SetUnion(
            Yson::ConvertTo(Yson::ParseJson(column), Dict<String, Yson>),
            {'new_field': Yson('"value"')},
            ($K, $v1, $v2) -> { RETURN COALESCE($v2, $v1); }
        )
    )
)
WHERE id = 1;
```

How do I update only those values whose keys are not in the table?

You can use the `LEFT JOIN` operator to identify the keys a table is missing and update their values:

```
DECLARE $values AS List<Struct<Key: UInt64, Value: String>>;

UPSERT INTO kv_table
SELECT v.Key AS Key, v.Value AS Value
FROM AS_TABLE($values) AS v
LEFT JOIN kv_table AS t
ON v.Key = t.Key
WHERE t.Key IS NULL;
```

Join operations

Are there any specific features of Join operations?

A `Join` in YDB is performed using one of the two methods below:

- Common Join.
- Index Lookup Join.

Common Join

The contents of both tables (to the left and to the right of `Join`) are sent to the requesting node which applies the operation to the totality of the data. This is the most generic way of performing a `Join` that is used whenever other optimizations are unavailable. For large tables, this method is either slow or doesn't work in general due to exceeding the data transfer limits.

Index Lookup Join

For rows on the left of `Join`, relevant values are looked up to the right. You use this method whenever the right part is a table and the `Join` key is its primary or secondary index key prefix. In this method, limited selections are made from the right table instead of full reads. This lets you use it when working with large tables.

> **Note**
>
> For most OLTP queries, we recommend using Index Lookup Join with a small size of the left part. These operations read little data and can be performed efficiently.

How do I Join data from query parameters?

You can use query parameter data as a constant table. To do this, use the `AS_TABLE` modifier with a parameter whose type is a list of structures:

```
DECLARE $data AS List<Struct<Key1: UInt64, Key2: String>>;

SELECT * FROM AS_TABLE($data) AS d
INNER JOIN some_table AS t
ON t.Key1 = d.Key1 AND t.Key2 = d.Key2;
```

There is no explicit limit on the number of entries in the constant table, but mind the standard limit on the total size of query parameters (50 MB).

What's the best way to implement a query like (key1, key2) IN ((v1, v2), (v3, v4), ...)?

You can use the `WHERE ... IN` syntax to query by a set of keys (including composite keys):

```
DECLARE $key_pairs AS List<Tuple<Uint64, Uint64>>;

SELECT * FROM some_table
WHERE (Key1, Key2) IN $key_pairs;
```

Transactions

How efficient is it to run multiple queries in a transaction?

When multiple queries are run sequentially, the total transaction latency may be greater than when the same operations are executed within a single query. This is primarily due to additional network latency for each query. Therefore, if a transaction doesn't need to be interactive, we recommend formulating all operations in a single YQL query.

Is a separate query atomic?

In general, YQL queries can be executed in multiple consecutive phases. For example, a Join query can be executed in two phases: reading data from the left and right table, respectively. This aspect is important when you run a query in a transaction with a low isolation level (`online_read_only`), as in this case, data between execution phases can be updated by other transactions.

Questions and answers about analytics in YDB

Can YDB be used for analytical workloads (OLAP)?

Yes, it can. If this is the primary type of workload for a given table, make sure it is column-oriented.

How to choose between row-oriented and column-oriented tables?

Similarly to choosing between transactional (OLTP) and analytical (OLAP) database management systems, this question comes to a number of trade-offs that need to be considered:

- **What's the main use case for the table?** For mostly transactional (OLTP) workloads, use row-oriented tables. For analytical workloads (OLAP), use column-oriented tables. Transactional workloads are characterized by a high rate of queries affecting a small number of rows each. Analytical workloads are characterized by processing large volumes of data to produce relatively small query results.
- **How is the table modified?** As a rule of thumb, row-oriented tables work better when data is frequently modified in place, while column-oriented tables work better when data is mostly appended by adding new rows. Thus, row-oriented tables usually reflect the current state of a dataset, while column-oriented tables often store a history of some sort of immutable events.
- **Which features are needed?** Even though YDB strives for feature parity between row-oriented and column-oriented tables, there might be current limitations to consider. Check the documentation for details on specific features intended to be used with a given table.

Unlike most other database management systems, YDB supports both row-oriented and column-oriented tables in the same database. However, keep in mind that transactional and analytical workloads have different resource consumption patterns and might affect each other when the cluster is overloaded.

Known issues

Table partitions are not merging when autopartitioning is enabled

For tables created in earlier versions of YDB, the autopartitioning mechanism does not merge partitions even when merge conditions based on load or size are met. This can result in an excessive number of partitions in the table.

This issue is specific to tables that meet the following two criteria:

- The table was created on a YDB cluster prior to version 22.2.
- The table had no minimum partition count value set, either at creation time or afterwards.

To resolve the issue, explicitly set a minimum partition count value for the table. For example, use the AUTO_PARTITIONING_MIN_PARTITIONS_COUNT parameter:

```
ALTER TABLE `my_table` SET (AUTO_PARTITIONING_MIN_PARTITIONS_COUNT = 1);
```

Errors

Possible causes for "Status: OVERLOADED Error: Pending previous query completion" in the C++ SDK

Q: When running two queries, I try to get a response from the future method of the second one. It returns: `Status: OVERLOADED Why: <main>: Error: Pending previous query completion`.

A: Sessions in the SDK are single-threaded. To run multiple queries at once, you need to create multiple sessions.

What do I do if I frequently get the "Transaction locks invalidated" error?

Typically, if you get this error, repeat a transaction, as YDB uses optimistic locking. If this error occurs frequently, this is the result of a transaction reading a large number of rows or of many transactions competing for the same "hot" rows. It makes sense to view the queries running in the transaction and check if they're reading unnecessary rows.

What causes the "Exceeded maximum allowed number of active transactions" error?

The logic on the client side should try to keep transactions as short as possible.

No more than 10 active transactions are allowed per session. When starting a transaction, use either the commit flag for autocommit or an explicit commit/rollback.

What do I do if I get the Datashard: Reply size limit exceeded error in response to a query?

This error means that, as a query was running, one of the participating data shards attempted to return over 50 MB of data, which exceeds the allowed limit.

Recommendations:

- A general recommendation is to reduce the amount of data processed in a transaction.
- If a query involves a `Join`, it's a good idea to make sure that the method used is Index lookup Join.
- If a simple selection is performed, make sure that it is done by keys, or add `LIMIT` in the query.

What do I do is I get the "Datashard program size limit exceeded" in response to a query?

This error means that the size of a program (including parameter values) exceeded the 50-MB limit for one of the data shards. In most cases, this indicates an attempt to write over 50 MB of data to database tables in a single transaction. All modifying operations in a transaction such as `UPSERT`, `REPLACE`, `INSERT`, or `UPDATE` count as records.

You need to reduce the total size of records in one transaction. Normally, we don't recommend combining queries that logically don't require transactionality in a single transaction. When adding/updating data in batches, we recommend reducing the size of one batch to values not exceeding a few megabytes.

YQL

General questions

How do I select table rows by a list of keys?

You can select table rows based on a specified list of table primary key (or key prefix) values using the `IN` operator:

```
DECLARE $keys AS List<UInt64>;

SELECT * FROM some_table
WHERE Key1 IN $keys;
```

If a selection is made using a composite key, the query parameter must have the type of a list of tuples:

```
DECLARE $keys AS List<Tuple<UInt64, String>>;

SELECT * FROM some_table
WHERE (Key1, Key2) IN $keys;
```

To select rows effectively, make sure that the value types in the parameters match the key column types in the table.

Is search by index performed for conditions containing the LIKE operator?

You can only use the `LIKE` operator to search a table index if it specifies a row prefix:

```
SELECT * FROM string_key_table
WHERE Key LIKE "some_prefix%";
```

Why does a query return only 1000 rows?

1000 rows is the response size limit per YQL query. If a response is shortened, it is flagged as `Truncated`. To output more table rows, you can use paginated output or the `ReadTable` operation.

How to escape quotes of JSON strings when adding them to a table?

Consider an example with two possible options for adding a JSON string to a table:

```
UPSERT INTO test_json(id, json_string)
VALUES
    (1, Json(@@[{"name":"Peter \"strong cat\" Kourbatov"}]@@)),
    (2, Json('[{"name":"Peter \\\"strong cat\\\" Kourbatov"}]'))
;
```

To insert a value in the first line, use `raw string` and the escape method using `\"`. To insert the second line, escaping through `\\\"` is used.

We recommend using `raw string` and the escape method using `\"`, as it is more visual.

How do I update a JSON value in a table?

Partial updates of a JSON field are not supported, so it is necessary to construct a new value from parts of the old and new data. This is done using the `Yson` UDF combined with dictionary functions.

The example below adds a new field `new_field` to the JSON object stored in the `column` column:

```
UPDATE table
SET column = Yson::SerializeJson(
    Yson::From(
        SetUnion(
            Yson::ConvertTo(Yson::ParseJson(column), Dict<String, Yson>),
            {'new_field': Yson('"value"')},
            ($K, $v1, $v2) -> { RETURN COALESCE($v2, $v1); }
        )
    )
)
WHERE id = 1;
```

How do I update only those values whose keys are not in the table?

You can use the `LEFT JOIN` operator to identify the keys a table is missing and update their values:

```
DECLARE $values AS List<Struct<Key: UInt64, Value: String>>;

UPSERT INTO kv_table
SELECT v.Key AS Key, v.Value AS Value
FROM AS_TABLE($values) AS v
LEFT JOIN kv_table AS t
ON v.Key = t.Key
WHERE t.Key IS NULL;
```

Join operations

Are there any specific features of Join operations?

A `Join` in YDB is performed using one of the two methods below:

- Common Join.
- Index Lookup Join.

Common Join

The contents of both tables (to the left and to the right of `Join`) are sent to the requesting node which applies the operation to the totality of the data. This is the most generic way of performing a `Join` that is used whenever other optimizations are unavailable. For large tables, this method is either slow or doesn't work in general due to exceeding the data transfer limits.

Index Lookup Join

For rows on the left of `Join`, relevant values are looked up to the right. You use this method whenever the right part is a table and the `Join` key is its primary or secondary index key prefix. In this method, limited selections are made from the right table instead of full reads. This lets you use it when working with large tables.

> **Note**
>
> For most OLTP queries, we recommend using Index Lookup Join with a small size of the left part. These operations read little data and can be performed efficiently.

How do I Join data from query parameters?

You can use query parameter data as a constant table. To do this, use the `AS_TABLE` modifier with a parameter whose type is a list of structures:

```
DECLARE $data AS List<Struct<Key1: UInt64, Key2: String>>;

SELECT * FROM AS_TABLE($data) AS d
INNER JOIN some_table AS t
ON t.Key1 = d.Key1 AND t.Key2 = d.Key2;
```

There is no explicit limit on the number of entries in the constant table, but mind the standard limit on the total size of query parameters (50 MB).

What's the best way to implement a query like (key1, key2) IN ((v1, v2), (v3, v4), ...)?

You can use the `WHERE ... IN` syntax to query by a set of keys (including composite keys):

```
DECLARE $key_pairs AS List<Tuple<Uint64, Uint64>>;

SELECT * FROM some_table
WHERE (Key1, Key2) IN $key_pairs;
```

Transactions

How efficient is it to run multiple queries in a transaction?

When multiple queries are run sequentially, the total transaction latency may be greater than when the same operations are executed within a single query. This is primarily due to additional network latency for each query. Therefore, if a transaction doesn't need to be interactive, we recommend formulating all operations in a single YQL query.

Is a separate query atomic?

In general, YQL queries can be executed in multiple consecutive phases. For example, a Join query can be executed in two phases: reading data from the left and right table, respectively. This aspect is important when you run a query in a transaction with a low isolation level (`online_read_only`), as in this case, data between execution phases can be updated by other transactions.

Analytics

Can YDB be used for analytical workloads (OLAP)?

Yes, it can. If this is the primary type of workload for a given table, make sure it is column-oriented.

How to choose between row-oriented and column-oriented tables?

Similarly to choosing between transactional (OLTP) and analytical (OLAP) database management systems, this question comes to a number of trade-offs that need to be considered:

- **What's the main use case for the table?** For mostly transactional (OLTP) workloads, use row-oriented tables. For analytical workloads (OLAP), use column-oriented tables. Transactional workloads are characterized by a high rate of queries affecting a small number of rows each. Analytical workloads are characterized by processing large volumes of data to produce relatively small query results.
- **How is the table modified?** As a rule of thumb, row-oriented tables work better when data is frequently modified in place, while column-oriented tables work better when data is mostly appended by adding new rows. Thus, row-oriented tables usually reflect the current state of a dataset, while column-oriented tables often store a history of some sort of immutable events.
- **Which features are needed?** Even though YDB strives for feature parity between row-oriented and column-oriented tables, there might be current limitations to consider. Check the documentation for details on specific features intended to be used with a given table.

Unlike most other database management systems, YDB supports both row-oriented and column-oriented tables in the same database. However, keep in mind that transactional and analytical workloads have different resource consumption patterns and might affect each other when the cluster is overloaded.

Known issues

Table partitions are not merging when autopartitioning is enabled

For tables created in earlier versions of YDB, the autopartitioning mechanism does not merge partitions even when merge conditions based on load or size are met. This can result in an excessive number of partitions in the table.

This issue is specific to tables that meet the following two criteria:

- The table was created on a YDB cluster prior to version 22.2.
- The table had no minimum partition count value set, either at creation time or afterwards.

To resolve the issue, explicitly set a minimum partition count value for the table. For example, use the AUTO_PARTITIONING_MIN_PARTITIONS_COUNT parameter:

```
ALTER TABLE `my_table` SET (AUTO_PARTITIONING_MIN_PARTITIONS_COUNT = 1);
```

SDK

What should I do if the SDK crashes when shutting down an application?

Make sure not to wrap SDK components in a singleton, since their lifetime shouldn't exceed the execution time of the `main()` function. When a client is destroyed, session pools are emptied, so network navigation is required. But gRPC contains global static variables that might already be destroyed by this time. This disables gRPC. If you need to declare a driver as a global object, invoke the `Stop(true)` function on the driver before exiting the `main()` function.

What should I do if, when using a `fork()` system call, a program does not work properly in a child process?

Using `fork()` in multithreaded applications is an antipattern. Since both the SDK and the gRPC library are multithreaded applications, their stability is not guaranteed.

What do I do if I get the "Active sessions limit exceeded" error even though the current number of active sessions is within limits?

The limit applies to the number of active sessions. An active session is a session passed to the client to be used in its code. A session is returned to the pool in a destructor. In this case, the session itself is a replicated object. You may have saved a copy of the session in the code.

Is it possible to make queries to different databases from the same application?

Yes, the C++ SDK lets you override the DB parameters and token when creating a client. There is no need to create separate drivers.

What should I do if a VM has failed and it's impossible to make a query?

To detect that a VM is unavailable, set a client timeout. All queries contain the client timeout parameters. The timeout value should be an order of magnitude greater than the expected query execution time.

Videos

This section contains video recordings from conferences and webinars:

- Videos 2025
- Videos 2024
- Videos 2023
- Videos 2022

The materials are divided by categories and tagged:

Overview	– overview materials that introduce YDB and the technologies used in it.
Use cases	– use cases of YDB.
Practice	– best practices for using YDB.
Database internals	– a detailed analysis of the internal implementation of YDB or its individual parts and mechanisms.
Releases	– an overview of new features and released versions of YDB.
Testing	– performance testing cases of YDB and comparisons with other similar-class DBMSs.
General	– generic materials.

Videos 2025

Implementing an MCP Server for DBMS in Python — YDB's Experience

Database internals

Discover how YDB leverages the Model Context Protocol (MCP) to bridge AI models with database systems. Ivan Blinkov (VP, Product and Open Source) shares the story of the development of a Python-based MCP server that enables seamless interactions between large language models and YDB's open-source Distributed DBMS. Learn about the design decisions, challenges faced, and the practical benefits of integrating MCP into data architecture. Ideal for developers and AI practitioners aiming to enhance AI capabilities with direct database access.

The presentation will be of interest to developers who want to integrate their products with AI via the MCP protocol.

Slides

Designing YDB: Constructing a Distributed cloud-native DBMS for OLTP and OLAP from the Ground Up

Database internals

Distributed systems offer multiple advantages: they are built to be fault-tolerant and reliable, can scale almost infinitely, provide low latency in geo-distributed scenarios, and, finally, are geeky and fun to explore. YDB is an open-source distributed SQL database that has been running in production for years. Some installations include thousands of servers storing petabytes of data. To provide these capabilities, any distributed DBMS must achieve consistency and consensus while tolerating unreliable networks, faulty hardware, and the absence of a global clock.

In this session, we will provide a gentle introduction to the problems, challenges, and fallacies of distributed computing, explaining why sharded systems like Citus are not always ACID-compliant and how they differ from truly distributed systems. Then, we will dive deep into the design decisions made by YDB to address these difficulties and outline YDB's architecture layer by layer: from bare metal disks and distributed storage to OLTP and OLAP functionalities. Finally, we will briefly compare our approach with that of Calvin, which originally inspired YDB, and Spanner.

Evgenii Ivanov (Senior developer) discussed the architecture of YDB, focusing on building a unified platform for fault-tolerant and reliable OLTP and OLAP processing.

The presentation will be of interest to developers of high-load systems and platform developers for various purposes.

Slides

Designing YDB: Constructing a Distributed cloud-native DBMS for OLTP and OLAP from the Ground Up

Database internals

Distributed systems are great in multiple aspects: they are built to be fault-tolerant and reliable, can scale almost infinitely, provide low latency in geo-distributed scenarios, and, finally, they are geeky and fun to explore. YDB is a distributed SQL database that has been running in production for years. There are installations with thousands of servers storing petabytes of data. To provide these capabilities, any distributed DBMS must achieve consistency and consensus while tolerating unreliable networks, faulty hardware, and the absence of a global clock.

In this session, we will briefly introduce the problems, challenges, and fallacies of distributed computing, explaining why sharded systems like Citus are not always ACID and differ from truly distributed systems. Then, we will dive deep into the design decisions made by YDB to address these difficulties and outline YDB's architecture layer by layer, from the bare metal disks and distributed storage up to OLTP and OLAP functionalities. Ultimately, we will briefly compare our approach with Calvin's, which initially inspired YDB, and Spanner.

Evgenii Ivanov (Senior developer) discussed the architecture of YDB, focusing on building a unified platform for fault-tolerant and reliable OLTP and OLAP processing.

The presentation will be of interest to developers of high-load systems and platform developers for various purposes.

YDB: How to implement streaming RAG in a distributed database

Database internals

Extracting real-time insights from multi-modal data streams across diverse domains presents an ongoing challenge. A promising solution lies in the implementation of Streaming Retrieval-Augmented Generation (RAG) techniques. YDB enhances this approach by offering robust services for both vector search and streaming, facilitating more efficient and effective data processing and retrieval. YDB is a versatile open-source Distributed SQL Database that combines high availability and scalability with strong consistency and ACID transactions.

Alexander Zevaykin (Team leader) and Elena Kalinina (Technical Project Manager) discussed an approach to implementing streaming RAG in YDB.

The presentation will be of interest to developers of high-load systems and platform developers for various purposes.

Slides

Sharded and Distributed Are Not the Same: What You Must Know When PostgreSQL Is Not Enough

Testing

It's no secret that PostgreSQL is extremely efficient and scales vertically well. At the same time, it isn't a secret that PostgreSQL scales only vertically, meaning its performance is limited by the capabilities of a single server. Most Citus-like solutions allow the database to be sharded, but a sharded database is not distributed and does not provide ACID guarantees for distributed transactions. The common opinion about distributed DBMSs is diametrically opposed: they are believed to scale well horizontally and have ACID distributed transactions but have lower efficiency in smaller installations.

When comparing monolithic and distributed DBMSs, discussions often focus on architecture but rarely provide specific performance metrics. This presentation, on the other hand, is entirely based on an empirical study of this issue. Our approach is simple: Evgenii Ivanov (Senior developer) installed PostgreSQL and distributed DBMSs on identical clusters of three physical servers and compared them using the popular TPC-C benchmark.

The presentation will be of interest to developers of high-load systems and platform developers for various purposes.

Videos 2024

Enhancing a Distributed SQL Database Engine: A Case Study on Performance Optimization

Database internals

Learn how we optimized a distributed SQL database engine, focusing on benchmark-driven improvements, and pivotal testing strategies. Alexey Ozeritskiy (Lead Software Engineer) will talk about performance optimization of distributed SQL engine. He will discuss background information about YDB engine itself and where it is used. The final part of his talk will be about containerization and performance.

The presentation is suitable for DBA.

Slides

YDB: extending a Distributed SQL DBMS with PostgreSQL compatibility

Database internals

PostgreSQL is an implementation of SQL standard with one of the most vibrant ecosystems around it. To leverage all the tools and libraries that already know how to work with PostgreSQL, emerging database management systems that bring something new to the market need to learn how to mimic PostgreSQL. In this talk at COSCUP 2024 Ivan Blinkov (VP, Product and Open Source) explores possible approaches to this and related trade-offs, as well as reasoning why YDB chose a unique approach to bring serializable consistency and seamless scalability to the PostgreSQL ecosystem.

> **Note**
>
> The video will be available later.

The presentation is suitable for people interested in trade-offs during implementation of PostgreSQL-compatible DBMS.

Slides

Breaking out of the cage: move complex development to GitHub

General

Alexander Smirnov (Technology Expert at Nebius) shows how the YDB team moved its primary development branch from an in-house repository to GitHub, set up independent commodity on-demand cloud infrastructure, CI processes with GitHub Actions, test management with open source and cloud tools. Special attention will be paid to the complexities of decoupling from the corporate monorepository and build system.

The presentation is suitable for DevOps engineers (CI/CD).

Slides

Introducing YDB, a Distributed SQL DBMS for mission-critical workloads

Overview

YDB is a versatile open-source Distributed SQL Database that combines high availability and scalability with strong consistency and ACID transactions. It accommodates transactional (OLTP), analytical (OLAP), and streaming workloads simultaneously. It is publicly available under Apache 2.0, one of the most permissive open-source licenses. In this talk at IndiaFOSS 2024, Ivan Blinkov (VP, Product and Open Source) introduces the system and explains how it can be used to build reliable data-driven applications that implement business-critical processes.

Slides

Working with Raw Disk Drives in Kubernetes — YDB's Experience | 在Kubernetes中使用原始磁盘驱动器——YDB的经验

Database internals

YDB is an open-source distributed database management system that, for performance reasons, uses raw disk drives (block devices) to store all data without any filesystem. It was relatively straightforward to manage such a setup in the bare-metal world of the past, but the dynamic nature of cloud-native environments introduced new challenges to keep this performance benefit. In this talk at KubeCon + CloudNativeCon + Open Source Summit Hong Kong, Ivan Blinkov (VP, Product and Open Source) explores how to leverage Kubernetes and the Operator design pattern to modernize how stateful distributed database clusters are managed without changing the primary approach to how the data is physically stored.

YDB是一个开源的分布式数据库管理系统，为了性能考虑，使用原始磁盘驱动器（块设备）存储所有数据，而不使用任何文件系统。在过去的裸金属世界中管理这样的设置相对比较简单，但云原生环境的动态特性引入了新的挑战，以保持这种性能优势。在这次演讲中，我们将探讨如何利用Kubernetes和运算符设计模式来现代化管理有状态的分布式数据库集群，而不改变数据物理存储的主要方法。

Slides

YDB: dealing with Big Data and moving towards AI

General

Alexander Zevaykin (Team leader) talks about YDB — a versatile, open-source Distributed SQL database management system that combines high availability and scalability with strong consistency and ACID transactions. It provides services for machine learning products and goes beyond traditional vector search capabilities.

> **Note**
>
> The video will be available later.

This database is used for industrial operations within Yandex. Among its clients are Yandex Market, Yandex Alice, and Yandex Taxi, which are some of the largest and most demanding AI-based applications.

The database offers true elastic scalability, capable of scaling up or down by several orders of magnitude.

Simultaneously, the database is fault-tolerant. It is designed to operate across three availability zones, ensuring continuous operation even if one of the zones becomes unavailable. The database automatically recovers from disk failures, server failures, or data center failures, with minimal latency disruptions to applications.

Currently, work is underway to implement accurate and approximate nearest neighbour search for machine learning purposes.

Takeaways:

- Architecture of a distributed, fault-tolerant database.
- Approaches to implementing vector search on large datasets.

Slides

An approach to unite tables and persistent queues in one system

General Database internals

People need databases to store their data and persistent queues to transfer their data from one system to another. We've united tables and persisted queues within one data platform. Now you have a possibility to take your data from a queue, then process it and keep the result in a database within a single transaction. So your application developers don't need to think about data inconsistency in cases of connection failures or other errors.

Elena Kalinina (Technical Project Manager) tell you about an open-source platform called YDB which allows you to work with tables and queues within a single transaction. Elena walk you through architecture decisions, possible scenarios, and performance aspects of this approach.

Slides

YDB vs. TPC-C: the Good, the Bad, and the Ugly behind High-Performance Benchmarking

Database internals

Modern distributed databases scale horizontally with great efficiency, making them almost limitless in capacity. This implies that benchmarks should be able to run on multiple machines and be very efficient to minimize the number of machines required. This talk will focus on benchmarking high-performance databases, particularly emphasizing YDB and our implementation of the TPC-C benchmark, the de facto gold standard in the database field.

First, we will speak about benchmarking strategies from a user's perspective. We will dive into key details related to benchmark implementations, which could be useful when you create a custom benchmark to mirror your production scenarios. Throughout our performance journey, we have identified numerous anti-patterns: there are things you should unequivocally avoid in your benchmark implementations. We'll highlight these "bad" and "ugly" practices with illustrative examples.

Next, we'll briefly discuss the popular key-value benchmark YCSB, which is a prerequisite for robust performance in distributed transactions. We'll then explore the TPC-C benchmark in greater detail, sharing valuable insights derived from our own implementation.

We'll conclude our talk by presenting performance results from the TPC-C benchmark, comparing YDB and CockroachDB with PostgreSQL to illustrate situations where PostgreSQL might not be enough and when you might want to consider a distributed DBMS instead.

Evgenii Ivanov (Senior developer) discussed best high-performance benchmarking practices and some pitfalls found during TPC-C implementation, then demonstrated TPC-C results of PostgreSQL, CockroachDB, and YDB.

The presentation will be of interest to developers of high-load systems and developers of platforms for various purposes.

YDB — an open-source distributed SQL database

Overview

YDB is used as a mission-critical database for many Internet-scale services. YDB has been designed as a platform for various data storage and processing systems and is aimed at solving a wide range of problems. Oleg Bondar (CPO YDB) spoke about the structure of YDB, its main features, and benefits.

The presentation is suitable for everyone who is not yet familiar with YDB.

Slides

Scale it easy: YDB's high performance in a nutshell

Database internals

Implementing a distributed database with strong consistency isn't difficult; ensuring speed and scalability is the challenge. YDB excels in these aspects. In this talk, we'll discuss YDB's architecture and high performance, present benchmark results, and compare YDB to top competitors.

Evgenii Ivanov (Senior developer) discussed the architecture of YDB, demonstrated its high performance through benchmark results, and compared YDB with its competitors.

The presentation will be of interest to developers of high-load systems and developers of platforms for various purposes.

YDB — a Distributed SQL Database

Overview

This is a recording of a guest lecture in Belgrade University at the faculty of Mathematics. In this video, Anton Kovalenko (Technical Project Manager) describes the reasons why distributed SQL databases were created. He illustrates a brief history of Distributed SQL DBMS development, which products have appeared first.

Slides

Videos 2022

Parallel asynchronous replication between YDB database instances

Database internals

In this talk, we present an approach to asynchronous replication in YDB that provides the following characteristics: changefeed from the source database is sharded among multiple persistent queues, sharded changefeed is applied to the target database in a manner that guarantees the target database consistency.

Slides

Scalability and Fault Tolerance in YDB

In this talk, we will cover two layers of YDB: Tablet and BlobStorage, which together provide fault tolerance, scalability, and user isolation.

Articles

This section contains articles about YDB:

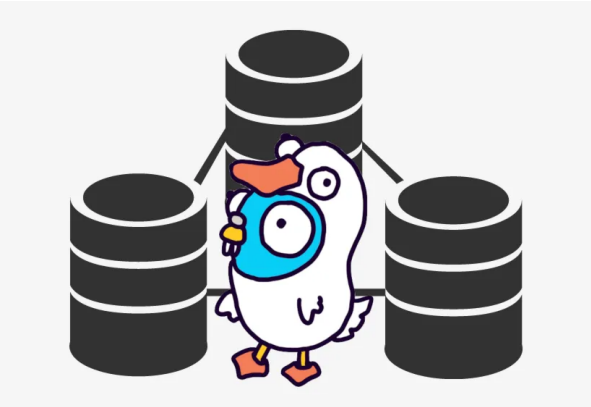
When Postgres is not enough: performance evaluation of PostgreSQL vs. Distributed DBMSs

Database internals

The research presented is the result of our joint effort and close collaboration with Evgeny Efimkin, an expert in PostgreSQL who doesn't work on YDB.

How we switched to Java 21 virtual threads and got a deadlock in TPC-C for PostgreSQL

Database internals



In this post, we present a case study on how we encountered a deadlock with virtual threads in TPC-C for PostgreSQL, even without the dining philosophers problem. This post might be helpful for Java developers who are considering switching to virtual threads.

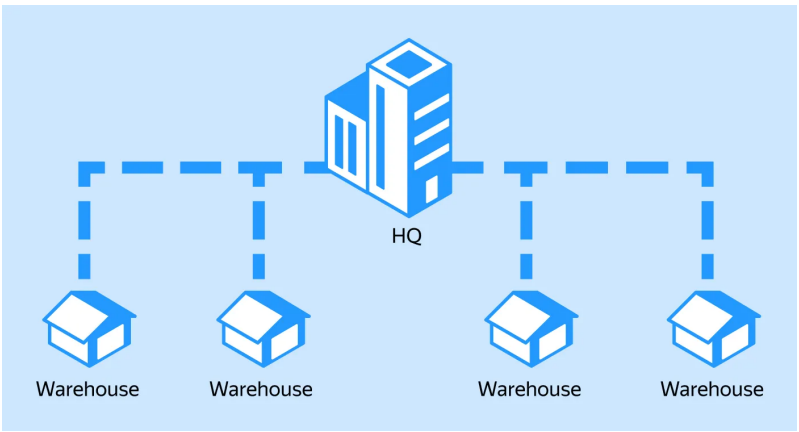
Articles 2023

Migrations in YDB using “goose”

Database internals

Any production process that works with a database will require a schema migration sooner or later. The migration updates the database’s table structure from one version to the next. Schema migrations can be done manually by executing an `ALTER TABLE` query or by using specialized tools. One such tool is called goose. In this article we see how goose provides schema management in a project and has supported YDB (a distributed open-source database) since v3.16.0.

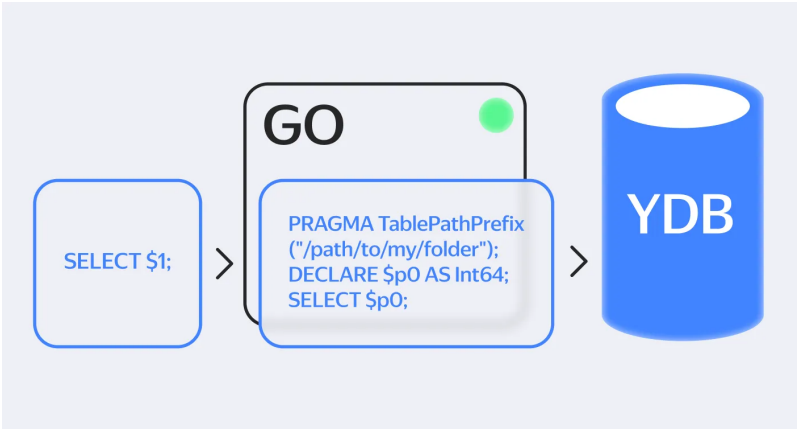
About prepared statements, server-side compiled query cache, or how to efficiently cache queries in YDB



Database internals

There are various ways to reduce the cost of SQL query execution in modern DBMS. The most common approaches are using prepared statements and query caching. Both methods are available in YDB. Their functionality and benefits are discussed in this article.

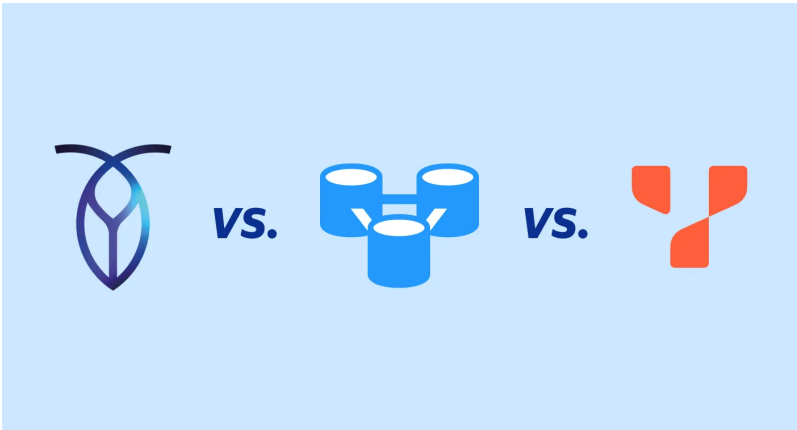
YDB meets TPC-C: distributed transactions performance now revealed



Database internals

We are excited to present our first results of TPC-C*, which is industry-standard On-Line Transaction Processing (OLTP) benchmark. According to these results, there are scenarios in which YDB slightly outperforms CockroachDB, another trusted and well-known distributed SQL database.

database/sql bindings for YDB in Go



Database internals

YQL is a SQL dialect with YDB specific strict types. This is great for performance and correctness, but sometimes can be a bit daunting to express in a query, especially when they need to be parametrized externally from the application side. For instance, when a YDB query needs to be parametrized, each parameter has name and type provided via `DECLARE` statement. To explore more about this and see practical examples, read the detailed explanation in this article.

YCSB performance series: YDB, CockroachDB, and YugabyteDB

Database internals

It's a challenge to implement a distributed database with strong consistency, ensuring high speed and scalability. YDB excels in these aspects, and our customers can attest to this through their own experiences. Unfortunately, we have never presented any performance numbers to a broader audience. We recognize the value of this information, and we are preparing more benchmark results to share.

YDB Downloads

This section provides instructions for downloading various YDB builds and related tools:

- YDB server (`ydbd`):
  - YDB Open-Source Database
  - Yandex Enterprise Database
- Command-line client utility (`ydb`)
- Disk substem management utility (`ydb-dstool`)
- Cluster management utility (`ydbops`)
- Ansible playbooks

Download YDB Open-Source Database

YDB Open-Source Database (`ydbd`) is an executable file for running a node in the YDB cluster. It is distributed under the Apache 2.0 license.

See also Download Yandex Enterprise Database.

Download Yandex Enterprise Database

Yandex Enterprise Database is a commercial database management system based on the YDB core.

Yandex Enterprise Database Usage Terms

Yandex Enterprise Database is distributed under the terms of the license agreement.

Free Usage

Yandex Enterprise Database (Product) can be used free of charge under the terms of the license agreement for the following purposes:

- To evaluate and study the Product's features
- As part of software development and testing processes that use or embed Product functions
- For training in Product administration
- For learning the specifics of developing software that interacts with the Product

Commercial Usage

For commercial use of Yandex Enterprise Database, a license purchase is required, license agreement text. License prices are available upon request.

Downloading Distributions

Yandex Enterprise Database distributions are available for download via the links below.

Linux

YDB Enterprise Server (`ydbd`) is an executable file for running a Yandex Enterprise Database node.

Certified version

Certified versions of Yandex Enterprise Database are not available for public download. Access is provided upon request.

The certified version of Yandex Enterprise Database 25.1 has a technical support end date of 30 October 2030.

Download YDB CLI

YDB CLI (`ydb`) is a command-line utility for working with YDB databases. It is distributed under the Apache 2.0 license.

> **Tip**
>
> The recommended way to install YDB CLI is by using the installation script. The script automatically downloads the appropriate binary and adds it to your `PATH` .

Linux (amd64)

YDB Server changelog

Version 26.3

Release candidate 26.3.1.16

Release date: 18.09.26

Functionality

- Backup export and import are available for column-oriented tables, including S3-compatible storage.
- Column-oriented table columns support dictionary encoding. Use `ENCODING(DICT)` for low-cardinality values.
- Local min_max indexes are enabled for column-oriented tables. They skip data fragments outside a query range, reducing the amount of data read.
- Added storage group decommissioning through virtual storage groups. Data moves to virtual groups in the background while applications continue reading and writing data.
- Added authentication through external OpenID Connect identity providers. YDB validates JWT tokens using the provider's JSON Web Key Set (JWKS) and periodically refreshes authentication data.
- Kafka API supports mutual TLS authentication. A client certificate is mapped to a security identifier and SASL authentication is not required.
- Columnar engine optimization: column-oriented tables use an updated compaction strategy that organizes data more efficiently.
- Authentication and authorization subsystem optimization: bulk authorization requests to AccessService are enabled by default, reducing authorization request overhead.
- Streaming YQL queries can access system virtual attributes such as `__ydb_create_time`, `__ydb_write_time`, and others, as well as user attributes `__ydb_user_attributes`. Feature documentation.
- Distributed Storage optimization: full VDisk synchronization is faster because processed SyncLog data is removed locally by default.
- Added transfer metrics and statistics to `DescribeTransfer` for monitoring and diagnostics.
- Added a configurable limit for stored forced-compaction operations. Completed and cancelled operations can be removed automatically when the limit is reached.
- Change Data Capture records can include the OpenTelemetry trace ID of the request that produced the change.
- Topic reads that start from a timestamp filter out messages with earlier write timestamps, including messages stored in the same blob as newer messages.

Disabled functionality

The following functionality is not enabled by default.

- For column-oriented tables, `ALTER TABLE ... COMPACT` can start forced compaction.
- Column-oriented and row-oriented tables now have parity in the set of YQL data types (`Interval`, `Uuid`, and `DyNumber` are supported).
- Added hybrid search, combining full-text relevance and vector similarity into one ranked result.
- Topics can be accessed through the Amazon SQS API, allowing SQS-compatible clients to read and write messages.
- Added JSON indexes for accelerating `JSON_EXISTS` and `JSON_VALUE` queries.
- Full-text indexes support filter columns, allowing search within a logical table partition.
- Full-text indexes can be created for tables with arbitrary primary-key types.

Version 26.2

Version 26.2.1.14

Release date: September 16, 2026.

Functionality

- Full-text indexes are enabled by default.
- Streaming queries can read from local topics, write to local topics, read local tables, and contain multiple `INSERT` statements.
- Streaming queries support watermarks.
- Added Bloom skip indexes: Bloom and Bloom n-gram indexes for column-oriented tables, and prefix Bloom indexes for row-oriented tables.
- Column compression settings for column-oriented tables are available by default.
- The parallelism level can now be configured for index builds.
- For row-oriented tables, `ALTER TABLE` statements `ALTER COLUMN SET DEFAULT` and `ALTER COLUMN DROP DEFAULT` are available by default.
- For row-oriented tables, the YQL statement `TRUNCATE TABLE` is available by default.
- The YQL statement `DISCARD SELECT` is available by default.
- QueryService can return query results in Apache Arrow format; this capability is enabled by default.
- Added forced compaction for row-oriented tables using `ALTER TABLE ... COMPACT`.
- Added automatic storage balancing between groups and background validation of disk placement.
- Table split and merge operations are faster for tables with many partitions: SchemeShard updates only the affected partitions instead of rebuilding the entire partition list.
- Added audit logging for topic operations.
- Added built-in minidump collection based on Google Breakpad for Linux nodes.
- Added the `ydb-dstool pdisk populate` subcommand for reproducing a PDisk workload on another device.

Disabled functionality

This functionality is present in the core to allow rollback from the future 26.3 release, but is not enabled by default. It will be enabled by default in the next major release. It may also be enabled in some managed YDB services.

- Added support for incremental backups, which store only changes relative to the preceding backup in a collection.
- Column-oriented tables can be exported and imported using S3-compatible storage.
- Added export and import of row-oriented tables using a local file system, including file systems mounted over NFS.

- Added snapshot retention for long-running analytical queries over column-oriented tables, preventing snapshot data from being removed before a query completes.
- QueryService can notify SDKs when a node or session is shutting down, allowing clients to stop sending new queries there.
- Added database-level limits on the count and volume of small blobs for column-oriented tables. New writes are rejected when the hard limit is exceeded.
- Watermark expressions can be evaluated outside the context of an individual message.
- Added min-max skip indexes for column-oriented tables.
- Added dictionary encoding for columns in column-oriented tables.
- Added online construction of unique secondary indexes.
- Transactions between topics and tables can use optimized conflict checking.

Bug Fixes

- Fixed incorrect results from some scan queries over column-oriented tables.
- Fixed handling of malformed Kafka requests that could cause excessive memory use or out-of-bounds access.
- Fixed topic reads hanging after a read balancer restart.
- Fixed race conditions in the server-side topic read session and in the Topic SDK.
- Fixed a crash and a hang in streaming query checkpointing.
- Fixed race conditions when cancelling and planning distributed transactions.
- Fixed handling of oversized blocks during encrypted export and a false data corruption error during encrypted restore.
- Fixed a race condition when collecting statistics with `ydb workload topic`.
- Fixed a double free during `DqHashCombine` spilling teardown.
- Fixed lost `ReadSet` acknowledgements that could prevent a transaction involving topics from completing.
- Fixed handling of `NODATA` responses in the KeyValue API: `NOT_FOUND` or `INTERNAL_ERROR` is returned instead of terminating the process.
- Fixed IAM authentication for external data sources in Generic Provider and error handling for provider responses.
- Fixed a memory leak when loading external data source metadata.
- Fixed parsing of tri-state feature flags in YAML configuration that could cause subsequent settings to be lost.
- Fixed copying and exporting tables with secondary indexes after index implementation tables were removed.
- Fixed object filtering and list operations during file-system export.
- Fixed Kafka API Metadata responses that could return an empty broker list or an inconsistent controller ID, causing Kafka AdminClient and Kafka Streams operations to time out.
- Fixed a leak of script execution records created by streaming queries.
- Fixed `local-ydb` overwriting a user-provided `config.yaml` mounted at the default path during the first Docker deployment.
- Fixed a Hive crash on restart when a tablet lock and its persisted leader pointed to different nodes.

Version 26.1

Version 26.1.1.22

Release date: July 27, 2026.

Bug Fixes

- Fixed Kafka API authentication for local users: with enabled `DomainLoginOnly` setting, users could not access tenant databases.
- Fixed a crash (use-after-free) when updating a vector index caused by asynchronous ReadActor destruction.

Version 26.1.1.20

Release date: July 2, 2026.

Functionality

- YQL statements `SHOW CREATE TABLE` and `SHOW CREATE VIEW` return the DDL required to recreate a table or view.
- `ALTER TABLE` supports default values in `ADD COLUMN` (`DEFAULT`).
- Shuffle Elimination is enabled in production: the optimizer can remove unnecessary data shuffles in joins.
- Backup and restore now cover asynchronous replications, external data sources, external tables, and transfers.
- The cluster keeps running when CMS is unavailable.
- Dynamic nodes can be registered using client TLS certificates.
- LDAP service account authentication supports the SASL EXTERNAL mechanism — see `enable_sasl_external_bind`.
- Asynchronous replication mirroring supports auto-partitioned topics; see also topic partitions in CDC.
- TLI (Transaction Lock Invalidation) diagnostics were extended: `tli_config`, logging, and system views.
- Load-based auto-partitioning considers CPU load on the partition leader and all its replicas.
- Streaming queries support writing results to local tables.
- Changefeeds (CDC) can export user security identifiers (`USER_SIDS`) — see `ALTER TABLE` `CHANGEFEED`.
- External data sources support `AUTH_METHOD=IAM`.
- CLI supports token file authentication (`--token-file`).
- Transaction handling between topics and tables has been optimized.

Bug Fixes

- Fixed `RETURNING` in streaming `UPDATE` and interactive queries.
- Fixed `SET DEFAULT` and `DROP DEFAULT` in `ALTER TABLE`.
- Fixed auth token expiry handling in the ticket parser.
- Fixed query execution in Workload Manager after tenant recreation.
- Fixed a use-after-free in the gRPC service layer.
- Fixed incremental restore surviving SchemeShard restarts and shard failures.
- Fixed streaming query metadata missing immediately after creation.
- Fixed async checkpointing stalling when input is full and the checkpoint is empty.

- Fixed cross-database quota interference in the Kesus quoter proxy.
- Fixed hangs in PQ read sessions.
- Fixed scan executor hangs on `SELECT … LIMIT` over empty tables.
- Fixed TLI deferred `LOCKS_BROKEN` flush accounting.
- Fixed streaming query timeout overflow.
- Fixed thread safety and token expiry parsing in the IAM credentials provider.
- Fixed errors in the HTTP gateway.
- Fixed integer overflow when handling null passwords.
- Fixed CDC collection disabled for `IsBuildInProgress` columns.
- Fixed segfault during updates.
- Fixed Shuffle Elimination with the `HashJoinMode` pragma.
- Fixed duplicated rows in scan queries after delivery issues.
- Fixed viewer HTTP endpoints restricted to viewer/admin SIDs; database scope enforced for database-only tokens.
- Fixed OOM when loading trash on blob depot.
- Fixed `TQueryBase` crash after cancelling a streaming query.
- Fixed local CDC reads from YQL.
- Fixed quick remote cancellation in the query service.

Version 25.4

Version 25.4.1.15

Release date: June 5, 2026.

Functionality

- YQL statements `BATCH UPDATE` and `BATCH DELETE FROM` are available for bulk updates and deletes in tables.
- The write execution path has changed substantially: writes now run in streaming mode without fully materializing data on the Query Processor side before sending it to DataShards, which improves performance for large write workloads. The change applies to a subset of scenarios; in some cases (for example, tables with secondary indexes) the previous approach is still used. For an overview of the execution pipeline, see Query execution.
- Lookup Join execution was optimized: it uses a streaming mode without materializing one side of the join, which lowers peak memory use, speeds up queries over large datasets, and removes previous limits on join side sizes. See Index lookup Join and the `JOIN` operator syntax.
- You can now configure access permissions for cluster and database system views.
- Row-oriented tables support configurable cache modes, including a new `in_memory` mode that preloads table data into RAM when sufficient memory is available.
- Topic consumers gained an `availability-period` parameter that extends retention of uncommitted messages beyond `retention-period`.
- Per-partition topic metrics and export to user shard quotas are available for accounting and observability.
- Faster queries with `LIMIT` on column-oriented tables through early result limiting on storage nodes (for queries with no sort or with sort by primary key). See `LIMIT` and `OFFSET` in YQL.
- Column-oriented tables support the `Bool` type in schema and queries — see primitive YQL types.
- A filtered vector index correctly returns rows inserted after the index was created when filter column values are new.
- Stream processing and data delivery are more tightly integrated into the core: topic → table transfer; streaming queries are available to users when `EnableStreamingQueries` is enabled.
- The `overlap_clusters` option substantially improves vector search quality by placing vectors in multiple index clusters (index settings) — see Vector indexes.
- Vector index search is significantly faster across all index types because distances are computed locally on each DataShard before data is sent over the network — see VIEW (vector index) and Vector indexes.
- Full vector search without an ANN index is faster thanks to pushdown (vector search, KNN UDF) — see Vector search and the KNN module.
- Database-stored secrets are fully supported (create, alter, drop, and use) — see Secrets. Note that the legacy syntax is deprecated.
- `UNION ALL` execution was improved with parallel execution, improving performance of analytical queries.

Bug Fixes

- Fixed an LDAP authentication vulnerability: knowing the login and password of any LDAP user (including one who is not a member of a group allowed to access YDB), an attacker could bypass group membership checks and gain access to the cluster (LDAP search filter injection; special characters are now escaped per RFC 2254).

Version 25.3

Version 25.3.1.27

Release date: May 20, 2026.

Functionality

- Added support for two–data center configuration with synchronous data writes (Bridge mode). Available in YDB Enterprise.
- Topic improvements:
  - In Kafka API compacted topics can now be created, and YDB automatically creates and removes the internal service consumer used for topic compaction;
  - Topic APIs were extended with new `DescribeConsumer` and per-partition topic metrics can now be exported into user quotas.
- Implemented backup and restore of topic configuration to and from S3;
- Implemented backup and restore (`VIEW`) to S3 and from S3.

Bug Fixes

- Fixed an LDAP authentication vulnerability: knowing the login and password of any LDAP user (including one who is not a member of a group allowed to access YDB), an attacker could bypass group membership checks and gain access to the cluster

(LDAP search filter injection; special characters are now escaped per RFC 2254).

- Fixed an issue that caused a server-side session leak.
- Fixed an issue where, in rare cases, reads from a table could block its deletion.
- Fixed a race condition when updating the CPU soft limit.
- Fixed behavior, where `ALTER TABLE` could fail for tables with a vector index.
- Fixed nconsistent results in some read-write transactions — conflicting writes no longer overwrite uncommitted changes.
- Fixed serializability violations in read-write transactions after shard restarts.
- Fixed a memory management issue when committing offsets in topics with automatic partitioning enabled.
- Added checks for enabled encryption in zero-copy transfers.
- Fixed an issue that could cause a VDisk to hang in local recovery after a ChunkRead error.
- Eliminated phantom VDisk appearances caused by race conditions between group creation and deletion operations.
- Improved phantom VDisks caused by races between group creation and deletion operations.
- When a session ends via attach stream, a notification is now sent.
- The coordination service now correctly returns `SCHEME_ERROR` for non-existent resources instead of the incorrect `INTERNAL_ERROR` code.
- Fixed memory handling issues and internal data consistency violations in Workload Manager and related scheduler code.
- Fixed an issue where PDisk info requests could time out when the target node was disabled or unavailable.

Version 25.2

Version 25.2.1.26

Release date: May 12, 2026.

Bug Fixes

- Fixed an LDAP authentication vulnerability: knowing the login and password of any LDAP user (including one not in a group with access to YDB), an attacker could bypass group membership checks and gain access to the cluster (injection into the LDAP user search filter; added escaping of special characters per RFC 2254).
- Fixed an issue where tablet deletion might get stuck
- Fixed an issue that caused an error when changing a table's follower
- Fixed a couple of changefeed related issues:
  - Fixed an issue where importing a table with a Utf8 primary key and an enabled changefeed could fail
  - Fixed an issue where importing a table without changefeeds could fail due to incorrect changefeed file lookup.
- Fixed an issue that could cause errors during UPSERT operations in column tables.
- Fixed an error that could cause a crash due to accessing freed memory
- Fixed an issue with duplicates in unique secondary index
- Fixed an issue with checksum mismatch error on restoration compressed backup from s3
- Fixed an issue where some queries from the TPC-H 1000 benchmark could fail
- Fixed a couple of cluster bootstrap related issues:
  - Fixed an issue where cluster bootstrap could hang when mandatory authorization was enabled.
  - Fixed an issue where it was impossible to create new databases for several minutes immediately after cluster deployment
- Fixed an issue where race condition could occur and clients receive `Could not find correct token validator` error when mising newly issued tokens before `LoginProvider` state is updated.
- Fixed an issue where named expression containing another named expression caused incorrect `VIEW` backup

Release candidate 25.2.1.10

Release date: September 21, 2025.

Functionality

- Analytical capabilities are available by default: column-oriented tables can be created without special flags, using LZ4 compression and hash partitioning. Supported operations include a wide range of DML operations (UPDATE, DELETE, UPSERT, INSERT INTO ... SELECT) and CREATE TABLE AS SELECT. Integration with dbt, Apache Airflow, Jupyter, Superset, and federated queries to S3 enables building end-to-end analytical pipelines in YDB.
- Cost-Based Optimizer is enabled by default for queries involving at least one column-oriented table but can also be enabled manually for other queries. The Cost-Based Optimizer improves query performance by determining the optimal join order and join types based on table statistics; supported hints allow fine-tuning execution plans for complex analytical queries.
- Added YDB Transfer – an asynchronous mechanism for transferring data from a topic to a table. You can create a transfer, update or delete it using YQL commands.
- Added spilling, a memory management mechanism, that temporarily offloads intermediate data arising from computations and exceeding available node RAM capacity to external storage. Spilling allows executing user queries that require processing large data volumes exceeding available node memory.
- Increased the maximum amount of time allowed for a single query to execute from 30 minutes to 2 hours.
- Added support for a user-defined Certificate Authority (CA) and Yandex Cloud Identity and Access Management (IAM) authentication in asynchronous replication.
- Enabled by default:
  - vector index for approximate vector similarity search,
  - support for client-side consumer balancing, compacted topics and transactions in YDB Topics Kafka API,
  - support for auto-partitioning topics for row-oriented tables in CDC,
  - support for auto-partitioning topics in asynchronous replication,
  - support for parameterized Decimal type,
  - support for Datetime64 data type,
  - automatic cleanup of temporary tables and directories during export to S3,
  - support for changefeeds in backup and restore operations,
  - the ability to enable followers (read replicas) for covered secondary indexes,
  - system views with history of overloaded partitions.

Bug Fixes

- Fixed CPU resource limiting for column-oriented tables in Workload Manager. Previously CPU consumption could exceed the configured limits.

Version 25.1

Version 25.1.4.18

Release date: May 12, 2026.

Functionality

- Added support for the Kafka frameworks, such as Kafka Connect, Kafka Streams, Confluent Schema Registry, Kafka Streams, Apache Flink, etc. Now YDB Topics Kafka API supports the following features:
  - client-side consumer balancing. To enable it, use the `enable_kafka_native_balancing` flag in the cluster configuration. For for information, see How consumer balancing works in Apache Kafka. When enabled, consumer balancing will work the same way in YDB Topics.
  - compacted topics. To enable topic compaction, use the `enable_topic_compactification_by_key` flag.
  - transactions. To enable transactions, use the `enable_kafka_transactions` flag.
- Added a new protocol to Node Broker that eliminates the long startup of nodes on large clusters (more than 1000 servers).

YDB UI

- Fixed an issue where not all tablets are shown for pers queue group on the tablets tab in diagnostics.
- Fixed an issue where the storage tab on the diagnostics page displayed nodes of other types in addition to storage nodes.
- Fixed a serialization issue that caused an error when opening query execution statistics.
- Changed the logic for nodes transitioning to critical state – the CPU pool, which is 75-99% full, now triggers a warning, not a critical state.

Performance

- Optimized processing of empty inputs when performing JOIN operations.

Bug fixes

- Fixed an LDAP authentication vulnerability: knowing the login and password of any LDAP user (including one not in a group with access to YDB), an attacker could bypass group membership checks and gain access to the cluster (injection into the LDAP user search filter; added escaping of special characters per RFC 2254).
- Added support for a new kind of change record in asynchronous replication — `reset` record (in addition to `update` & `erase` records).
- Fixed an issue where a replication instance with an unspecified `COMMIT_INTERVAL` option caused the process to crash.
- Fixed rare errors when reading from a topic during partition balancing.
- Fixed an issue where dedicated database deletion might leave database system tablets improperly cleaned.
- Fixed an issue that caused tablets to hang when nodes experienced critical memory shortage. Now tablets will automatically start as soon as any of the nodes frees up sufficient resources.
- Fixed an issue where only the first message from a batch was saved when writing Kafka messages, with all other messages in the batch being ignored.

Release candidate 25.1.2.7

Release date: July 14, 2025.

Functionality

- Implemented a vector index for approximate vector similarity search.
- Added support for consistent asynchronous replication.
- Added configuration mechanism V2 that simplifies the deployment of new YDB clusters and further work with them. Comparison of configuration mechanisms V1 and V2.
- Added support for the parameterized Decimal type.
- Added the ability to omit the `DECLARE` operator for query parameter type declarations. Parameter types are now automatically inferred from the provided values.
- Implemented client balancing of partitions when reading using the Kafka protocol (like Kafka itself). Previously, balancing took place on the server. This mode is enabled by setting the `enable_kafka_native_balancing` flag in the cluster configuration.
- Added support for auto-partitioning topics for row-oriented tables in CDC. This mode is enabled by setting the `enable_topic_autopartitioning_for_cdc` flag in the cluster configuration.
- Added the ability to alter the retention period of CDC topics using the `ALTER TOPIC` statement.
- Added support for the DEBEZIUM_JSON format for CDC.
- Added the ability to create changefeed streams to index tables.
- Added the ability to enable followers (read replicas) for covered secondary indexes. This mode is enabled by setting the `enable_access_to_index_impl_tables` flag in the cluster configuration.
- The scope of supported objects in backup and restore operations has been expanded:
  - Support for changefeeds (enabled with the `enable_changefeeds_export` and `enable_changefeeds_import` flags).
  - Support for views (enabled with the `enable_view_export` flag).
- Added automatic cleanup of temporary tables and directories during export to S3. This mode is enabled by setting the `enable_export_auto_dropping` flag in the cluster configuration.
- Added automatic integrity checks of backups during import, which prevent restoration from corrupted backups and protect against data loss.
- Added the ability to create views that refer to UDFs in queries.
- Added system views with information about access right settings, history of overloaded partitions - enabled by setting the `enable_followers_stats` flag in the cluster configuration, history of partitions with broken locks.
- Added new parameters to the CREATE USER and ALTER USER operators:
  - `HASH` — sets a password in encrypted form.
  - `LOGIN` and `NOLOGIN` — unlocks and blocks a user, respectively.
- Enhanced account security:

    - Added user password complexity verification.
    - Implemented automatic user lockout after a specified number of failed attempts to enter the correct password.
    - Added the ability for users to change their own passwords.
- Implemented the ability to toggle functional flags at runtime. Changes to flags that do not specify `(RequireRestart) = true` in the proto file are applied without a cluster restart.
- Changed lock behavior when shard locks exceed the limit. Once the limit is exceeded, the oldest locks (rather than the newest) are converted into full-shard locks.
- Implemented a mechanism to preserve optimistic locks in memory during graceful datashard restarts, reducing `ABORTED` errors caused by lock loss during table balancing.
- Implemented a mechanism to abort volatile transactions with the `ABORTED` status during graceful datashard restarts.
- Added support for removing `NOT NULL` constraints from a table column using the `ALTER TABLE ... ALTER COLUMN ... DROP NOT NULL` statement.
- Added a limit of 100,000 concurrent session-creation requests in the coordination service.
- Increased the maximum number of columns in the primary key from 20 to 30.
- Improved diagnostics and introspection of memory errors (#10419, #11968).
- ***(Experimental)*** Added an experimental mode with strict access control checks. This mode is enabled by setting these flags:
    - `enable_strict_acl_check` – do not allow granting rights to non-existent users and delete users with permissions;
    - `enable_strict_user_management` – enables strict checks for local users (i.e. only the cluster or database administrator can administer local users);
    - `enable_database_admin` – add the role of database administrator;

Backward Incompatible Changes

- If you are using queries that access named expressions as tables using the AS_TABLE function, update temporary over YDB to version v1.23.0-ydb-compat before updating YDB to the current version to avoid errors in query execution.

YDB UI

- Query Editor was redesigned to support partial results load - it starts displaying results when receives a chunk from the server, doesn't have to wait until the query completion. This approach allows application developers to see query results faster.
- Security Improvement: controls that are could not be activated by current user due to lack of permissions are not displayed. Users won't click and experience Access Denied error.
- Added search by tablet id on Tablets tab.
- HotKeys help tab accessible by ⌘+K key is added.
- Operations tab is added to Database page. Operations allow to list operations and cancel them.
- Cluster dashboard redesign and make it collapsable.
- JsonViewer: handle case sensitive search.
- Added code snippets for YDB SDK to connect to selected database. Such snippets must speed up development.
- Rows on Queries tab were sorted by string values after proper backend sort.
- QueryEditor: removed extra confirmation requests on leaving browser page – do not ask confirmation when it's irrelevant.

Performance

- Added support for constant folding in the query optimizer by default. This feature enhances query performance by evaluating constant expressions at compile time, thereby reducing runtime overhead and enabling faster, more efficient execution of complex static expressions.
- Added a granular timecast protocol for distributed transactions, ensuring that slowing one shard does not affect the performance of others.
- Implemented in-memory state migration on a graceful restart, preserving locks and improving transaction success rates. This reduces the execution time of long transactions by decreasing the number of retries.
- Implemented pipeline processing of internal transactions in Node Broker, accelerating the startup of dynamic nodes in the cluster.
- Improved Node Broker resilience under increased cluster load.
- Enabled evictable B-Tree indexes by default instead of non-evictable SST indexes, reducing memory consumption when storing cold data.
- Optimized memory consumption by storage nodes.
- Reduced Hive startup times to 30%.
- Optimized the distributed storage replication process.
- Optimized the header size of large binary objects in VDisk.
- Reduced memory consumption through allocator page cleaning.

Bug Fixes

- Fixed an error in the Interconnect configuration that caused performance degradation.
- Fixed an out-of-memory error that occurred when deleting very large tables by limiting the number of tablets that process this operation concurrently.
- Fixed an issue that caused accidental duplicate entries in the system tablet configuration.
- Fixed an issue where data reads took too long (seconds) during frequent table resharding operations.
- Fixed an error reading from asynchronous replicas that caused failures.
- Fixed an issue that caused rare CDC initial scan freezes.
- Fixed an issue handling incomplete schema transactions in datashards during system restart.
- Fixed an issue causing inconsistent reads from a topic when explicitly confirming a message read within a transaction; users now receive an error when attempting to confirm a message.
- Fixed an issue in which topic auto-partitioning functioned incorrectly within a transaction.
- Fixed an issue in which transactions hang when working with topics during tablet restarts.
- Fixed the "Key is out of range" error when importing data from S3-compatible storage.
- Fixed an issue in which the end of the metadata field in the cluster configuration.
- Improved the secondary index build process: the system now retries on certain errors instead of interrupting the build.
- Fixed an error executing the `RETURNING` expression in `INSERT` and `UPSERT` operations.
- Fixed an issue causing Drop Tablet operations in PQ tablets to hang during Interconnect delays.
- Fixed an error during VDisk compaction.

- Fixed an issue in which long topic-reading sessions ended with "too big inflight" errors.
- Fixed an issue where reading a topic by multiple consumers hangs if at least one partition has no incoming data.
- Fixed a rare issue with PQ tablet restarts.
- Fixed an issue in which, after updating the cluster version, Hive started subscribers in data centers without running database nodes.
- Fixed an issue in which the `Failed to set up listener on port 9092 errno# 98 (Address already in use)` error occurred during version updates.
- Fixed an error that led to a segmentation fault when a healthcheck request and a cluster-node disable request executed simultaneously.
- Fixed an issue that caused partitioning of row-oriented tables to fail when a split key was selected from access samples containing a mix of full-key and key-prefix operations (such as exact and range reads).
- Fixed an issue where the index type defaulted to `GLOBAL SYNC` despite `UNIQUE` being explicitly specified.
- Fixed an issue where topic auto-partitioning did not work when the `max_active_partition` parameter was set via `ALTER TOPIC`.
- Fixed an issue that caused `db scheme describe` to return columns out of their original creation order.

Version 24.4

Version 24.4.4.12

Release date: June 3, 2025.

Performance

- Limited the number of internal inflight configuration updates.
- Optimized memory consumption by PQ tablets.
- Optimized CPU consumption of Scheme shard and reduced query latencies by checking operation count limits before performing tablet split and merge operations.

Bug Fixes

- Fixed a rare issue of client applications hanging during transaction commit where deleting partition had been done before write quota update.
- Fixed an error in copying tables with Decimal type, which caused failures when rolling back to a previous version.
- Fixed an issue where a commit without confirmation of writing to a topic led to the blocking of the current and subsequent transactions with topics.
- Fixed transaction hanging when working with topics during tablet restart or deletion.
- Fixed issues with reading messages larger than 6Mb via Kafka API.
- Fixed memory leak during writing to the topic.
- Fixed errors in processing nullable columns and columns with UUID type in row tables.

Version 24.4.4.2

Release date: April 15, 2025

Functionality

- Enabled by default:
  - support for views
  - auto-partitioning mode for topics
  - transactions involving topics and row-oriented tables simultaneously
  - volatile distributed transactions
- Added the ability to read and write to a topic using the Kafka API without authentication.

Performance

- Enabled by default automatic secondary index selection for queries.

Bug Fixes

- Fixed an error that led to a significant decrease in reading speed from tablet followers.
- Fixed an error that caused volatile distributed transactions to sometimes wait for confirmations until the next reboot.
- Fixed a rare assertion failure (server process crash) when followers attached to leaders with an inconsistent snapshot.
- Fixed a rare datashard crash when a dropped table shard is restarted with uncommitted persistent changes.
- Fixed an error that could disrupt the order of message processing in a topic.
- Fixed a rare error that could stop reading from a topic partition.
- Fixed an issue where a transaction could hang if a user performed a control plane operation on a topic (for example, adding partitions or a consumer) while the PQ tablet is moving to another node.
- Fixed a memory leak issue with the UserInfo counter value. Because of the memory leak, a reading session would eventually return a "too big in flight" error.
- Fixed a proxy crash due to duplicate topics in a request.
- Fixed a rare bug where a user could write to a topic without any account quota being applied or consumed.
- Fixed an issue where topic deletion returned "OK" while the topic tablets persisted in a functional state. To remove such tablets, follow the instructions from the pull request.
- Fixed a rare issue that prevented the restoration of a backup for a large secondary indexed table.
- Fixed an issue that caused errors when inserting data using `UPSERT` into row-oriented tables with default values.
- Resolved a bug that caused failures when executing queries to tables with secondary indexes that returned result lists using the RETURNING * expression.

Version 24.3

Version 24.3.15.5

Release date: February 6, 2025

Functionality

- Added the ability to register a database node using a certificate. In the Node Broker the flag `AuthorizeByCertificate` has been added to enable certificate-based registration.
- Added priorities for authentication ticket through a third-party IAM provider, with the highest priority given to requests from new users. Tickets in the cache update their information with a lower priority.

Performance

- Improved tablet startup time on large clusters: 210 ms → 125 ms (SSD), 260 ms → 165 ms (HDD).

Bug Fixes

- Removed the restriction on writing values greater than 127 to the Uint8 type.
- Fixed an issue where reading small messages from a topic in small chunks significantly increased CPU load, which could lead to delays in reading and writing to the topic.
- Fixed an issue with restoring from a backup stored in S3 with path-style addressing.
- Fixed an issue with restoring from a backup that was created during an automatic table split.
- Fixed an issue with Uuid serialization for CDC.
- Fixed an issue with "frozen" locks, which could be caused by bulk operations (e.g., TTL-based deletions).
- Fixed an issue where reading from a follower of tablets sometimes caused crashes during automatic table splits.
- Fixed an issue where the coordination node successfully registered proxy servers despite a connection loss.
- Fixed an issue that occurred when opening the Embedded UI tab with information about distributed storage groups.
- Fixed an issue where the Health Check did not report time synchronization issues.
- Fixed a rare issue that caused errors during read queries.
- Fixed an uncommitted changes leak and cleaned them up on startup.
- Fixed consistency issues related to caching deleted ranges.

Version 24.3.11.14

Release date: January 9, 2025.

Functionality

- Added support for restart without downtime in a minimal fault-tolerant configuration of a cluster that uses the three-node variant of `mirror-3-dc`.
- Added new UDF Roaring Bitmap functions: AndNotWithBinary, FromUint32List, RunOptimize.

Version 24.3.11.13

Release date: December 24, 2024.

Functionality

- Introduced query tracing, a tool that allows you to view the detailed path of a request through a distributed system.
- Added support for asynchronous replication, that allows synchronizing data between YDB databases in near real time. It can also be used for data migration between databases with minimal downtime for applications interacting with these databases.
- Added support for views, which can be enabled by the cluster administrator using the `enable_views` setting in dynamic configuration.
- Extended federated query capabilities to support new external data sources: MySQL, Microsoft SQL Server, and Greenplum.
- Published documentation on deploying YDB with federated query functionality (manual setup).
- Added a new launch parameter `FQ_CONNECTOR_ENDPOINT` for YDB Docker containers that specifies an external data source connector address. Added support for TLS encryption for connections to the connector and the ability to expose the connector service port locally on the same host as the dynamic YDB node.
- Added an auto-partitioning mode for topics, where partitions can dynamically split based on load while preserving message read-order and exactly-once guarantees. The mode can be enabled by the cluster administrator using the settings `enable_topic_split_merge` and `enable_pqconfig_transactions_at_scheme_shard` in dynamic configuration.
- Added support for transactions involving topics and row-based tables, enabling transactional data transfer between tables and topics, or between topics, ensuring no data loss or duplication. Transactions can be enabled by the cluster administrator using the settings `enable_topic_service_tx` and `enable_pqconfig_transactions_at_scheme_shard` in dynamic configuration.
- Implemented Change Data Capture (CDC) for synchronous secondary indexes.
- Added support for changing record retention periods in CDC topics.
- Added support for auto-increment columns as part of a table's primary key.
- Added audit logging for user login events in YDB, session termination events in the user interface, and backup/restore operations.
- Added a system view with information about sessions installed from the database using a query.
- Added support literal default values for row-oriented tables. When inserting a new row in YDB Query default values will be assigned to the column if specified.
- Added the `version()` built-in function.
- Added support for `RETURNING` clause in queries.
- Added start/end times and authors in the metadata for backup/restore operations from S3-compatible storage.
- Added support for backup/restore of ACL for tables from/to S3-compatible storage.
- Included paths and decompression methods in query plans for reading from S3.
- Added new parsing options for timestamp/datetime fields when reading data from S3.
- Added support for the `Decimal` type in partitioning keys.
- Improved diagnostics for storage issues in HealthCheck.
- ***(Experimental)*** Added a cost-based optimizer for complex queries, involving column-oriented tables. The cost-based optimizer considers a large number of alternative execution plans for each query and selects the best one based on the cost estimate for each option. Currently, this optimizer only works with plans that contain JOIN operations.
- ***(Experimental)*** Initial version of the workload manager was implemented. It allows to create resource pools with CPU, memory and active queries count limits. Resource classifiers were implemented to assign queries to specific resource pool.
- ***(Experimental)*** Implemented automatic index selection for queries, which can be enabled via the `index_auto_choose_mode setting` in `table_service_config` in dynamic configuration.

YDB UI

- Added support for creating and viewing information on asynchronous replication instances.
- Added an indicator for auto-increment columns.
- Added a tab with information about tablets.
- Added a tab with details about distributed storage groups.
- Added a setting to trace all queries and display tracing results.
- Enhanced the PDisk page with attributes, disk space consumption details, and a button to initiate disk decommissioning.
- Added information about currently running queries.
- Added a row limit setting for query editor output and a notification when results exceed the limit.
- Added a tab to display top CPU-consuming queries over the last hour.
- Added a control to search the history and saved queries pages.
- Added the ability to cancel query execution.
- Added a shortcut to save queries in the editor.
- Separated donor disks from other disks in the UI.
- Added support for InterruptInheritance ACL and improved visualization of active ACLs.
- Added a display of the current UI version.
- Added a tab with information about the status of settings for enabling experimental functionality.

Performance

- Accelerated recovery of tables with secondary indexes from backups up to 20% according to our tests.
- Optimized Interconnect throughput.
- Improved the performance of CDC topics with thousands of partitions.
- Enhanced the Hive tablet balancing algorithm.

Bug fixes

- Fixed an issue that caused databases with a large number of tables or partitions to become non-functional during restoration from a backup. Now, if database size limits are exceeded, the restoration operation will fail, but the database will remain operational.
- Implemented a mechanism to forcibly trigger background compaction when discrepancies between the data schema and stored data are detected in DataShard. This resolves a rare issue with delays in schema changes.
- Resolved duplication of authentication tickets, which led to an increased number of requests to authentication providers.
- Fixed an invariant violation issue during the initial scan of CDC, leading to an abnormal termination of the `ydbd` server process.
- Prohibited schema changes for backup tables.
- Fixed an issue with an initial scan freezing during CDC when the table is frequently updated.
- Excluded deleted indexes from the count against the maximum index limit.
- Fixed a bug in the display of the scheduled execution time for a set of transactions (planned step).
- Fixed a problem with interruptions in blue–green deployment in large clusters caused by frequent updates to the node list.
- Resolved a rare issue that caused transaction order violations.
- Fixed an issue in the EvWrite API that resulted in incorrect memory deallocation.
- Resolved a problem with volatile transactions hanging after a restart.
- Fixed a bug in the CDC, which in some cases leads to increased CPU consumption, up to a core per CDC partition.
- Eliminated read delays occurring during and after the splitting of certain partitions.
- Fixed issues when reading data from S3.
- Corrected the calculation of the AWS signature for S3 requests.
- Resolved false positives in the HealthCheck system during database backups involving a large number of shards.

Version 24.2

Release date: August 20, 2024.

Functionality

- Added the ability to set maintenance task priorities in the cluster management system.
- Added a setting to enable stable names for cluster nodes within a tenant.
- Enabled retrieval of nested groups from the LDAP server, improved host parsing in the LDAP-configuration, and added an option to disable built-in authentication via login and password.
- Added support for authenticating dynamic nodes using SSL-certificates.
- Implemented the removal of inactive nodes from Hive without a restart.
- Improved management of inflight pings during Hive restarts in large clusters.
- Changed the order of establishing connections with nodes during Hive restarts.

YDB UI

- Added the option to set a TTL for user sessions in the configuration file.
- Added an option to sort the list of queries by `CPUTime`.
- Fixed precision loss when working with `double`, `float` data types.
- Added support for creating directories in the UI.
- Added an auto-refresh control on all pages.
- Improved ACL display.
- Enabled autocomplete in the queries editor by default.
- Added support for views.

Bug fixes

- Added a check on the size of the local transaction prior to its commit to fix errors in scheme shard operations when exporting/backing up large databases.
- Fixed an issue with duplicate results in SELECT queries when reducing quotas in DataShard.
- Fixed errors occurring during coordinator state changes.

- Fixed issues during the initial CDC scan.
- Resolved race conditions in asynchronous change delivery (asynchronous indexes, CDC).
- Fixed a crash that sometimes occurred during TTL-based deletions.
- Fixed an issue with PDisk status display in the CMS.
- Fixed an issue that might cause soft tablet transfers (drain) from a node to hang.
- Resolved an issue with the interconnect proxy stopping on a node that is running without restarts. The issue occurred when adding another node to the cluster.
- Corrected string escaping in error messages.
- Fixed an issue with managing free memory in the interconnect.
- Corrected UnreplicatedPhantoms and UnreplicatedNonPhantoms counters in VDisk.
- Fixed an issue with handling empty garbage collection requests on VDisk.
- Resolved issues with managing TVDiskControls settings through CMS.
- Fixed an issue with failing to load the data created by newer versions of VDisk.
- Fixed an issue with executing the `REPLACE INTO` queries with default values.
- Fixed errors in queries with multiple LEFT JOINs to a single string table.
- Fixed precision loss for `float`, `double` types when using CDC.

Version 24.1

Release date: July 31, 2024.

Functionality

- The Knn UDF function for precise nearest vector search has been implemented.
- The gRPC Query service has been developed, enabling the execution of all types of queries (DML, DDL) and retrieval of unlimited amounts of data.
- Integration with the LDAP protocol has been implemented, allowing the retrieval of a list of groups from external LDAP directories.

Embedded UI

- The database information tab now includes a resource consumption diagnostic dashboard, which allows users to assess the current consumption of key resources: processor cores, RAM, and distributed storage space.
- Charts for monitoring the key performance indicators of the YDB cluster have been added.

Performance

- Session timeouts for the coordination service between server and client have been optimized. Previously, the timeout was 5 seconds, which could result in a 10-second delay in identifying an unresponsive client and releasing its resources. In the new version, the check interval depends on the session's wait time, allowing for faster responses during leader changes or when acquiring distributed locks.
- CPU consumption by SchemeShard replicas has been optimized, particularly when handling rapid updates for tables with a large number of partitions.

Bug fixes

- A possible queue overflow error has been fixed. Change Data Capture now reserves the change queue capacity during the initial scan.
- A potential deadlock between receiving and sending CDC records has been fixed.
- An issue causing the loss of the mediator task queue during mediator reconnection has been fixed. This fix allows processing of the mediator task queue during resynchronization.
- A rarely occurring error has been fixed, where with volatile transactions enabled, a successful transaction confirmation result could be returned before the transaction was fully committed. Volatile transactions remain disabled by default and are still under development.
- A rare error that led to the loss of established locks and the successful confirmation of transactions that should have failed with a "Transaction Locks Invalidated" error has been fixed.
- A rare error that could result in a violation of data integrity guarantees during concurrent read and write operations on a specific key has been fixed.
- An issue causing read replicas to stop processing requests has been fixed.
- A rare error that could cause abnormal termination of database processes if there were uncommitted transactions on a table during its renaming has been fixed.
- An error in determining the status of a static group, where it was not marked as non-working when it should have been, has been fixed.
- An error involving partial commits of a distributed transaction with uncommitted changes, caused by certain race conditions with restarts, has been fixed.
- Anomalies related to reading outdated data, detected using Jepsen, have been fixed.

Version 23.4

Release date: May 14, 2024.

Performance

- Fixed an issue of increased CPU consumption by a topic actor `PERSQUEUE_PARTITION_ACTOR`.
- Optimized resource usage by SchemeBoard replicas. The greatest effect is noticeable when modifying the metadata of tables with a large number of partitions.

Bug fixes

- Fixed a bug of possible partial commit of accumulated changes when using persistent distributed transactions. This error occurs in an extremely rare combination of events, including restarting tablets that service the table partitions involved in the transaction.
- Fixed a bug involving a race condition between the table merge and garbage collection processes, which could result in garbage collection ending with an invariant violation error, leading to an abnormal termination of the `ydbd` server process.
- Fixed a bug in Blob Storage, where information about changes to the composition of a storage group might not be received in a timely manner by individual cluster nodes. As a result, reads and writes of data stored in the affected group could become blocked in rare cases, requiring manual intervention.

- Fixed a bug in Blob Storage, where data storage nodes might not start despite the correct configuration. The error occurred on systems with the experimental "blob depot" feature explicitly enabled (this feature is disabled by default).
- Fixed a bug that sometimes occurred when writing to a topic with an empty `producer_id` with turned off deduplication. It could lead to abnormal termination of the `ydbd` server process.
- Fixed a bug that caused the `ydbd` process to crash due to an incorrect session state when writing to a topic.
- Fixed a bug in displaying the metric of number of partitions in a topic, where it previously displayed an incorrect value.
- Fixed a bug causing memory leaks that appeared when copying topic data between clusters. These could cause `ydbd` server processes to terminate due to out-of-memory issues.

Version 23.3

Version 23.3.17

Release date: October 12, 2023.

Functionality

- Implemented visibility of own changes. With this feature enabled you can read changed values from the current transaction, which has not been committed yet. This functionality also allows multiple modifying operations in one transaction on a table with secondary indexes.
- Added support for column tables. It is now possible to create analytical reports based on stored data in YDB with performance comparable to specialized analytical DBMS.
- Added support for Kafka API for topics. YDB topics can now be accessed via a Kafka-compatible API designed for migrating existing applications. Support for Kafka protocol version 3.4.0 is provided.
- Added the ability to write to a topic without deduplication. This is important in cases where message processing order is not critical.
- YQL has added the capabilities to create, modify, and delete topics.
- Added support of assigning and revoking access rights using the YQL `GRANT` and `REVOKE` commands.
- Added support of DML-operations logging in the audit log.
- ***(Experimental)*** When writing messages to a topic, it is now possible to pass metadata. To enable this functionality, add `enable_topic_message_meta: true` to the configuration file.
- ***(Experimental)*** Added support for reading from topics in a transaction. It is now possible to read from topics and write to tables within a transaction, simplifying the data transfer scenario from a topic to a table. To enable this functionality, add `enable_topic_service_tx: true` to the configuration file.
- ***(Experimental)*** Added support for PostgreSQL compatibility. This involves executing SQL queries in PostgreSQL dialect on the YDB infrastructure using the PostgreSQL network protocol. With this capability, familiar PostgreSQL tools such as psql and drivers (e.g., pq for Golang and psycopg2 for Python) can be used. Queries can be developed using the familiar PostgreSQL syntax and take advantage of YDB's benefits such as horizontal scalability and fault tolerance.
- ***(Experimental)*** Added support for federated queries. This enables retrieving information from various data sources without the need to move the data into YDB. Federated queries support interaction with ClickHouse and PostgreSQL databases, as well as S3 class data stores (Object Storage). YQL queries can be used to access these databases without duplicating data between systems.

Embedded UI

- A new option `PostgreSQL` has been added to the query type selector settings, which is available when the `Enable additional query modes` parameter is enabled. Also, the query history now takes into account the syntax used when executing the query.
- The YQL query template for creating a table has been updated. Added a description of the available parameters.
- Now sorting and filtering for Storage and Nodes tables takes place on the server. To use this functionality, you need to enable the parameter `Offload tables filters and sorting to backend` in the experiments section.
- Buttons for creating, changing and deleting topics have been added to the context menu.
- Added sorting by criticality for all issues in the tree in `Healthcheck`.

Performance

- Implemented read iterators. This feature allows to separate reads and computations. Read iterators allow datashards to increase read queries throughput.
- The performance of writing to YDB topics has been optimized.
- Improved tablet balancing during node overload.

Bug fixes

- Fixed an error regarding potential blocking of reading iterators of snapshots, of which the coordinators were unaware.
- Memory leak when closing the connection in Kafka proxy has been fixed.
- Fixed an issue where snapshots taken through reading iterators may fail to recover on restarts.
- Fixed an issue with an incorrect residual predicate for the `IS NULL` condition on a column.
- Fixed an occurring verification error: `VERIFY failed: SendResult(): requirement ChunksLimiter.Take(sendBytes) failed`.
- Fixed `ALTER TABLE` for TTL on column-based tables.
- Implemented a `FeatureFlag` that allows enabling/disabling work with `CS` and `DS`.
- Fixed a 50ms time difference between coordinator time in 23-2 and 23-3.
- Fixed an error where the storage endpoint was returning extra groups when the `viewer backend` had the `node_id` parameter in the request.
- Added a usage filter to the `/storage` endpoint in the `viewer backend`.
- Fixed an issue in Storage v2 where an incorrect number was returned in the `Degraded field`.
- Fixed an issue with cancelling subscriptions from sessions during tablet restarts.
- Fixed an error where `healthcheck alerts` for storage were flickering during rolling restarts when going through a load balancer.
- Updated `CPU usage metrics` in YDB.
- Fixed an issue where `NULL` was being ignored when specifying `NOT NULL` in the table schema.
- Implemented logging of `DDL` operations in the common log.
- Implemented restriction for the YDB table attribute `add/drop` command to only work with tables and not with any other objects.

- Disabled `CloseOnIdle` for interconnect.
- Fixed the doubling of read speed in the UI.
- Fixed an issue where data could be lost on block-4-2.
- Added a check for topic name validity.
- Fixed a possible deadlock in the actor system.
- Fixed the `KqpScanArrowInChanels::AllTypesColumns` test.
- Fixed the `KqpScan::SqlInParameter` test.
- Fixed parallelism issues for OLAP queries.
- Fixed the insertion of `ClickBench` parquet files.
- Added a missing call to `CheckChangesQueueOverflow` in the general `CheckDataTxReject`.
- Fixed an error that returned an empty status in `ReadRows` API calls.
- Fixed incorrect retry behavior in the final stage of export.
- Fixed an issue with infinite quota for the number of records in a `CDC topic`.
- Fixed the import error of `string` and `parquet` columns into an `OLAP string column`.
- Fixed a crash in `KqpOlapTypes.Timestamp` under `tsan`.
- Fixed a `viewer backend` crash when attempting to execute a query against the database due to version incompatibility.
- Fixed an error where the viewer did not return a response from the `healthcheck` due to a timeout.
- Fixed an error where incorrect `ExpectedSerial` values could be saved in `Pdisks`.
- Fixed an error where database nodes were crashing due to segfault in the S3 actor.
- Fixed a race condition in `ThreadSanitizer: data race KqpService::ToDictCache-UseCache`.
- Fixed a race condition in `GetNextReadId`.
- Fixed an issue with an inflated result in `SELECT COUNT(*)` immediately after import.
- Fixed an error where `TEvScan` could return an empty dataset in the case of shard splitting.
- Added a separate `issue/error` code in case of available space exhaustion.
- Fixed a `GRPC_LIBRARY Assertion` failed error.
- Fixed an error where scanning queries on secondary indexes returned an empty result.
- Fixed validation of `CommitOffset` in `TopicAPI`.
- Reduced shared cache consumption when approaching OOM.
- Merged scheduler logic from data executer and scan executer into one class.
- Added discovery and `proxy` handlers to the query execution process in the `viewer backend`.
- Fixed an error where the `/cluster` endpoint returned the root domain name, such as `/ru`, in the `viewer backend`.
- Implemented a seamless table update scheme for `QueryService`.
- Fixed an issue where `DELETE` returned data and did not delete it.
- Fixed an error in `DELETE ON` operation in query service.
- Fixed an unexpected batching disablement in `default` schema settings.
- Fixed a triggering check `VERIFY failed: MoveUserTable(): requirement move.ReMapIndexesSize() == newTableInfo->Indexes.size()`.
- Increased the `default` timeout for `grpc-streaming`.
- Excluded unused messages and methods from `QueryService`.
- Added sorting by `Rack` in /nodes in the `viewer backend`.
- Fixed an error where sorting queries returned an error in descending order.
- Improved interaction between `QP` and `NodeWhiteboard`.
- Removed support for old parameter formats.
- Fixed an error where `DefineBox` was not being applied to disks with a static group.
- Fixed a `SIGSEGV` error in the dinnode during `CSV` import via `YDB CLI`.
- Fixed an error that caused a crash when processing `NGRpcService::TRefreshTokenImpl`.
- Implemented a `gossip protocol` for exchanging cluster resource information.
- Fixed an error in `DeserializeValuePickleV1(): requirement data.GetTransportVersion() == (ui32) NDqProto::DATA_TRANSPORT_UV_PICKLE_1_0 failed`.
- Implemented `auto-increment` columns.
- Use `UNAVAILABLE` status instead of `GENERIC_ERROR` when shard identification fails.
- Added support for rope payload in `TEvVGet`.
- Added ignoring of deprecated events.
- Fixed a crash of write sessions on an invalid topic name.
- Fixed an error in `CheckExpected(): requirement newConstr failed, message: Rewrite error, missing Distinct((id)) constraint in node FlatMap`.
- Enabled `self-heal` by default.

Version 23.2

Release date: August 14, 2023.

Functionality

- ***(Experimental)*** Implemented visibility of own changes. With this feature enabled you can read changed values from the current transaction, which has not been committed yet. This functionality also allows multiple modifying operations in one transaction on a table with secondary indexes. To enable this feature add `enable_kqp_immediate_effects: true` under `table_service_config` section into configuration file.
- ***(Experimental)*** Implemented read iterators. This feature allows to separate reads and computations. Read iterators allow datashards to increase read queries throughput. To enable this feature add `enable_kqp_data_query_source_read: true` under `table_service_config` section into configuration file.

Embedded UI

- Navigation improvements:
  - Diagnostics and Development mode switches are moved to the left panel.
  - Every page has breadcrumbs.
  - Storage groups and nodes info are moved from left buttons to tabs on the database page.
- Query history and saved queries are moved to tabs over the text editor area in query editor.
- Info tab for scheme objects displays parameters using terms from `CREATE` or `ALTER` statements.
- Added column tables support.

Performance

- For scan queries, you can now effectively search for individual rows using a primary key or secondary indexes. This can bring you a substantial performance gain in many cases. Similarly to regular queries, you need to explicitly specify its name in the query text using the `VIEW` keyword to use a secondary index.
- ***(Experimental)*** Added an option to give control of the system tablets of the database (SchemeShard, Coordinators, Mediators, SysViewProcessor) to its own Hive instead of the root Hive, and do so immediately upon creating a new database. Without this flag, the system tablets of the new database are created in the root Hive, which can negatively impact its load. Enabling this flag makes databases completely isolated in terms of load, that may be particularly relevant for installations, consisting from a roughly hundred or more databases. To enable this feature add `enable_alter_database_create_hive_first: true` under `feature_flags` section into configuration file.

Bug fixes

- Fixed a bug in the autoconfiguration of the actor system, resulting in all the load being placed on the system pool.
- Fixed a bug that caused full scanning when searching by prefix of the primary key using `LIKE`.
- Fixed bugs when interacting with datashard followers.
- Fixed bugs when working with memory in column tables.
- Fixed a bug in processing conditions for immediate transactions.
- Fixed a bug in the operation of iterator-based reads on datasharrd followers.
- Fixed a bug that caused cascading reinstallation of data delivery sessions to asynchronous indexes.
- Fixed bugs in the optimizer for scanning queries.
- Fixed a bug in the incorrect calculation of storage consumption by Hive after expanding the database.
- Fixed a bug that caused operations to hang on non-existent iterators.
- Fixed bugs when reading a range on a `NOT NULL` column.
- Fixed a bug in the replication of VDisks.
- Fixed a bug in the work of the `run_interval` option in TTL.

Version 23.1

Release date: May 5, 2023. To update to version 23.1, select the Downloads section.

Functionality

- Added initial table scan when creating a CDC changefeed. Now, you can export all the data existing at the time of changefeed creation.
- Added atomic index replacement. Now, you can atomically replace one pre-defined index with another. This operation is absolutely transparent for your application. Indexes are replaced seamlessly, with no downtime.
- Added the audit log: Event stream including data about all the operations on YDB objects.

Performance

- Improved formats of data exchanged between query stages. As a result, we accelerated SELECTs by 10% on parameterized queries and by up to 30% on write operations.
- Added autoconfiguring for the actor system pools based on the workload against them. This improves performance through more effective CPU sharing.
- Optimized the predicate logic: Processing of parameterized OR or IN constraints is automatically delegated to DataShard.
- (Experimental) For scan queries, you can now effectively search for individual rows using a primary key or secondary indexes. This can bring you a substantial gain in performance in many cases. Similarly to regular queries, to use a secondary index, you need to explicitly specify its name in the query text using the `VIEW` keyword.
- The query's computational graph is now cached at query runtime, reducing the CPU resources needed to build the graph.

Bug fixes

- Fixed bugs in the distributed data warehouse implementation. We strongly recommend all our users to upgrade to the latest version.
- Fixed the error that occurred on building an index on NOT NULL columns.
- Fixed statistics calculation with MVCC enabled.
- Fixed errors with backups.
- Fixed the race condition that occurred at splitting and deleting a table with SDC.

Version 22.5

Release date: March 7, 2023. To update to version **22.5**, select the Downloads section.

What's new

- Added changefeed configuration parameters to transfer additional information about changes to a topic.
- You can now rename tables that have TTL enabled.
- You can now manage the record retention period.

Bug fixes and improvements

- Fixed an error inserting 0 rows with a BulkUpsert.
- Fixed an error importing Date/DateTime columns from CSV.

- Fixed an error importing CSV data with line breaks.
- Fixed an error importing CSV data with NULL values.
- Improved Query Processing performance (by replacing WorkerActor with SessionActor).
- DataShard compaction now starts immediately after a split or merge.

Version 22.4

Release date: October 12, 2022. To update to version **22.4**, select the Downloads section.

What's new

- YDB Topics and Change Data Capture (CDC):
  - Introduced the new Topic API. YDB Topic is an entity for storing unstructured messages and delivering them to various subscribers.
  - Added support for the Topic API to the YDB CLI and SDK. The Topic API provides methods for message streaming writes and reads as well as topic management.
  - Added the ability to capture table updates and send change messages to a topic.
- SDK:
  - Added the ability to handle topics in the YDB SDK.
  - Added official support for the database/sql driver for working with YDB in Golang.
- Embedded UI:
  - The CDC changefeed and the secondary indexes are now displayed in the database schema hierarchy as separate objects.
  - Improved the visualization of query explain plan graphics.
  - Problem storage groups have more visibility now.
  - Various improvements based on UX research.
- Query Processing:
  - Added Query Processor 2.0, a new subsystem to execute OLTP queries with significant improvements compared to the previous version.
  - Improved write performance by up to 60%, and by up to 10% for reads.
  - Added the ability to include a NOT NULL restriction for YDB primary keys when creating tables.
  - Added support for renaming a secondary index online without shutting the service down.
  - Improved the query explain view that now also includes fields for the physical operators.
- Core:
  - For read only transactions, added consistent snapshot support that does not conflict with write transactions.
  - Added BulkUpsert support for tables with asynchronous secondary indexes.
  - Added TTL support for tables with asynchronous secondary indexes.
  - Added compression support for data export to S3.
  - Added an audit log for DDL statements.
  - Added support for authentication with static credentials.
  - Added system tables for query performance troubleshooting.

Yandex Enterprise Database changelog

Version 26.1

Version 26.1.1.ent.3

Release date: August 3, 2026.

This version includes all improvements from YDB 26.1.1.22; see the changelog. It also includes the enterprise-specific improvements listed below.

Enterprise-specific Improvements

The following changes are available in Yandex Enterprise Database in addition to the corresponding YDB build:

- Added an optimization that allows filtering rows by index columns before querying the main table, reducing the number of accesses to the main table when executing certain types of queries.
- Implemented a set of fixes in index access (StreamIndexLookup) that eliminates the possibility of rare situations where executed queries could hang, and reduces RAM consumption during query execution.
- Invalid views can now be restored from a backup. This allows restoring backups created from databases containing such views without additional actions from the administrator.
- Added support for mutual certificate-based authentication (mTLS) in the Kafka API.
- Added the `TraceId` column with the query trace identifier to the `.sys/top_queries_*` and `.sys/query_sessions` system views.

Version 25.4

Version 25.4.1.ent.2

Release date: June 17, 2026.

This version includes all improvements from YDB 25.4.1.15; see the changelog. It also includes all additional fixes listed below for version 25.2.1.ent.13.

Version 25.3

Version 25.3.1.ent.3

Release date: June 11, 2026.

This version includes all improvements from YDB 25.3.1.27; see the changelog. It also includes all additional fixes listed below for version 25.2.1.ent.13.

Version 25.2

Version 25.2.1.ent.13

Release date: June 11, 2026.

This version includes all improvements from YDB 25.2.1.26; see the changelog. It also includes a number of additional improvements ported from the current 26.1 version.

Additional Fixes

The following changes were ported from version 26.1 into supported stable versions of Yandex Enterprise Database:

- Fixed a bug that violated the sort order specified in the query when accessing system tables.
- Fixed a bug in internal state integrity check logic that in rare cases could cause a single (not mass) restart of storage nodes.
- Added an optimization that allows filtering rows by index columns before querying the main table, reducing the number of accesses to the main table when executing certain types of queries.
- Implemented a set of fixes in index access (StreamIndexLookup) that eliminates the possibility of rare situations where executed queries could hang, and reduces RAM consumption during query execution.
- Added an optimization that reduces memory consumption when processing queries with the TopSort operation (`SELECT ... ORDER BY x LIMIT n`).
- Added support for index materialization during backup and restore.
- TLI (Transaction Locks Invalidated) error messages now always include either an identifier or the path of the affected table.
- Lock metrics have been added to query statistics provided through the `.sys/query_metrics_*` system tables.
- Invalid views can now be restored from a backup. This allows restoring backups created from databases containing such views without additional actions from the administrator.

Version 25.2.1.ent.4

Release date: February 12, 2026.

New Features

- Analytical capabilities are available by default: column-oriented tables can be created without special flags, using LZ4 compression and hash partitioning. Supported operations include a wide range of DML operations (UPDATE, DELETE, UPSERT, INSERT INTO ... SELECT) and CREATE TABLE AS SELECT. Integration with dbt, Apache Airflow, Jupyter, Superset, and federated queries to S3 enables building end-to-end analytical pipelines in YDB.
- Cost-Based Optimizer is enabled by default for queries involving at least one column-oriented table but can also be enabled manually for other queries. The Cost-Based Optimizer improves query performance by determining the optimal join order and join types based on table statistics; supported hints allow fine-tuning execution plans for complex analytical queries.
- Added YDB Transfer – an asynchronous mechanism for transferring data from a topic to a table. You can create a transfer, update or delete it using YQL commands.
- Added spilling, a memory management mechanism, that temporarily offloads intermediate data arising from computations and exceeding available node RAM capacity to external storage. Spilling allows executing user queries that require processing large data volumes exceeding available node memory.
- Increased the maximum amount of time allowed for a single query to execute from 30 minutes to 2 hours.
- Added support for a user-defined Certificate Authority (CA) and Yandex Cloud Identity and Access Management (IAM) authentication in asynchronous replication.

- Enabled by default:
  - vector index for approximate vector similarity search,
  - support for client-side consumer balancing, compacted topics and transactions in YDB Topics Kafka API,
  - support for auto-partitioning topics for row-oriented tables in CDC,
  - support for auto-partitioning topics in asynchronous replication,
  - support for parameterized Decimal type,
  - support for Datetime64 data type,
  - automatic cleanup of temporary tables and directories during export to S3,
  - support for changefeeds in backup and restore operations,
  - the ability to enable followers (read replicas) for covered secondary indexes,
  - system views with history of overloaded partitions.

Bug Fixes

- Fixed CPU resource limiting for column-oriented tables in Workload Manager. Previously CPU consumption could exceed the configured limits.
- Fixed an issue where tablet deletion might get stuck
- Fixed an issue that caused an error when changing a table's follower
- Fixed a couple of changefeed related issues:
  - Fixed an issue where importing a table with a Utf8 primary key and an enabled changefeed could fail
  - Fixed an issue where importing a table without changefeeds could fail due to incorrect changefeed file lookup.
- Fixed an issue that could cause errors during UPSERT operations in column tables.
- Fixed an error that could cause a crash due to accessing freed memory
- Fixed an issue with duplicates in unique secondary index
- Fixed an issue with checksum mismatch error on restoration compressed backup from s3
- Fixed an issue where some queries from the TPC-H 1000 benchmark could fail
- Fixed a couple of cluster bootstrap related issues:
  - Fixed an issue where cluster bootstrap could hang when mandatory authorization was enabled.
  - Fixed an issue where it was impossible to create new databases for several minutes immediately after cluster deployment
- Fixed an issue where race condition could occur and clients receive `Could not find correct token validator` error when mising newly issued tokens before `LoginProvider` state is updated.

Version 25.1

Version 25.1.4.ent.8

Release date: February 12, 2026.

Bug Fixes

- Fixed an issue where named expression containing another named expression caused incorrect `VIEW` backup
- Fixed descending sorting not working in queries to system views.

Version 25.1.4.ent.3

Release date: November 25, 2025.

New Features

- Implemented a vector index for approximate vector similarity search.
- Added support for consistent asynchronous replication.
- Added configuration mechanism V2 that simplifies the deployment of new YDB clusters and further work with them. Comparison of configuration mechanisms V1 and V2.
- Added support for the parameterized Decimal type.
- Implemented client balancing of partitions when reading using the Kafka protocol (like Kafka itself). Previously, balancing took place on the server. This mode is enabled by setting the `enable_kafka_native_balancing` flag in the cluster configuration.
- Added support for auto-partitioning topics for row-oriented tables in CDC. This mode is enabled by setting the `enable_topic_autopartitioning_for_cdc` flag in the cluster configuration.
- Added the ability to alter the retention period of CDC topics using the `ALTER TOPIC` statement.
- Added support for the DEBEZIUM_JSON format for CDC.
- Added the ability to create changefeed streams to index tables.
- Added the ability to enable followers (read replicas) for covered secondary indexes. This mode is enabled by setting the `enable_access_to_index_impl_tables` flag in the cluster configuration.
- Changefeeds are now supported in backup and restore operations. To use this feature, set the `enable_changefeeds_export` and `enable_changefeeds_import` flags in the `feature_flags` section of the database or cluster configuration.
- Added automatic cleanup of temporary tables and directories during export to S3. This mode is enabled by setting the `enable_export_auto_dropping` flag in the cluster configuration.
- Added automatic integrity checks of backups during import, which prevent restoration from corrupted backups and protect against data loss.
- Added the ability to create views that refer to UDFs in queries.
- Added system views with information about access right settings, history of overloaded partitions - enabled by setting the `enable_followers_stats` flag in the cluster configuration, history of partitions with broken locks.
- Added new parameters to the CREATE USER and ALTER USER operators:
  - `HASH` — sets a password in encrypted form.
  - `LOGIN` and `NOLOGIN` — unlocks and blocks a user, respectively.
- Enhanced account security:
  - Added user password complexity verification.
  - Implemented automatic user lockout after a specified number of failed attempts to enter the correct password.
  - Added the ability for users to change their own passwords.
- Implemented the ability to toggle functional flags at runtime. Changes to flags that do not specify `(RequireRestart) = true` in the proto file are applied without a cluster restart.

- Changed lock behavior when shard locks exceed the limit. Once the limit is exceeded, the oldest locks (rather than the newest) are converted into full-shard locks.
- Implemented a mechanism to preserve optimistic locks in memory during graceful datashard restarts, reducing `ABORTED` errors caused by lock loss during table balancing.
- Implemented a mechanism to abort volatile transactions with the `ABORTED` status during graceful datashard restarts.
- Added support for removing `NOT NULL` constraints from a table column using the `ALTER TABLE ... ALTER COLUMN ... DROP NOT NULL` statement.
- Added a limit of 100,000 concurrent session-creation requests in the coordination service.
- Increased the maximum number of columns in the primary key from 20 to 30.
- Improved diagnostics and introspection of memory errors (#10419, #11968).
- ***(Experimental)*** Added an experimental mode with strict access control checks. This mode is enabled by setting these flags:
  - `enable_strict_acl_check` – do not allow granting rights to non-existent users and delete users with permissions;
  - `enable_strict_user_management` – enables strict checks for local users (i.e. only the cluster or database administrator can administer local users);
  - `enable_database_admin` – add the role of database administrator;
- Added support for the Kafka frameworks, such as Kafka Connect, Kafka Streams, Confluent Schema Registry, Kafka Streams, Apache Flink, etc. Now YDB Topics Kafka API supports the following features:
  - client-side consumer balancing. To enable it, use the `enable_kafka_native_balancing` flag in the cluster configuration. For for information, see How consumer balancing works in Apache Kafka. When enabled, consumer balancing will work the same way in YDB Topics.
  - compacted topics. To enable topic compaction, use the `enable_topic_compactification_by_key` flag.
  - transactions. To enable transactions, use the `enable_kafka_transactions` flag.
- Added a new protocol to Node Broker that eliminates the long startup of nodes on large clusters (more than 1000 servers).

Backward Incompatible Changes

- If you are using queries that access named expressions as tables using the AS_TABLE function, update temporary over YDB to version v1.23.0-ydb-compat before updating YDB to the current version to avoid errors in query execution.

YDB UI

- Query Editor was redesigned to support partial results load - it starts displaying results when receives a chunk from the server, doesn't have to wait until the query completion. This approach allows application developers to see query results faster.
- Security Improvement: controls that are could not be activated by current user due to lack of permissions are not displayed. Users won't click and experience Access Denied error.
- Added search by tablet id on Tablets tab.
- HotKeys help tab accessible by ⌘+K key is added.
- Operations tab is added to Database page. Operations allow to list operations and cancel them.
- Cluster dashboard redesign and make it collapsable.
- JsonViewer: handle case sensitive search.
- Added code snippets for YDB SDK to connect to selected database. Such snippets must speed up development.
- Rows on Queries tab were sorted by string values after proper backend sort.
- QueryEditor: removed extra confirmation requests on leaving browser page – do not ask confirmation when it's irrelevant.
- Fixed an issue where not all tablets are shown for pers queue group on the tablets tab in diagnostics.
- Fixed an issue where the storage tab on the diagnostics page displayed nodes of other types in addition to storage nodes.
- Fixed a serialization issue that caused an error when opening query execution statistics.
- Changed the logic for nodes transitioning to critical state – the CPU pool, which is 75-99% full, now triggers a warning, not a critical state.

Performance

- Added support for constant folding in the query optimizer by default. This feature enhances query performance by evaluating constant expressions at compile time, thereby reducing runtime overhead and enabling faster, more efficient execution of complex static expressions.
- Added a granular timecast protocol for distributed transactions, ensuring that slowing one shard does not affect the performance of others.
- Implemented in-memory state migration on a graceful restart, preserving locks and improving transaction success rates. This reduces the execution time of long transactions by decreasing the number of retries.
- Implemented pipeline processing of internal transactions in Node Broker, accelerating the startup of dynamic nodes in the cluster.
- Improved Node Broker resilience under increased cluster load.
- Enabled evictable B-Tree indexes by default instead of non-evictable SST indexes, reducing memory consumption when storing cold data.
- Optimized memory consumption by storage nodes.
- Reduced Hive startup times to 30%.
- Optimized the distributed storage replication process.
- Optimized the header size of large binary objects in VDisk.
- Reduced memory consumption through allocator page cleaning.
- Optimized processing of empty inputs when performing JOIN operations.

Bug Fixes

- Fixed an error in the Interconnect configuration that caused performance degradation.
- Fixed an out-of-memory error that occurred when deleting very large tables by limiting the number of tablets that process this operation concurrently.
- Fixed an issue that caused accidental duplicate entries in the system tablet configuration.
- Fixed an issue where data reads took too long (seconds) during frequent table resharding operations.
- Fixed an error reading from asynchronous replicas that caused failures.
- Fixed an issue that caused rare CDC initial scan freezes.
- Fixed an issue handling incomplete schema transactions in datashards during system restart.
- Fixed an issue causing inconsistent reads from a topic when explicitly confirming a message read within a transaction; users now receive an error when attempting to confirm a message.

- Fixed an issue in which topic auto-partitioning functioned incorrectly within a transaction.
- Fixed an issue in which transactions hang when working with topics during tablet restarts.
- Fixed the "Key is out of range" error when importing data from S3-compatible storage.
- Fixed an issue in which the end of the metadata field in the cluster configuration.
- Improved the secondary index build process: the system now retries on certain errors instead of interrupting the build.
- Fixed an error executing the `RETURNING` expression in `INSERT` and `UPSERT` operations.
- Fixed an issue causing Drop Tablet operations in PQ tablets to hang during Interconnect delays.
- Fixed an error during VDisk compaction.
- Fixed an issue in which long topic-reading sessions ended with "too big inflight" errors.
- Fixed an issue where reading a topic by multiple consumers hangs if at least one partition has no incoming data.
- Fixed a rare issue with PQ tablet restarts.
- Fixed an issue in which, after updating the cluster version, Hive started subscribers in data centers without running database nodes.
- Fixed an issue in which the `Failed to set up listener on port 9092 errno# 98 (Address already in use)` error occurred during version updates.
- Fixed an error that led to a segmentation fault when a healthcheck request and a cluster-node disable request executed simultaneously.
- Fixed an issue that caused partitioning of row-oriented tables to fail when a split key was selected from access samples containing a mix of full-key and key-prefix operations (such as exact and range reads).
- Fixed an issue where the index type defaulted to `GLOBAL SYNC` despite `UNIQUE` being explicitly specified.
- Fixed an issue where topic auto-partitioning did not work when the `max_active_partition` parameter was set via `ALTER TOPIC`.
- Fixed an issue that caused `db scheme describe` to return columns out of their original creation order.
- Added support for a new kind of change record in asynchronous replication — `reset` record (in addition to `update` & `erase` records).
- Fixed an issue where a replication instance with an unspecified `COMMIT_INTERVAL` option caused the process to crash.
- Fixed rare errors when reading from a topic during partition balancing.
- Fixed an issue where dedicated database deletion might leave database system tablets improperly cleaned.
- Fixed an issue that caused tablets to hang when nodes experienced critical memory shortage. Now tablets will automatically start as soon as any of the nodes frees up sufficient resources.
- Fixed an issue where only the first message from a batch was saved when writing Kafka messages, with all other messages in the batch being ignored.

Version 24.4

Version 24.4.4.20

Release date: November 1, 2025.

New Features

- Views are now supported in backup and restore operations. To use this feature, set the `enable_view_export` flag in the `feature_flags` section of the database or cluster configuration.
- Additional identifiers — the object path ID (`PathId`) and tablet ID (`TabletId`) — are now included in Transaction locks invalidated error messages when the table cannot be identified (Unknown table).

Version 24.4.4.15

Release date: September 19, 2025.

Performance

- Columns in `ORDER BY` statement are now considered by the optimizer when automatically selecting a secondary index. This optimization is limited to queries that reference only one table and do not include any `JOIN` operations with other tables.

Bug Fixes

- When receiving an `OperationAborted` error from S3, the export operation does not terminate with an error, but retries writing to S3.

Version 24.4.4.13

Release date: July 29, 2025.

New Features

- Added support for restart without downtime in a minimal fault-tolerant configuration of a cluster that uses the three-node variant of `mirror-3-dc`.
- Added new UDF Roaring Bitmap functions: AndNotWithBinary, FromUint32List, RunOptimize.
- Added the ability to register a database node using a certificate. In the Node Broker the flag `AuthorizeByCertificate` has been added to enable certificate-based registration.
- Added priorities for authentication ticket through a third-party IAM provider, with the highest priority given to requests from new users. Tickets in the cache update their information with a lower priority.
- Added the ability to read and write to a topic using the Kafka API without authentication.
- Enabled by default:
  - support for views
  - auto-partitioning mode for topics
  - transactions involving topics and row-oriented tables simultaneously
  - volatile distributed transactions

Performance

- Improved tablet startup time on large clusters: 210 ms → 125 ms (SSD), 260 ms → 165 ms (HDD).
- Limited the number of internal inflight configuration updates.
- Optimized memory consumption by PQ tablets.

- Optimized CPU consumption of Scheme shard and reduced query latencies by checking operation count limits before performing tablet split and merge operations.
- Automated secondary index selection is now enabled by default.

Bug Fixes

- Fixed an issue where reading small messages from a topic in small chunks significantly increased CPU load, which could lead to delays in reading and writing to the topic.
- Fixed an issue with restoring from a backup that was created during an automatic table split.
- Fixed an issue with Uuid serialization for CDC.
- Fixed an issue where reading from a follower of tablets sometimes caused crashes during automatic table splits.
- Fixed an issue where the coordination node successfully registered proxy servers despite a connection loss.
- Fixed an issue that occurred when opening the Embedded UI tab with information about distributed storage groups.
- Fixed an issue where the Health Check did not report time synchronization issues.
- Fixed a rare issue of client applications hanging during transaction commit where deleting partition had been done before write quota update.
- Fixed an error in copying tables with Decimal type, which caused failures when rolling back to a previous version.
- Fixed an issue where a commit without confirmation of writing to a topic led to the blocking of the current and subsequent transactions with topics.
- Fixed transaction hanging when working with topics during tablet restart or deletion.
- Fixed issues with reading messages larger than 6Mb via Kafka API.
- Fixed memory leak during writing to the topic.
- Fixed errors in processing nullable columns and columns with UUID type in row tables.
- Fixed an error that led to a significant decrease in reading speed from tablet followers.
- Fixed an error that caused volatile distributed transactions to sometimes wait for confirmations until the next reboot.
- Fixed a rare assertion failure (server process crash) when followers attached to leaders with an inconsistent snapshot.
- Fixed a rare datashard crash when a dropped table shard is restarted with uncommitted persistent changes.
- Fixed an error that could disrupt the order of message processing in a topic.
- Fixed a rare error that could stop reading from a topic partition.
- Fixed an issue where a transaction could hang if a user performed a control plane operation on a topic (for example, adding partitions or a consumer) while the PQ tablet is moving to another node.
- Fixed a memory leak issue with the UserInfo counter value. Because of the memory leak, a reading session would eventually return a "too big in flight" error.
- Fixed a proxy crash due to duplicate topics in a request.
- Fixed a rare bug where a user could write to a topic without any account quota being applied or consumed.
- Fixed an issue where topic deletion returned "OK" while the topic tablets persisted in a functional state. To remove such tablets, follow the instructions from the pull request.
- Fixed a rare issue that prevented the restoration of a backup for a large secondary indexed table.
- Fixed an issue that caused errors when inserting data using `UPSERT` into row-oriented tables with default values.
- Resolved a bug that caused failures when executing queries to tables with secondary indexes that returned result lists using the RETURNING * expression.

Version 24.3

Version 24.3.13.11

Release date: March 6, 2025.

Bug Fixes

- Fixed an uncommitted changes leak and cleaned them up on startup.
- Fixed consistency issues related to caching deleted ranges.
- Fixed the issue of caching negative responses to authentication requests from an LDAP-compatible user and group directory for too long.

Version 24.3.13.10

Release date: December 24, 2024.

New Features

- Introduced query tracing, a tool that allows you to view the detailed path of a request through a distributed system.
- Added support for asynchronous replication, that allows synchronizing data between YDB databases in near real time. It can also be used for data migration between databases with minimal downtime for applications interacting with these databases.
- Added support for views, which can be enabled by the cluster administrator using the `enable_views` setting in dynamic configuration.
- Extended federated query capabilities to support new external data sources: MySQL, Microsoft SQL Server, and Greenplum.
- Published documentation on deploying YDB with federated query New Features (manual setup).
- Added a new launch parameter `FQ_CONNECTOR_ENDPOINT` for YDB Docker containers that specifies an external data source connector address. Added support for TLS encryption for connections to the connector and the ability to expose the connector service port locally on the same host as the dynamic YDB node.
- Added an auto-partitioning mode for topics, where partitions can dynamically split based on load while preserving message read-order and exactly-once guarantees. The mode can be enabled by the cluster administrator using the settings `enable_topic_split_merge` and `enable_pqconfig_transactions_at_scheme_shard` in dynamic configuration.
- Added support for transactions involving topics and row-based tables, enabling transactional data transfer between tables and topics, or between topics, ensuring no data loss or duplication. Transactions can be enabled by the cluster administrator using the settings `enable_topic_service_tx` and `enable_pqconfig_transactions_at_scheme_shard` in dynamic configuration.
- Implemented Change Data Capture (CDC) for synchronous secondary indexes.
- Added support for changing record retention periods in CDC topics.
- Added support for auto-increment columns as part of a table's primary key.
- Added audit logging for user login events in YDB, session termination events in the user interface, and backup/restore operations.
- Added a system view with information about sessions installed from the database using a query.

- Added support literal default values for row-oriented tables. When inserting a new row in YDB Query default values will be assigned to the column if specified.
- Added the `version()` built-in function.
- Added support for `RETURNING` clause in queries.
- Added start/end times and authors in the metadata for backup/restore operations from S3-compatible storage.
- Added support for backup/restore of ACL for tables from/to S3-compatible storage.
- Included paths and decompression methods in query plans for reading from S3.
- Added new parsing options for timestamp/datetime fields when reading data from S3.
- Added support for the `Decimal` type in partitioning keys.
- Improved diagnostics for storage issues in HealthCheck.
- ***(Experimental)*** Added a cost-based optimizer for complex queries, involving column-oriented tables. The cost-based optimizer considers a large number of alternative execution plans for each query and selects the best one based on the cost estimate for each option. Currently, this optimizer only works with plans that contain JOIN operations.
- ***(Experimental)*** Initial version of the workload manager was implemented. It allows to create resource pools with CPU, memory and active queries count limits. Resource classifiers were implemented to assign queries to specific resource pool.
- ***(Experimental)*** Implemented automatic index selection for queries, which can be enabled via the `index_auto_choose_mode setting` in `table_service_config` in dynamic configuration.

YDB UI

- Added support for creating and viewing information on asynchronous replication instances.
- Added an indicator for auto-increment columns.
- Added a tab with information about tablets.
- Added a tab with details about distributed storage groups.
- Added a setting to trace all queries and display tracing results.
- Enhanced the PDisk page with attributes, disk space consumption details, and a button to initiate disk decommissioning.
- Added information about currently running queries.
- Added a row limit setting for query editor output and a notification when results exceed the limit.
- Added a tab to display top CPU-consuming queries over the last hour.
- Added a control to search the history and saved queries pages.
- Added the ability to cancel query execution.
- Added a shortcut to save queries in the editor.
- Separated donor disks from other disks in the UI.
- Added support for InterruptInheritance ACL and improved visualization of active ACLs.
- Added a display of the current UI version.
- Added a tab with information about the status of settings for enabling experimental New Features.

Performance

- Accelerated recovery of tables with secondary indexes from backups up to 20% according to our tests.
- Optimized Interconnect throughput.
- Improved the performance of CDC topics with thousands of partitions.
- Enhanced the Hive tablet balancing algorithm.

Bug fixes

- Fixed an issue that caused databases with a large number of tables or partitions to become non-functional during restoration from a backup. Now, if database size limits are exceeded, the restoration operation will fail, but the database will remain operational.
- Implemented a mechanism to forcibly trigger background compaction when discrepancies between the data schema and stored data are detected in DataShard. This resolves a rare issue with delays in schema changes.
- Resolved duplication of authentication tickets, which led to an increased number of requests to authentication providers.
- Fixed an invariant violation issue during the initial scan of CDC, leading to an abnormal termination of the `ydbd` server process.
- Prohibited schema changes for backup tables.
- Fixed an issue with an initial scan freezing during CDC when the table is frequently updated.
- Excluded deleted indexes from the count against the maximum index limit.
- Fixed a bug in the display of the scheduled execution time for a set of transactions (planned step).
- Fixed a problem with interruptions in blue–green deployment in large clusters caused by frequent updates to the node list.
- Resolved a rare issue that caused transaction order violations.
- Fixed an issue in the EvWrite API that resulted in incorrect memory deallocation.
- Resolved a problem with volatile transactions hanging after a restart.
- Fixed a bug in the CDC, which in some cases leads to increased CPU consumption, up to a core per CDC partition.
- Eliminated read delays occurring during and after the splitting of certain partitions.
- Fixed issues when reading data from S3.
- Corrected the calculation of the AWS signature for S3 requests.
- Resolved false positives in the HealthCheck system during database backups involving a large number of shards.
- Removed the restriction on writing values greater than 127 to the Uint8 type.
- Fixed an issue with restoring from a backup stored in S3 with path-style addressing.
- Fixed an issue with "frozen" locks, which could be caused by bulk operations (e.g., TTL-based deletions).
- Fixed a rare issue that caused errors during read queries.

Version 24.2

Version 24.2.7.1

Release date: August 20, 2024.

New Features

- Added the ability to set maintenance task priorities in the cluster management system.
- Added a setting to enable stable names for cluster nodes within a tenant.

- Enabled retrieval of nested groups from the LDAP server, improved host parsing in the LDAP-configuration, and added an option to disable built-in authentication via login and password.
- Added support for authenticating dynamic nodes using SSL-certificates.
- Implemented the removal of inactive nodes from Hive without a restart.
- Improved management of inflight pings during Hive restarts in large clusters.
- Changed the order of establishing connections with nodes during Hive restarts.

YDB UI

- Added the option to set a TTL for user sessions in the configuration file.
- Added an option to sort the list of queries by `CPUTime`.
- Fixed precision loss when working with `double`, `float` data types.
- Added support for creating directories in the UI.
- Added an auto-refresh control on all pages.
- Improved ACL display.
- Enabled autocomplete in the queries editor by default.
- Added support for views.

Bug fixes

- Added a check on the size of the local transaction prior to its commit to fix errors in scheme shard operations when exporting/backing up large databases.
- Fixed an issue with duplicate results in SELECT queries when reducing quotas in DataShard.
- Fixed errors occurring during coordinator state changes.
- Fixed issues during the initial CDC scan.
- Resolved race conditions in asynchronous change delivery (asynchronous indexes, CDC).
- Fixed a crash that sometimes occurred during TTL-based deletions.
- Fixed an issue with PDisk status display in the CMS.
- Fixed an issue that might cause soft tablet transfers (drain) from a node to hang.
- Resolved an issue with the interconnect proxy stopping on a node that is running without restarts. The issue occurred when adding another node to the cluster.
- Corrected string escaping in error messages.
- Fixed an issue with managing free memory in the interconnect.
- Corrected UnreplicatedPhantoms and UnreplicatedNonPhantoms counters in VDisk.
- Fixed an issue with handling empty garbage collection requests on VDisk.
- Resolved issues with managing TVDiskControls settings through CMS.
- Fixed an issue with failing to load the data created by newer versions of VDisk.
- Fixed an issue with executing the `REPLACE INTO` queries with default values.
- Fixed errors in queries with multiple LEFT JOINs to a single string table.
- Fixed precision loss for `float`, `double` types when using CDC.

Version 24.1

Version 24.1.18.1

Release date: July 31, 2024.

New Features

- The Knn UDF function for precise nearest vector search has been implemented.
- The gRPC Query service has been developed, enabling the execution of all types of queries (DML, DDL) and retrieval of unlimited amounts of data.
- Integration with the LDAP protocol has been implemented, allowing the retrieval of a list of groups from external LDAP directories.

Embedded UI

- The database information tab now includes a resource consumption diagnostic dashboard, which allows users to assess the current consumption of key resources: processor cores, RAM, and distributed storage space.
- Charts for monitoring the key performance indicators of the YDB cluster have been added.

Performance

- Session timeouts for the coordination service between server and client have been optimized. Previously, the timeout was 5 seconds, which could result in a 10-second delay in identifying an unresponsive client and releasing its resources. In the new version, the check interval depends on the session's wait time, allowing for faster responses during leader changes or when acquiring distributed locks.
- CPU consumption by SchemeShard replicas has been optimized, particularly when handling rapid updates for tables with a large number of partitions.

Bug fixes

- A possible queue overflow error has been fixed. Change Data Capture now reserves the change queue capacity during the initial scan.
- A potential deadlock between receiving and sending CDC records has been fixed.
- An issue causing the loss of the mediator task queue during mediator reconnection has been fixed. This fix allows processing of the mediator task queue during resynchronization.
- A rarely occurring error has been fixed, where with volatile transactions enabled, a successful transaction confirmation result could be returned before the transaction was fully committed. Volatile transactions remain disabled by default and are still under development.
- A rare error that led to the loss of established locks and the successful confirmation of transactions that should have failed with a "Transaction Locks Invalidated" error has been fixed.
- A rare error that could result in a violation of data integrity guarantees during concurrent read and write operations on a specific key has been fixed.

- An issue causing read replicas to stop processing requests has been fixed.
- A rare error that could cause abnormal termination of database processes if there were uncommitted transactions on a table during its renaming has been fixed.
- An error in determining the status of a static group, where it was not marked as non-working when it should have been, has been fixed.
- An error involving partial commits of a distributed transaction with uncommitted changes, caused by certain race conditions with restarts, has been fixed.
- Anomalies related to reading outdated data, detected using Jepsen, have been fixed.

Version 23.4

Version 23.4.11.1

Release date: May 14, 2024.

Performance

- Fixed an issue of increased CPU consumption by a topic actor `PERSQUEUE_PARTITION_ACTOR`.
- Optimized resource usage by SchemeBoard replicas. The greatest effect is noticeable when modifying the metadata of tables with a large number of partitions.

Bug fixes

- Fixed a bug of possible partial commit of accumulated changes when using persistent distributed transactions. This error occurs in an extremely rare combination of events, including restarting tablets that service the table partitions involved in the transaction.
- Fixed a bug involving a race condition between the table merge and garbage collection processes, which could result in garbage collection ending with an invariant violation error, leading to an abnormal termination of the `ydbd` server process.
- Fixed a bug in Blob Storage, where information about changes to the composition of a storage group might not be received in a timely manner by individual cluster nodes. As a result, reads and writes of data stored in the affected group could become blocked in rare cases, requiring manual intervention.
- Fixed a bug in Blob Storage, where data storage nodes might not start despite the correct configuration. The error occurred on systems with the experimental "blob depot" feature explicitly enabled (this feature is disabled by default).
- Fixed a bug that sometimes occurred when writing to a topic with an empty `producer_id` with turned off deduplication. It could lead to abnormal termination of the `ydbd` server process.
- Fixed a bug that caused the `ydbd` process to crash due to an incorrect session state when writing to a topic.
- Fixed a bug in displaying the metric of number of partitions in a topic, where it previously displayed an incorrect value.
- Fixed a bug causing memory leaks that appeared when copying topic data between clusters. These could cause `ydbd` server processes to terminate due to out-of-memory issues.

Version 23.3

Version 23.3.25.2

Release date: October 12, 2023.

New Features

- Implemented visibility of own changes. With this feature enabled you can read changed values from the current transaction, which has not been committed yet. This New Features also allows multiple modifying operations in one transaction on a table with secondary indexes.
- Added support for column tables. It is now possible to create analytical reports based on stored data in YDB with performance comparable to specialized analytical DBMS.
- Added support for Kafka API for topics. YDB topics can now be accessed via a Kafka-compatible API designed for migrating existing applications. Support for Kafka protocol version 3.4.0 is provided.
- Added the ability to write to a topic without deduplication. This is important in cases where message processing order is not critical.
- YQL has added the capabilities to create, modify, and delete topics.
- Added support of assigning and revoking access rights using the YQL `GRANT` and `REVOKE` commands.
- Added support of DML-operations logging in the audit log.
- ***(Experimental)*** When writing messages to a topic, it is now possible to pass metadata. To enable this New Features, add `enable_topic_message_meta: true` to the configuration file.
- ***(Experimental)*** Added support for reading from topics in a transaction. It is now possible to read from topics and write to tables within a transaction, simplifying the data transfer scenario from a topic to a table. To enable this New Features, add `enable_topic_service_tx: true` to the configuration file.
- ***(Experimental)*** Added support for PostgreSQL compatibility. This involves executing SQL queries in PostgreSQL dialect on the YDB infrastructure using the PostgreSQL network protocol. With this capability, familiar PostgreSQL tools such as psql and drivers (e.g., pq for Golang and psycopg2 for Python) can be used. Queries can be developed using the familiar PostgreSQL syntax and take advantage of YDB's benefits such as horizontal scalability and fault tolerance.
- ***(Experimental)*** Added support for federated queries. This enables retrieving information from various data sources without the need to move the data into YDB. Federated queries support interaction with ClickHouse and PostgreSQL databases, as well as S3 class data stores (Object Storage). YQL queries can be used to access these databases without duplicating data between systems.

Embedded UI

- A new option `PostgreSQL` has been added to the query type selector settings, which is available when the `Enable additional query modes` parameter is enabled. Also, the query history now takes into account the syntax used when executing the query.
- The YQL query template for creating a table has been updated. Added a description of the available parameters.
- Now sorting and filtering for Storage and Nodes tables takes place on the server. To use this New Features, you need to enable the parameter `Offload tables filters and sorting to backend` in the experiments section.
- Buttons for creating, changing and deleting topics have been added to the context menu.
- Added sorting by criticality for all issues in the tree in `Healthcheck`.

Performance

- Implemented read iterators. This feature allows to separate reads and computations. Read iterators allow datashards to increase read queries throughput.
- The performance of writing to YDB topics has been optimized.
- Improved tablet balancing during node overload.

Bug fixes

- Fixed an error regarding potential blocking of reading iterators of snapshots, of which the coordinators were unaware.
- Memory leak when closing the connection in Kafka proxy has been fixed.
- Fixed an issue where snapshots taken through reading iterators may fail to recover on restarts.
- Fixed an issue with an incorrect residual predicate for the `IS NULL` condition on a column.
- Fixed an occurring verification error: `VERIFY failed: SendResult(): requirement ChunksLimiter.Take(sendBytes) failed`.
- Fixed `ALTER TABLE` for TTL on column-based tables.
- Implemented a `FeatureFlag` that allows enabling/disabling work with `CS` and `DS`.
- Fixed a 50ms time difference between coordinator time in 23-2 and 23-3.
- Fixed an error where the storage endpoint was returning extra groups when the `viewer backend` had the `node_id` parameter in the request.
- Added a usage filter to the `/storage` endpoint in the `viewer backend`.
- Fixed an issue in Storage v2 where an incorrect number was returned in the `Degraded field`.
- Fixed an issue with cancelling subscriptions from sessions during tablet restarts.
- Fixed an error where `healthcheck alerts` for storage were flickering during rolling restarts when going through a load balancer.
- Updated `CPU usage metrics` in YDB.
- Fixed an issue where `NULL` was being ignored when specifying `NOT NULL` in the table schema.
- Implemented logging of `DDL` operations in the common log.
- Implemented restriction for the YDB table attribute `add/drop` command to only work with tables and not with any other objects.
- Disabled `CloseOnIdle` for interconnect.
- Fixed the doubling of read speed in the UI.
- Fixed an issue where data could be lost on block-4-2.
- Added a check for topic name validity.
- Fixed a possible deadlock in the actor system.
- Fixed the `KqpScanArrowInChanels::AllTypesColumns` test.
- Fixed the `KqpScan::SqlInParameter` test.
- Fixed parallelism issues for OLAP queries.
- Fixed the insertion of `ClickBench` parquet files.
- Added a missing call to `CheckChangesQueueOverflow` in the general `CheckDataTxReject`.
- Fixed an error that returned an empty status in `ReadRows` API calls.
- Fixed incorrect retry behavior in the final stage of export.
- Fixed an issue with infinite quota for the number of records in a `CDC topic`.
- Fixed the import error of `string` and `parquet` columns into an `OLAP string column`.
- Fixed a crash in `KqpOlapTypes.Timestamp` under `tsan`.
- Fixed a `viewer backend` crash when attempting to execute a query against the database due to version incompatibility.
- Fixed an error where the viewer did not return a response from the `healthcheck` due to a timeout.
- Fixed an error where incorrect `ExpectedSerial` values could be saved in `Pdisks`.
- Fixed an error where database nodes were crashing due to segfault in the S3 actor.
- Fixed a race condition in `ThreadSanitizer: data race KqpService::ToDictCache-UseCache`.
- Fixed a race condition in `GetNextReadId`.
- Fixed an issue with an inflated result in `SELECT COUNT(*)` immediately after import.
- Fixed an error where `TEvScan` could return an empty dataset in the case of shard splitting.
- Added a separate `issue/error` code in case of available space exhaustion.
- Fixed a `GRPC_LIBRARY Assertion` failed error.
- Fixed an error where scanning queries on secondary indexes returned an empty result.
- Fixed validation of `CommitOffset` in `TopicAPI`.
- Reduced shared cache consumption when approaching OOM.
- Merged scheduler logic from data executer and scan executer into one class.
- Added discovery and `proxy` handlers to the query execution process in the `viewer backend`.
- Fixed an error where the `/cluster` endpoint returned the root domain name, such as `/ru`, in the `viewer backend`.
- Implemented a seamless table update scheme for `QueryService`.
- Fixed an issue where `DELETE` returned data and did not delete it.
- Fixed an error in `DELETE ON` operation in query service.
- Fixed an unexpected batching disablement in `default` schema settings.
- Fixed a triggering check `VERIFY failed: MoveUserTable(): requirement move.ReMapIndexesSize() == newTableInfo->Indexes.size()`.
- Increased the `default` timeout for `grpc-streaming`.
- Excluded unused messages and methods from `QueryService`.
- Added sorting by `Rack` in /nodes in the `viewer backend`.
- Fixed an error where sorting queries returned an error in descending order.
- Improved interaction between `QP` and `NodeWhiteboard`.
- Removed support for old parameter formats.

- Fixed an error where `DefineBox` was not being applied to disks with a static group.
- Fixed a `SIGSEGV` error in the dinnode during `CSV` import via `YDB CLI`.
- Fixed an error that caused a crash when processing `NGRpcService::TRefreshTokenImpl`.
- Implemented a `gossip protocol` for exchanging cluster resource information.
- Fixed an error:

```
DeserializeValuePickleV1(): requirement data.GetTransportVersion() ==
(ui32) NDqProto::DATA_TRANSPORT_UV_PICKLE_1_0 failed
```

- Implemented `auto-increment` columns.
- Use `UNAVAILABLE` status instead of `GENERIC_ERROR` when shard identification fails.
- Added support for rope payload in `TEvVGet`.
- Added ignoring of deprecated events.
- Fixed a crash of write sessions on an invalid topic name.
- Fixed an error:

```
CheckExpected(): requirement newConstr failed, message: Rewrite error,
missing Distinct((id)) constraint in node FlatMap
```

- Enabled `self-heal` by default.

YDB CLI changelog

Version 2.35.0

Released on October 30, 2026. To update to version **2.35.0**, select the Downloads section.

Features

- Added support for recursively removing Solomon (KeyValue) volumes, resource pools, and backup collections with the `ydb scheme rmdir --recursive` command.
- Added the `--skip-storage-pool-conversion` option to the `ydb admin cluster bridge convert` command to convert only static storage groups while leaving existing storage pools and their groups outside bridge mode. These pools are not replicated to added piles until converted separately. The option requires `enable_non_uniform_storage: true` in `bridge_config`.
- Added information about pending pile operations, including the error from the last failed attempt, to the `pretty` and `json` output formats of the `ydb admin cluster bridge list` command.
- Added support for displaying the `INACTIVE` pile state in the output of the `ydb admin cluster bridge list` command.

Bug fixes

- Fixed the `ydb scheme rmdir --recursive` command skipping directories whose names start with `~`.
- Fixed the `ydb tools dump` command and the `ydb tools restore` command skipping user directories whose names start with `~`. Temporary directories whose names start with `~backup_` or `export-` remain excluded.

Version 2.34.0

Released on October 18, 2026. To update to version **2.34.0**, select the Downloads section.

Features

- Added support for OpenID Connect (OIDC) authentication using static tokens, client credentials, or device authorization. Settings can be provided through YAML files with the `--oidc-config` option, the `--oidc-*` options, environment variables, or connection profiles.
- Added support for standalone column-oriented (OLAP) tables to the `ydb tools dump` command and the `ydb tools restore` command. On clusters without support for copying column-oriented tables, dumping them requires the `--avoid-copy` option, which does not guarantee a consistent data snapshot. When restoring column-oriented tables, the `--import-data` option is not supported: `--bulk-upsert` is used automatically instead.
- Added the `ydb admin cluster bridge convert` command to convert a non-bridged cluster into a bridged one with a single pile. Conversion is irreversible. The `ydb admin cluster bridge list` command now shows whether conversion is still in progress in the `pretty` and `json` output formats.
- Added support for repeating the `--pile` option in the `ydb admin cluster bridge failover` command to disconnect multiple unavailable piles in one operation.
- Added the `--format svg` output format to the `ydb sql` command for saving query plans as SVG when using the `--explain` or `--explain-analyze` options.
- Added the `--content-based-deduplication` option to the `ydb topic create` command and the `ydb topic alter` command to configure content-based message deduplication.
- Added the `--aws-sdk-log` option to the `ydb workload sqs run read|write` commands to enable AWS SDK debug logs.
- Added support for the `setnotnull` operation, which sets the `NOT NULL` constraint, in the `ydb operation` subcommands.

Improvements

- Sped up local validation of YAML configuration selectors in the `ydb admin cluster config replace` command and the `ydb admin database config replace` command.

Bug fixes

- Fixed the `ydb scheme rmdir --recursive` command failing when a directory contains schema secrets.
- Fixed progress, speed, estimated time remaining, and final read statistics in the `ydb import file parquet` command.
- Fixed false canonical result mismatches for empty optional `String` and `Utf8` values in the `ydb workload * run --check-canonical` commands.
- Fixed a memory leak when closing producers in the `ydb workload topic run write|full` commands.
- Fixed the `ydb tools restore` command failing on `Float` and `Double` values representing NaN or infinity in local backups. Parsing errors now include the file, line, column, and problematic value.

Version 2.33.0

Released on June 23, 2026. To update to version **2.33.0**, select the Downloads section.

Features

- The AI assistant in the `ydb` interactive mode can now search the YDB documentation, providing more accurate and context-aware answers.

Version 2.32.0

Released on June 22, 2026. To update to version **2.32.0**, select the Downloads section.

Features

- Added an AI mode to the `ydb` interactive mode. Press `Ctrl+T` to switch to it.
- Added the `ydb workload fulltext` command for load testing and measuring the quality of fulltext indexes.
- Added the `SET resource_pool` command to the `ydb` interactive mode.
- Added the `--resource-pool` option to the `ydb sql` command.
- Added the `--no-consumer` option to the `ydb topic read` command for reading from a topic without a consumer.
- Added the `--partition-write-speed-mps` and `--partition-write-burst-messages` options to the `ydb topic create` command and `ydb topic alter` command.

- Added the `--partition-max-inflight-bytes` option to the `ydb workload topic` command.
- Added the `--codec kafka-batch`, `--batch-inner-codec`, `--batch-flush-interval`, `--batch-flush-size`, and `--batch-flush-message-count` options to the `ydb workload topic run write|full` commands.
- Added CPU time statistics to the `ydb workload * run` commands.

Improvements

- The `ydb scheme describe` command now prints a human-readable description for external data sources (source type, location, authentication method, database, properties, and creation time) instead of empty output.

Version 2.31.0

Released on April 20, 2026. To update to version **2.31.0**, select the Downloads section.

Features

- Added the `--stats` option to the `ydb workload * run` commands, enabling extended execution statistics collection (e.g., `--stats profile`).

Version 2.30.0

Released on April 7, 2026. To update to version **2.30.0**, select the Downloads section.

Features

- Added the `ydb config completion` command to generate shell completion scripts for bash and zsh.
- Added the `ydb export nfs` and `ydb import nfs` commands, allowing users to create and restore backups directly to/from a shared NFS directory mounted on every host in the cluster.
- Added the `--compact` option to the `ydb workload tpcc import` command.
- Added the `--tx-mode` option to the `ydb workload * run` commands, which allows setting the transaction mode (e.g., `no-tx`, `serializable-rw`, `snapshot-rw`).
- Added support for the new compaction operation in the `ydb operation` subcommands.

Improvements

- When a profile is explicitly specified with the `-p` / `--profile` option, the active profile is no longer used: all options are taken only from the specified profile, environment variables, and command line. This avoids confusion when the chosen profile was unexpectedly supplemented with settings from the active profile.

Version 2.29.0

Released on February 11, 2026. To update to version **2.29.0**, select the Downloads section.

Features

- Enhancements to the `ydb` interactive mode:
  - Introduced the `/help` command for interactive command guidance.
  - Introduced the `/config` command, providing an interactive dialog to view and customize YDB CLI settings, including:
    - Enabling or disabling autocompletion hints.
    - Enabling or disabling color output.
    - Interactively selecting a color theme from a set of predefined options, with support for cloning and customizing your own theme.
- Added a download progress bar to the `ydb update` command.
- Added the `--include-index-data` option to the `ydb export s3` command, enabling index data export.
- Added the `--index-population-mode` option to the `ydb import s3` command, allowing selection of the index population mode (e.g., `build` or `import`).
- Added the `Created by`, `Create time`, and `End time` fields to the "build index" and "execute script" operations in the `ydb operation` subcommands.
- Added unified time interval format support across YDB CLI commands. Options accepting time durations now support explicit time units (e.g., `5s`, `2m`, `1h`) while maintaining backward compatibility with plain numbers interpreted using their original default units.
- Replaced the deprecated "Keep in memory" field with the "Cache mode" field in the column families description of the `ydb scheme describe` command.

Improvements

- Improved the `ydb init` and `ydb config profile` commands with interactive menus.
- Improved progress bars: consistent MiB/GiB units, stable speed display, and a dual progress bar for the `ydb import file` command showing both in-progress and confirmed bytes.

Bug fixes

- Fixed an out-of-memory issue in the `ydb workload query run` command for queries with large result sets.
- Fixed static credentials parsing to avoid using a profile password when the username comes from another source.

Version 2.28.0

Released on December 19, 2025. To update to version **2.28.0**, select the Downloads section.

Features

- Added `snapshot-ro` and `snapshot-rw` transaction modes to the `--tx-mode` option of the `ydb table query execute` command.
- Added `NO_COLOR` environment variable support to disable ANSI colors in YDB CLI (see no-color.org).
- Added a simple progress bar for non-interactive stderr.

- Added the `omit-indexes` property to the `--item` option of the `ydb tools copy` command, allowing tables to be copied without their indexes.
- Added the `import files` subcommand to the `ydb workload vector` command to populate the table from CSV or Parquet files.
- Added the `import generate` subcommand to the `ydb workload vector` command to populate the table with random data.
- ***(Requires server v26.1+)*** Changes to previously added `ydb admin cluster state fetch` command:
  - Renamed to `ydb admin cluster diagnostics collect`.
  - Added the `--no-sanitize` option, which disables sanitization and preserves sensitive data in the output.
  - Added the `--output` option to specify the path to the output `.tar.bz2` file.

Bug fixes

- Fixed a bug where the `ydb tools restore` command could crash with a `mutex lock failure (Invalid argument)` error due to an internal race condition.
- Fixed restoration of views containing named expressions and views that access secondary indexes in the `ydb tools restore` command.

Version 2.27.0

Released on October 30, 2025. To update to version **2.27.0**, select the Downloads section.

Features

- Added the `--exclude` option to the `ydb import s3` command, allowing schema objects to be excluded from the import if their names match a pattern.
- Added transfer objects support to the `ydb tools dump` command and `ydb tools restore` command.
- Added a new `--retention-period` option to the `ydb topic` subcommands. Usage of the legacy `--retention-period-hours` option is discouraged.
- The `ydb topic consumer add` command now has a new `--availability-period` option, which overrides the consumer's retention guarantee.
- The `ydb workload vector` commands now support `build-index` and `drop-index` subcommands.
- ***(Requires server v26.1+)*** Added the `ydb admin cluster state fetch` command to collect information about cluster nodes' state and metrics.

Bug fixes

- Fixed a bug where the `ydb debug ping` command crashed on any error.

Version 2.26.0

Released on September 25, 2025. To update to version **2.26.0**, select the Downloads section.

Features

- Added the `--no-merge` and `--no-cache` options to the `ydb monitoring healthcheck` command.
- Added query compilation time statistics to the `ydb workload * run` commands.
- Added the `--retries` option to the `ydb tools restore` command, which allows setting the number of retries for every upload data request.
- ***(Requires server v25.4+)*** Added the `--replace-sys-acl` option to the `ydb tools restore` command, which specifies whether to replace the ACL for system objects.

Version 2.25.0

Released on September 1, 2025. To update to version **2.25.0**, select the Downloads section.

Features

- Added final execute statistics to the `ydb workload * run` commands.
- Added the `--start-offset` option to the `ydb topic read` command, which specifies a starting position for reading from the selected partition.
- ***(Requires server v25.3+)*** Added a new paths approach in the `ydb export s3` and `ydb import s3` commands with the new `--include` option instead of the `--item` option.
- ***(Requires server v25.3+)*** Added support for encryption features in the `ydb export s3` and `ydb import s3` commands.
- ***(Requires server v25.3+) (Experimental)*** Added the `ydb admin cluster bridge` commands to manage a cluster in bridge mode: `list`, `switchover`, `failover`, `takedown`, `rejoin`.

Improvements

- User and password authentication options are now parsed independently, allowing them to be sourced from different priority levels. For example, the username can be specified via the `--user` option while the password is retrieved from the `YDB_PASSWORD` environment variable.
- Changed the default logging level from `EMERGENCY` to `WARN` for commands that support multiple verbosity levels.

Backward incompatible changes

- Removed the `--float-mode` option from the `ydb workload tpch run` and `ydb workload tpcds run` commands. Float mode is now inferred automatically from the table schema created during the `init` phase.

Bug fixes

- Fixed a bug where the `ydb import file csv` command with the `--newline-delimited` option could get stuck when processing input with invalid data.
- Fixed an issue with the progress bar display in the `ydb workload clickbench import files` command: incorrect percentage values and excessive line breaks caused duplicate progress lines.
- Fixed a bug where the `ydb workload topic write` command could crash with an `Unknown AckedMessageId` error due to an internal race condition.

- Fixed decimal type comparison in the `ydb workload * run` commands.

Version 2.24.1

Released on July 28, 2025. To update to version **2.24.1**, select the Downloads section.

Bug fixes

- Fixed a bug where the `ydb tools dump` command silently skipped schema objects of unsupported types and created empty directories for them in the destination folder on the file system.

Version 2.24.0

Released on July 23, 2025. To update to version **2.24.0**, select the Downloads section.

Features

- Added the ability for the `ydb workload tpch` and `ydb workload tpcds` commands to use a fractional value for the `--scale` option, specifying a percentage of the full benchmark's data size and workload.
- Added the `ydb workload tpcc check` command to check TPC-C data consistency.

Improvements

- Changed the default storage type in `ydb workload * init` commands to `column` (from `row`), and the default datetime mode to `datetime32` (from `datetime64`).

Bug fixes

- Fixed an issue where the `ydb import file csv` command could get stuck during execution.

Version 2.23.0

Released on July 16, 2025. To update to version **2.23.0**, select the Downloads section.

Features

- Added the `ydb workload tpcc` command to run a TPC-C benchmark.
- Added the `ydb workload vector select` command to benchmark vector index performance and recall.
- Added the `ydb tools infer csv` command to generate a `CREATE TABLE` SQL query from a CSV data file.

Improvements

- Enhanced processing of special values (`null`, `/dev/null`, `stdout`, `cout`, `console`, `stderr`, and `cerr`) for the `--output` option in the `ydb workload * run` commands.
- The `ydb workload` commands now work with absolute paths for database scheme objects.
- Improvements in the `ydb` interactive mode:
  - Added server connection check and hotkeys description.
  - Improved inline hints.
  - Added table column names completion.
  - Added schema caching.

Bug fixes

- Fixed an issue where the `ydb tools restore` command was not working on Windows.

Version 2.22.1

Released on June 17, 2025. To update to version **2.22.1**, select the Downloads section.

Bug fixes

- Fixed an issue where the certificate was not read from a file if the path to the file was specified in the profile with the `ca-file` field.
- Fixed an issue where the `ydb workload query import` and `ydb workload clickbench import files` commands displayed number of rows instead of number of bytes in progress state.

Version 2.22.0

Released on June 4, 2025. To update to version **2.22.0**, select the Downloads section.

Features

- Added scheme object names completion in interactive mode.
- Enhanced the capabilities of the `ydb workload query` command: added `ydb workload query init`, `ydb workload query import`, and `ydb workload query clean` commands, and modified the `ydb workload query run` command. Using these commands, you can initialize tables, populate them with data, perform load testing, and clean up the data afterwards.
- Added the `--threads` option to the `ydb workload clickbench run`, `ydb workload tpch run`, and `ydb workload tpcds run` commands. This option allows to specify the number of threads sending the queries.
- ***(Requires server v25.1+) (Experimental)*** Added the `ydb admin cluster config version` command to show the configuration version (V1/V2) on nodes.

Backward incompatible changes

- Removed the `--executor` option from the `ydb workload * run` commands. The `generic` executor is now always used.

Bug fixes

- Fixed an issue where the `ydb workload * clean` commands were deleting all contents from the target directory, instead of just the tables created by the init command.

Version 2.21.0

Released on May 22, 2025. To update to version **2.21.0**, select the Downloads section.

Features

- Added the `--no-discovery` global option, which allows skipping discovery and connecting to a user-provided endpoint directly.
- Added new options for workload commands:
  - Added the `--scale` option to the `ydb workload tpch init` and `ydb workload tpcds init` commands to set the percentage of the benchmark's data size and workload to use, relative to full scale.
  - Added the `--retries` option to the `ydb workload <clickbench|tpch|tpcds> run` commands to specify maximum retry count for every request.
  - Added the `--partition-size` option to the `ydb workload <clickbench|tpcds|tpch> init` commands to set maximum partition size in megabytes for row tables.
  - Added date range parameters (`--date-to` , `--date-from`) to the `ydb workload log run` command to support uniform primary key distribution.
- Enhanced backup and restore functionality:
  - Added the `--replace` and `--verify-existence` options to the `ydb tools restore` command to control the removal of existing objects that match those in the backup before restoration.
  - Improved the `ydb tools dump` command by not saving replica tables with ASYNC REPLICATION and their changefeeds to local backups. It prevents duplication of changefeeds and reduces the amount of space the backup takes on disk.
- Enhanced CLI usability:
  - Detailed help message (`-hh`) now shows the whole subcommand tree.
  - Added automatic pair insertion for brackets in `ydb` interactive mode.
  - Added support for files with BOM (Byte Order Mark) in the `ydb import file` commands.
- ***(Requires server v25.1+) (Experimental)*** Improved the `ydb debug latency` command:
  - Added the `--min-inflight` parameter to set minimum number of concurrent requests (default: 1).
  - Added the `--percentile` option to specify custom latency percentiles.
  - Enhanced the output with additional gRPC ping measurements.

Bug fixes

- The `ydb operation get` command now properly handles running operations.
- Fixed errors in the `ydb scheme rmdir` command:
  - Fixed an issue where the command was trying to delete subdomains.
  - Fixed deletion order: external tables are now deleted before external data sources due to possible dependencies between them.
  - Added support for coordination nodes in recursive removal.
- Fixed return code of the `ydb workload * run --check-canonical` command when results differ from canonical ones.
- Fixed an issue where CLI was attempting to read parameters from stdin even without available data.
- ***(Requires server v25.1+) (Experimental)*** Fixed an authorization error in the `ydb admin database restore` command when restoring from a backup containing multiple database administrator accounts.

Version 2.20.0

Released on March 5, 2025. To update to version **2.20.0**, select the Downloads section.

Features

- Added topics support in the `ydb tools dump` and `ydb tools restore` commands. In this release, only topic settings are retained; messages are not included in the backup.
- Added coordination nodes support in the `ydb tools dump` and `ydb tools restore` commands.
- Added the new `ydb workload log import generator` command.
- Added new global options for client certificates in SSL/TLS connections:
  - `--client-cert-file` : File containing a client certificate for SSL/TLS connections (PKCS#12 or PEM-encoded).
  - `--client-cert-key-file` : File containing a PEM-encoded private key for the client certificate.
  - `--client-cert-key-password-file` : File containing a password for the private key (if the key is encrypted).
- Queries in the `ydb workload run` command are now executed in random order.
- ***(Requires server v25.1+)*** Added support for external data sources and external tables in the `ydb tools dump` and `ydb tools restore` commands.
- ***(Experimental)*** Added the `ydb admin node config init` command to initialize a directory with node configuration files.
- ***(Requires server v25.1+) (Experimental)*** Added the `ydb admin cluster config generate` command to generate a dynamic configuration file from a cluster static configuration file.
- ***(Requires server v25.1+) (Experimental)*** Added the command `ydb admin cluster dump` and the command `ydb admin cluster restore` for dumping all cluster-level data. These dumps contain a list of databases with metadata, users, and groups but do not include schema objects.
- ***(Requires server v25.1+) (Experimental)*** Added the `ydb admin database dump` and `ydb admin database restore` commands for dumping all database-level data. These dumps contain database metadata, schema objects, their data, users, and groups.
- ***(Requires server v25.1+) (Experimental)*** Added the `--dedicated-storage-section` and `--dedicated-cluster-section` options to the `ydb admin cluster config fetch` command, allowing cluster and storage config sections to be fetched separately.

Bug fixes

- Fixed a bug where the `ydb auth get-token` command attempted to authenticate twice: once while listing endpoints and again while executing the actual token request.
- Fixed a bug where the `ydb import file csv` command was saving progress even if a batch upload had failed.
- Fixed a bug where some errors could be ignored when restoring from a local backup with the `ydb tools restore` command.
- Fixed a memory leak in the data generator for the `ydb workload tpcds` benchmark.

Version 2.19.0

Released on February 5, 2025. To update to version **2.19.0**, select the Downloads section.

Features

- Added changefeeds support in the `ydb tools dump` and `ydb tools restore` commands.
- Added `CREATE TABLE` text suggestion on schema error during the `ydb import file csv` command.
- Added statistics output on the current progress of the query in the `ydb workload` command.
- Added query text to the error message if a query fails in the `ydb workload run` command.
- Added a message if the global timeout expired in the `ydb workload run` command.
- ***(Requires server v25.1+)*** Added views support in the `ydb export s3` and `ydb import s3`. Views are exported as `CREATE VIEW` YQL statements, which are executed on import.
- ***(Requires server v25.1+)*** Added the `--skip-checksum-validation` option to the `ydb import s3` command to skip server-side checksum validation.
- ***(Requires server v25.1+) (Experimental)*** Added new options for the `ydb debug ping` command: `--chain-length`, `--chain-work-duration`, `--no-tail-chain`.
- ***(Requires server v25.1+) (Experimental)*** Added new options for the `ydb admin storage fetch` command: `--dedicated-storage-section` and `--dedicated-cluster-section`.
- ***(Requires server v25.1+) (Experimental)*** Added new options for the `ydb admin storage replace` command: `--filename`, `--dedicated-cluster-yaml`, `--dedicated-storage-yaml`, `--enable-dedicated-storage-section` and `--disable-dedicated-storage-section`.

Bug fixes

- Fixed a bug where the arm64 YDB CLI binary was downloading the amd64 binary to replace itself during the `ydb update` command. To update already installed binaries to the latest arm64 version, YDB CLI should be reinstalled.
- Fixed the return code of the `ydb workload run` command.
- Fixed a bug where the `ydb workload tpch import generator` and `ydb workload tpcds import generator` commands were failing because not all tables had been created.
- Fixed a bug with backslashes in the `ydb workload` commands paths on Windows.

Version 2.18.0

Released on December 24, 2024. To update to version **2.18.0**, select the Downloads section.

Features

- Added support for views in local backups: `ydb tools dump` and `ydb tools restore`. Views are backed up as `CREATE VIEW` queries saved in the `create_view.sql` files, which can be executed to recreate the original views.
- Added new options to the `ydb workload topic run` command: `--tx-commit-interval` and `--tx-commit-messages`, allowing you to specify the interval between transaction commits in milliseconds or in the number of messages written, respectively.
- Made the `--consumer` flag in the `ydb topic read` command optional. In the non-subscriber reading mode, the partition IDs must be specified with the `--partition-ids` option. In this case, the read is performed without saving the offset commit.
- The `ydb import file csv` command now saves the import progress. Relaunching the import command will resume the process from the row where it was interrupted.
- In the `ydb workload kv` and `ydb workload stock` commands, the default value of the `--executer` option has been changed to `generic`, which makes them no longer rely on the legacy query execution infrastructure.
- Replaced the CSV format with Parquet for filling tables in the `ydb workload` benchmarks.
- ***(Requires server v25.1+) (Experimental)*** Added new `ydb admin storage` command with `fetch` and `replace` subcommands to manage server storage configuration.

Backward incompatible changes

- Replaced the `--query-settings` option with `--query-prefix` in the `ydb workload * run` command.

Bug fixes

- Fixed a bug where the `ydb workload * run` command could crash in `--dry-run` mode.
- Fixed a bug in the `ydb import file csv` where multiple columns with escaped quotes in the same row were parsed incorrectly.

Version 2.17.0

Released on December 4, 2024. To update to version **2.17.0**, select the Downloads section.

Features

- ***(Requires server v25.1+) (Experimental)*** Added the `ydb debug ping` command for performance and connectivity debugging.

Performance

- Improved performance of parallel importing data from the file system using the `ydb tools restore` command.

Bug fixes

- Fixed a bug in the table schema created by the `ydb workload tpch` command where the `partsupp` table contained an incorrect list of key columns.
- Resolved an issue where the `ydb tools restore` command failed with the error "Too much data" if the maximum value of the `--upload-batchbytes` option was set to 16 MB.

Version 2.16.0

Released on November 26, 2024. To update to version **2.16.0**, select the Downloads section.

Features

- Improved throughput of the `ydb import file csv` command by up to 3 times.
- Added support for running the stock benchmark with column-oriented tables.
- Added support for ISO 8601–formatted timestamps in the `ydb topic` commands.
- Added the `--explain-ast` option to the `ydb sql` command, which prints the query AST.
- Added ANSI SQL syntax highlighting in interactive mode.
- Added support for PostgreSQL syntax in the `ydb workload tpch` and `ydb workload tpcds` benchmarks.
- Introduced the `-c` option for the `ydb workload tpcds run` command to compare results with expected values and display differences.
- Added log events for the `ydb tools dump` and `ydb tools restore` commands.
- Enhanced the `ydb tools restore` command to display error locations.

Backward incompatible changes

- Changed the default value of the `ydb topic write` command's `--codec` option to `RAW`.

Bug fixes

- Fixed the progress bar in the `ydb workload import` command.
- Resolved an issue where restoring from a backup using the `--import-data` option could fail if the table's partitioning had changed.

Version 2.10.0

Released on June 24, 2024. To update to version **2.10.0**, select the Downloads section.

Features

- Added the `ydb sql` command that runs over QueryService and can execute any DML/DDL command.
- Added `notx` support for the `--tx-mode` option in the `ydb table query execute` command.
- Added start and end times for long-running operation descriptions (export, import).
- Added replication description support in the `ydb scheme describe` and `ydb scheme ls` commands.
- Added big datetime types support: `Date32`, `Datetime64`, `Timestamp64`, `Interval64`.
- `ydb workload` commands rework:
  - Added the `--clear` option to the `init` subcommand, allowing tables from previous runs to be removed before workload initialization.
  - Added the `ydb workload * import` command to prepopulate tables with initial content before executing benchmarks.

Backward incompatible changes

- `ydb workload` commands rework:
  - The `--path` option was moved to a specific workload level. For example: `ydb workload tpch --path some/tables/path init ...`.
  - The `--store=s3` option was changed to `--store=external-s3` in the `init` subcommand.

Bug fixes

- Fixed colors in the `PrettyTable` format

Version 2.9.0

Released on April 25, 2024. To update to version **2.9.0**, select the Downloads section.

Features

- Improved query logical plan tables: added colors, more information, fixed some bugs.
- The verbose option `-v` is supported for the `ydb workload` commands to provide debug information.
- Added an option to run the `ydb workload tpch` command with an S3 source to measure federated queries performance.
- Added the `--rate` option for `ydb workload` commands to control the transactions (or requests) per second limit.
- Added the `--use-virtual-addressing` option for S3 import/export, allowing the switch to virtual hosting of buckets for the S3 path layout.
- Improved the `ydb scheme ls` command performance due to listing directories in parallel.

Bug fixes

- Resolved an issue where extra characters were truncated during line transfers in CLI tables.
- Fixed invalid memory access in `tools restore`.
- Fixed the issue of the `--timeout` option being ignored in generic and scan queries, as well as in the import command.
- Added a 60-second timeout to version checks and CLI binary downloads to prevent infinite waiting.
- Minor bug fixes.

Version 2.8.0

Released on January 12, 2024. To update to version **2.8.0**, select the Downloads section.

Features

- Added new `ydb admin config` and `ydb admin volatile-config` commands for cluster configuration management.
- Added support for loading PostgreSQL-compatible data types by ydb import file csv|tsv|json command. Only for row-oriented tables.
- Added support for directory load from an S3-compatible storage in the ydb import s3 command. Currently only available on Linux and Mac OS.

- Added support for outputting the results of ydb table query execute, ydb yql and ydb scripting yql commands in the Apache Parquet format.
- In the ydb workload commands, the `--executer` option has been added, which allows to specify which type of queries to use.
- Added a column with median benchmark execution time in the statistics table of the ydb workload clickbench command.
- ***(Experimental)*** Added the `generic` request type to the ydb table query execute command, which allows performing DDL and DML operations, returning arbitrarily-sized results, and supporting MVCC. The command uses an experimental API, compatibility is not guaranteed.
- ***(Experimental)*** In the `ydb table query explain` command, the `--collect-diagnostics` option has been added to collect query diagnostics and save it to a file. The command uses an experimental API, compatibility is not guaranteed.

Bug fixes

- Fixed an error displaying tables in `pretty` format with Unicode characters.
- Fixed an error substituting the wrong primary key in the command `ydb tools pg-convert`.

Version 2.7.0

Released on October 23, 2023. To update to version **2.7.0**, select the Downloads section.

Features

- Added the `ydb tools pg-convert` command, which prepares a dump obtained by the pg_dump utility for loading into the YDB postgres-compatible layer.
- Added the `ydb workload query` load testing command, which loads the database with script execution queries in multiple threads.
- Added new `ydb scheme permissions list` command to list permissions.
- In the commands ydb table query execute, ydb table query explain, ydb yql, and ydb scripting yql, the `--flame-graph` option has been added, specifying the path to the file in which you need to save the visualization of query execution statistics.
- Special commands in the interactive query execution mode are now case-insensitive.
- Added validation for special commands and their parameters.
- Added table reading in the scenario with transactions in the command ydb workload transfer topic-to-table run.
- Added the `--commit-messages` option to the command ydb workload transfer topic-to-table run, specifying the number of messages in a single transaction.
- Added the options `--only-table-in-tx` and `--only-topic-in-tx` in the command ydb workload transfer topic-to-table run, specifying restrictions on the types of queries in a single transaction.
- Added new columns `Select time` and `Upsert time` in the statistics table in the command ydb workload transfer topic-to-table run.

Bug fixes

- Fixed an error when loading an empty JSON list by commands: ydb table query execute, ydb scripting yql and ydb yql.

Version 2.6.0

Released on September 7, 2023. To update to version **2.6.0**, select the Downloads section.

Features

- Added `--path` option to ydb workload tpch run, which contains the path to the directory with tables created by the ydb workload tpch init command.
- Added ydb workload transfer topic-to-table run command, which loads the database with read requests from topics and write requests to the table.
- Added the option `--consumer-prefix` in the commands ydb workload topic init, ydb workload topic run read|full, specifying prefixes of consumer names.
- Added the `--partition-ids` option in the ydb topic read command, which specifies a comma-separated list of topic partition identifiers to read from.
- Added support for CSV and TSV parameter formats in YQL query execution commands.
- The interactive mode of query execution has been redesigned. Added new interactive mode specific commands: `SET`, `EXPLAIN`, `EXPLAIN AST`. Added saving history between CLI launches and auto-completion of YQL queries.
- Added the command ydb config info, which outputs the current connection parameters without connecting to the database.
- Added the command ydb workload kv run mixed, which loads the database with write and read requests.
- The `--percentile` option in the ydb workload topic run write|read|full commands can now take floating point values.
- The default values for the `--seconds` and `--warmup` options in the ydb workload topic run write|read|full commands have been increased to 60 seconds and 5 seconds, respectively.
- Changed the default value for the `--supported-codecs` option to `RAW` in the ydb topic create and ydb topic consumer add commands.

Bug fixes

- Fixed string loss when loading with the ydb import file json command.
- Fixed ignored statistics during the warm-up of commands ydb workload topic run write|read|full.
- Fixed incomplete statistics output in the ydb scripting yql and ydb yql commands.
- Fixed incorrect output of progress bar in ydb tools dump and ydb tools restore commands.
- Fixed loading large files with the header in the ydb import file csv|tsv command.
- Fixed hanging of the ydb tools restore --import-data command.
- Fixed error `Unknown value Rejected` when executing the ydb operation list build index command.

Version 2.5.0

Released on June 20, 2023. To update to version **2.5.0**, select the Downloads section.

Features

- For the `ydb import file` command, a parameter --timeout has been added that specifies the time within which the operation should be performed on the server.
- Added a progress bar in commands ydb scheme rmdir --recursive and ydb import file.
- Added the command ydb workload kv run read-rows, which loads the database with requests to read rows using a new experimental API call ReadRows (implemented only in the main branch), which performs faster key reading than select.
- New parameters `--warmup-time`, `--percentile`, `--topic` have been added to the ydb workload topic, setting the test warm-up time, the percentile in the statistics output and the topic name, respectively.
- Added the ydb workload tpch command to run the TPC-H benchmark.
- Added the `--ordered` flag in the command ydb tools dump, which preserves the order by primary key in tables.

Performance

- The data loading speed in the `ydb import file` command has been increased by adding parallel loading. The number of threads is set by the new parameter --threads.
- A performance of the ydb import file json command has been increased by reducing the number of data copies.

Version 2.4.0

Released on May 24, 2023. To update to version **2.4.0**, select the Downloads section.

Features

- Added the ability to upload multiple files in parallel with the command ydb import file.
- Added support for deleting column tables for the command ydb scheme rmdir --recursive.
- Improved stability of the command ydb workload topic.

Version 2.3.0

Release date: May 1, 2023. To update to version **2.3.0**, select the Downloads section.

Features

- Added the interactive mode of query execution. To switch to the interactive mode, run ydb yql without arguments. This mode is experimental: backward compatibility is not guaranteed yet.
- Added the ydb index rename command for atomic replacement or renaming of a secondary index.
- Added the `ydb workload topic` command for generating the load that reads messages from topics and writes messages to topics.
- Added the --recursive option for the `ydb scheme rmdir` command. Use it to delete a directory recursively, with all its content.
- Added support for the `topic` and `coordination node` types in the ydb scheme describe command.
- Added the --commit option for the `ydb topic consumer` command. Use it to commit messages you have read.
- Added the --columns option for the `ydb import file csv|tsv` command. Use it as an alternative to the file header when specifying a column list.
- Added the --newline-delimited option for the `ydb import file csv|tsv` command. Use it to make sure that your data is newline-free. This option streamlines import by reading data from several file sections in parallel.

Bug fixes

- Fixed the bug that resulted in excessive memory and CPU utilization when executing the `ydb import file` command.

Version 2.2.0

Release date: March 3, 2023. To update to version **2.2.0**, select the Downloads section.

Features

- Fixed the error that didn't allow specifying supported compression algorithms when adding a topic consumer.
- Added support for streaming YQL scripts and queries based on options transferred via `stdin`.
- You can now use a file to provide YQL query options
- Password input requests are now output to `stderr` instead of `stdout`.
- You can now save the root CA certificate path in a profile.
- Added a global option named --profile-file to use the specified file as storage for profile settings.
- Added a new type of load testing: ydb workload clickbench.

Version 2.1.1

Release date: December 30, 2022. To update to version **2.1.1**, select the Downloads section.

Improvements

- Added support for the `--stats` option of the ydb scheme describe command for column-oriented tables.
- Added support for Parquet files to enable their import with the ydb import command.
- Added support for additional logging and retries for the ydb import command.

Version 2.1.0

Release date: November 18, 2022. To update to version **2.1.0**, select the Downloads section.

Features

- You can now create a profile non-interactively.
- Added the ydb config profile update and ydb config profile replace commands to update and replace profiles, respectively.
- Added the `-1` option for the ydb scheme ls command to enable output of a single object per row.
- You can now save the IAM service URL in a profile.
- Added support for username and password-based authentication without specifying the password.
- Added support for AWS profiles in the ydb export s3 command.

- You can now create profiles using `stdin`. For example, you can pass the YC CLI `yc ydb database get information` command output to the `ydb config profile create` command input.

Bug fixes

- Fixed the error when request results were output in JSON-array format incorrectly if they included multiple server responses.
- Fixed the error that disabled profile updates so that an incorrect profile was used.

Version 2.0.0

Release date: September 20, 2022. To update to version **2.0.0**, select the Downloads section.

Features

- Added the ability to work with topics:
  - `ydb topic create`: Create a topic.
  - `ydb topic alter`: Update a topic.
  - `ydb topic write`: Write data to a topic.
  - `ydb topic read`: Read data from a topic.
  - `ydb topic drop`: Delete a topic.
- Added a new type of load testing:
  - `ydb workload kv init`: Create a table for kv load testing.
  - `ydb workload kv run`: Apply one of three types of load: run multiple `UPSERT` sessions, run multiple `INSERT` sessions, or run multiple sessions of GET requests by primary key.
  - `ydb workload kv clean`: Delete a test table.
- Added the ability to disable current active profile (see the `ydb config profile deactivate` command).
- Added the ability to delete a profile non-interactively with no commit (see the `--force` option under the `ydb config profile remove` command).
- Added CDC support for the `ydb scheme describe` command.
- Added the ability to view the current DB status (see the `ydb monitoring healthcheck` command).
- Added the ability to view authentication information (token) to be sent with DB queries under the current authentication settings (see the `ydb auth get-token` command).
- Added the ability for the `ydb import` command to read data from stdin.
- Added the ability to import data in JSON format from a file or stdin (see the `ydb import file json` command).

Improvements

- Improved command processing. Improved the accuracy of user input parsing and validation.

Version 1.9.1

Release date: June 25, 2022. To update to version **1.9.1**, select the Downloads section.

Features

- Added the ability to compress data when exporting it to S3-compatible storage (see the `--compression` option of the ydb export s3 command).
- Added the ability to manage new YDB CLI version availability auto checks (see the `--disable-checks` and `--enable-checks` options of the ydb version command).

Security changelog

Fixed in YDB 22.4.44, 2022-11-28

CVE-2022-28228

Out-of-bounds read was discovered in YDB server. An attacker could construct a query with an insert statement that would allow them to access confidential information or cause a crash.

Link to CVE: https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2022-28228.

Credits: Maxim Arnold.

Fixed in YDB Go SDK v3.53.3, 2023-10-17

CVE-2023-45825

Token in custom credentials object can leak through logs.

Link to CVE: https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2023-45825.

Credits: Sergey Foster.

Fixed in YDB 25.3.1.25, 2026-04-03

CVE-2026-10549

LDAP filter injection vulnerability allows an attacker with valid LDAP credentials to bypass group membership checks and gain unauthorized access to the database.

Link to CVE: https://www.cve.org/CVERecord?id=CVE-2026-10549.
